In England sewers were originally constructed for the purpose of conveying storm waters from roofs, street surfaces, yards, and so forth, to the nearest rivers or streams, and the admission of fæcal matters into sewers was forbidden by law. When the water-carriage system of sewage came into vogue in the early part of the last century sewers were gradually utilized for the reception of the overflow of liquids from cesspools and for the removal of house drainage. The admission of excremental matters into sewers was not only legalized, but made compulsory in London in 1847, and in the rest of England in the following year.

Prior to that time sewers were constructed with large open shafts placed at or near to the sidewalks for the admission of surface waters; these shafts were untrapped and were covered with grids of large size. There were no ventilating shafts in the centre of the carriageways, nor were there any side entrances for gaining access to the sewers. Ventilation was therefore effected by the gully shafts, the effluvium from which gave rise to very general complaint in London as early as 1830, and as the use of sewers for the conveyance of fæcal matter was extended, these complaints became intensified. Public attention was consequently directed to the subject with the object of devising some means of remedying this evil, with the result that in London and some other English towns the gullies were tapped and shafts were erected in the centre of the carriageways to admit of the escape of the sewer gases at points as far removed from the houses and sidewalks as practicable; this system was completed in the city of London by the end of 1848. The arrangement, however, did not remove the nuisance; it merely transferred it from the sides to the centre of the streets, most of which are narrow, with carriageways largely used by pedestrians.

In 1852 the English Board of Health advised the ventilation of public sewers, and in 1878 "suggestions" as to the preparations of plans for main sewers, etc., were issued under the direction of Sir Robert Rawlinson, C.B., the chief engineering inspector to the local government board (the successors to the Board of Health). The local government board advocated:—

(a) Sewers constructed in straight lines.

(b) Manholes or lampholes at each change of direction and gradient, and terminating at the street surface.

(c) The trapping and ventilation of all house drains.

The advice given by the Government Department has been generally followed by English engineers in the design of drainage works in Great Britain, but the sewer-gas problem still remains unsolved, and the nuisance from sewer emanations continues. . . . Numerous proposals have in the past been made for abating the nuisance caused by sewer gas; for example, mechanical ventilation by means of fans, specially constructed shafts with furnaces to extract and consume the gases, flexible screens to regulate the air currents, connections with factory chimneys, and numerous methods of chemical deterioration were suggested and tried more than fifty years ago with varying results.

The old fallacy that the application of the principles successfully used in ventilating mines would be equally successful if applied to sewers is still retained by some theorists. Those who know how widely dissimilar the conditions are can readily appreciate that the remedial measures which prove successful in the one case may be worthless in the other. Plenum or vacuum systems, either separately or in conjunction, can be applied to mines, sufficiency of power being the principal factor; but in sewers dependent on water-sealed drain traps the application of power sufficient to produce an effective current of air throughout a large system is impracticable.

Most municipal engineers are conversant with the methods here referred to, and doubtless with many others too numerous to mention. They are well aware of the conditions that have to be met and of the impracticability of the suggestions put forward by many inventors, whose proposals although sometimes of undoubted ingenuity, are generally found lacking in essential points.

Among the earliest suggestions should be mentioned those of deodorizing the sewer gases by the admixture of chlorine gas and other chemically produced gases, the application of vegetable charcoal as a deodorizer, and the admission of smoke from factory chimneys forced into the sewer by water-driven fans.

The oxidizing effect of charcoal, which had been determined by the researches of Lowitz, Saussure, Thenard and others in the latter part of the eighteenth century, was, at a later period, investigated by Drs. Stenhouse, Grace-Calvert, Letheby, and others; and under the direction of Colonel Haywood, when city engineer of London, this material was utilized for purifying sewer air by means of trays inserted in the ventilating shafts. Several mechanical arrangements were devised for the practical application of charcoal to this use, notably those of Messrs. Bean and Burgess, and later the spiral tray ventilator of Mr. Baldwin Latham.

The ventilator devised by the last-named gentleman possessed many advantages over the arrangements which preceded it, but in practical use it was found that charcoal, however skilfully applied, rapidly lost its power of deodorization, mainly owing to the moist atmosphere with which it was necessarily brought into contact. Charcoal, therefore, failed to act as a useful deodorizer unless the ventilators were recharged with it very frequently. The air currents also within the sewers were reduced by its introduction. This was fully recognized by Lieut.-Colonel Haywood and Dr. Letheby, who were careful to point out that, while charcoal diminished the escape of effluvium into the streets, it was essential that the dilution of the gases generated in the sewers should not be so lessened by the diminished air supply as to render the atmosphere in the sewers dangerous to the men who work in them. These investigations, however, candidly admitted that, on the other hand, the diminution of the air currents did not appear to have any appreciable effect on the condition of the air within the sewers. The use of this material has been abandoned in the city of London and most other British towns where it had been tried.

The necessity for ventilating sewers conveying fæcal matter was generally recognized by most of the leading English engineers, notably by such pioneers as Mr. Frank Foster, Sir Joseph Bazalgette and Lieut.-Colonel Haywood, engineers whose names are well known in connection with the main drainage of London. Recent research, however, indicates that this view must be accepted with some reservation.

Since the period more particularly referred to (1840-70) many methods have been tried experimentally in towns in Great Britain, and much has been written on the subject, not infrequently by those who have had no opportunity for personal research. The author has had the advantage of closely studying the practical aspect of the problem, first under the direction of Lieut.-Colonel Haywood in the city of London, subsequently in other British towns, and more recently in conjunction with Prof. Delepine and other experts in Manchester.

---

[*] Paper read at the recent Congress of the Royal Institute of Public Health in Berlin.

[†] City Surveyor of Manchester, England.

He proposes in the first place briefly to refer to the systems in use in some of the principal English and American towns. A few years ago information was kindly furnished to him by the municipal engineers of upwards of sixty of the principal towns in the United Kingdom, and of several important towns in Canada and the United States, from which it appears that the methods adopted in various towns differ considerably, even in cases where the local conditions are somewhat similar.

For example, we find that Belfast adopted a system of ventilation at the surface of the streets somewhat similar to that already described in relation to the city of London, Birmingham a combination of surface grids and high ventilating shafts, Bristol practically unventilated sewers, and Leicester ventilation by openings at the street surface, superseded by high shaft ventilation.

The cities of Buffalo, Chicago, Detroit, Minneapolis, Philadelphia, Washington, Boston (U.S.), and Toronto adopted surface ventilation with—it is alleged—fairly satisfactory results, the house drains being cut off from the sewers by intercepting taps in seven out of the eight cities named.

Of the sixty towns in England from which information has been derived, we find that eight towns adopted ventilation by surface grids only; five, a complete system of trapped house drains; four, untrapped street gullies; twenty, surface ventilation supplemented by high shafts; twenty-three, a combination of surface inlets and high shaft outlets; four, trapped drains, and sewers ventilated by high shafts only. The sizes given of the ventilating pipes and shafts vary from 4 in. to 12 in. in diameter, according to the size of the sewer. These are usually placed about 150 yds. apart, and in the majority of cases they are fixed against buildings.

In one town the ventilating shafts are supplemented by brick structures 42 ft. in height, with a sectional area of 9 sup. ft.

Bristol.—The method adopted at Bristol is of special interest, as that city is an exception to the rule prevailing elsewhere, being the only large town in England in which no attempt has been made to ventilate the sewers systematically, but the author is informed that the sewer workmen in that city have met with no accident due to poisoning, suffocation, or explosion for many years, although the sewage is combined with trade refuse from breweries, soapworks, tobacco manufactories, cocoa works, tanneries, and so on. The death-rate also compares favorably with that of other towns of similar size and character, being 12.71 per 1,000 in 1911.

In one town, where the brewing industry forms a large proportion of the trade, the sewers are ventilated by connections with tall chimneys. Surface ventilators are not used owing to the objectionable smell arising from the brewery refuse, and the sewers in the residential portions of the town are not directly connected with the main drainage system; sewers in the residential areas are ventilated by high shafts. In another town situated on the South Coast of England the sewage is practically free from trade refuse, but considerable difficulties have been experienced in dealing with the nuisance from sewer ventilators, and many methods, such as open gratings, tall shafts, specially devised [illegible] ventilators, have been tried to obviate the nuisance, but these systems have been found unsatisfactory and [illegible] either wholly or partially.

Taking as another example a [illegible] town in the South-West of England, where the sewage is [illegible] domestic character, there are no [illegible]. Another [illegible] will be found by a residential town of [illegible] far removed from the place last referred to. There is no system of sewer ventilation, the sewage is of a domestic character, the house drains are trapped. Some of the sewers have flat gradients and flushing is resorted to. The public health and death-rate compare favorably with other towns of the same size and character.

In forty-seven of the towns previously referred to the flushing and cleansing of the sewers is systematically carried out. In eleven the sewers have little fall; in four the falls are considerable; in thirty-two the gradients vary; in seven the sewers that have flat gradients are flushed. In six (some of the latter being of considerable size) the sewers are not flushed.

In most of the American towns from which information has been received flushing is systematically carried out.

From the foregoing remarks it will be seen that the modern practice regarding sewer ventilation in England varies greatly, and where ventilation on a uniform system has been attempted the methods adopted have in most cases been subsequently modified to meet the difficulties that have arisen. When nuisance has been experienced by smell from ventilators terminating at the street surface, the remedy most generally adopted by English engineers has been the substitution of vertical shafts fixed in suitable positions and supported by buildings or independently. This arrangement affords a better diffusion of the gases emanating from the sewers, and frequently obviates the complaints by transferring the nuisance from the surface of the streets to a higher point, but it cannot be accepted as a satisfactory solution of the problem. In the city of Manchester the tramway standards have for some years past been utilized as sewer ventilators, and the results have been fairly satisfactory.

Air Currents in Sewers.—The direction and velocity of the flow of air in sewers have been carefully investigated for a period of upwards of sixty years in several towns in England, commencing with the well-known series of experiments conducted in the city of London under the direction of Lieut.-Colonel Haywood about the middle of the last century.

Temperature observations conducted by the author in London and in Manchester show that the conditions in winter and in summer are reversed, the air in the sewers being warmer than the external air in winter and cooler in summer. These conditions, however, vary largely with climate and the character of the sewage, and the latter varies materially in different parts of some large towns where manufactories predominate. Some twenty-five years ago the author made an investigation of air currents in sewers and in pipe ventilators. A number of metal and earthenware pipes varying in diameter and in height were erected; some were placed vertically, both with and without bends, others were erected at different angles for the purpose of experiment. It was found that each pair of right-angle bends diminished the efficiency of an ordinary 4-in. metal pipe in calm weather by from 7 to 10 per cent., but this was largely varied when there was wind. The experiments were carried on continuously for eight months, and the pipes were afterwards used for ascertaining the extracting value of different kinds of cowls. Some of the cowls tested were found useful under certain conditions in preventing down draught, and some of them increased the up current in windy weather.

In experiments on two [illegible] lengths of 4-in. cast-iron ventilating pipe of heavy section it was found that under favorable conditions the heat of the sun's rays was sufficient to alter the direction of the air currents in a length of 76 ft. [illegible] diameter [illegible] drain laid with a fall of 1 in 45. One pipe experimented upon was exposed to the southeast and the other to the northwest. With three exceptions the pipe exposed to the southeast was the upcast shaft in the earlier part of the day and the downcast shaft shortly after the sun's ray passed to the other side of the building. The exceptions occurred on days when the wind was high. The experiments were conducted on these latter pipes during hot weather only.

The observations on air currents in sewers showed that where sufficient free openings were provided the direction and force of the wind exercised a great influence and overbalanced all other local conditions due to temperature, gradients, character of sewage, and so forth.

Before the instruments were allowed to record, it was found necessary to restore the normal conditions within the sewer which are invariably disturbed by the opening of manhole or side entrance covers for the purpose of entry when placing the recording instruments in position. To effect this the writer devised a small case of sufficient size to hold each anemometer. At opposite sides, and facing the fan of the anemometer, were hinged doors; these were opened by pneumatic pressure applied by a small tube brought to the surface. The doors were balanced to close when the pressure was released. By this means the instruments were not brought into use until the normal conditions within the sewer were restored. In order to check the record of each instrument while exposed to the action of the air currents, two anemometers were placed side by side suspended in boxes from the crown of the sewer, and an interval of twenty minutes was allowed to elapse before these instruments were independently brought into action by the means described. Eight instruments in all were used and were carefully corrected from time to time during the progress of the work.

Records were taken under similar conditions with the ventilating spaces in the manhole covers closed and open for a distance of 1 mile on each side of the point of observation, and the results differed so slightly that the author came to the conclusion that the effect produced within the sewer by the ordinary type of ventilating cover was negligible. On the other hand, he found that the action of the wind and variation between internal and external temperatures on the open end of a large sewer, such as a storm overflow, will produce a very material current of air for a considerable distance along the sewer, but the velocity of the current will gradually diminish, and in time cease altogether.

Effect of Wind Pressure.—Where surface ventilating covers are used, wind pressure has undoubtedly an effect upon the air within the sewers, but even with high winds the author has found the effects much smaller than what has often been attributed to this cause.

These remarks apply to large sewers, sufficient for a man to enter. In the case of smaller sewers—pipes varying from 12 in. to 18 in. in diameter—he has found the effect of wind pressure on surface ventilators more pronounced.

In the type of ventilating manhole which has hitherto been in use in the city of Manchester, the proportionate ventilating area amounts to:—

24.5 p.c. of the cross sectional area of 12 in. diameter sewer.
2.7 " " " " " 3 ft. " "
.98 " " " " " 5 ft. " "
.24 " " " " " [illegible] ft. " "

The distances between the ventilating manholes varies from 100 yds. to 150 yds. in the case of the smaller sewers, and from 150 yds. to 300 yds. in the case of the larger sewers. It will therefore be seen that the effect or air pressures under such conditions must of necessity be much less in sewers of large section than in those of a smaller type.

The results of the author's observations may be briefly summarized as follows:—

(a) Where shaft ventilation only is relied upon, some of the shafts become inlets and others outlets.

(b) These conditions are not continuous, the directions of the air currents are at times reversed, the outlets acting as inlets, and vice versâ.

(c) The air currents within the sewers are governed to a large extent by the differences between the external and internal temperature, the flow of sewage, the construction and character of the sewer and other local circumstances.

(d) All these conditions are neutralized, and at times reversed by the change of direction and force of the wind.

(e) Ventilation by metal shafts is affected, and in some cases materially assisted, by the heat of the sun.

(f) No general rule can be laid down which would be applicable to all cases and under all conditions.

(g) Under normal conditions, in properly constructed and regularly flushed sewers not receiving trade refuse, the perceptible odors are less when they are unventilated than when ventilated.

(h) Air currents do not invariably flow from lower to higher levels, the reverse being frequently the case even where gradients are steep.

(i) Air in sewers in partial use is generally more offensive than that in similar sewers which are used to their full or nearly full capacity, other conditions being equal.

(j) That the regular and efficient flushing of sewers with fresh water is a more important desideratum than the introduction of large volumes of air. A case in support of this view may be quoted where intermediate manholes were inserted in an old sewer in fair condition, which increased the ventilation openings by 100 per cent., but did not appreciably improve the condition of the air within the sewer. Flushing was resorted to and a marked improvement was immediately effected.

(k) All methods which replace or retard natural ventilation are inadvisable except under very exceptional circumstances.

(l) Ventilation of sewers is necessary for the safety of the workmen, and for the free escape of air when sewers are rapidly filled in times of storm.

(m) Methods usually adopted in the ventilation of mines cannot be successfully applied to sewers.

Manchester Corporation's Investigations.—In 1902 the Manchester Corporation appointed a special committee with a twofold purpose: First, to determine—on the generally accepted hypothesis that the ventilation of sewers is necessary—the best method of accomplishing this object; secondly, to investigate the composition of sewer air bacteriologically and chemically obtaining under varying conditions, such as are to be found in the Manchester city sewers, and to determine as far as practicable the influence of sewer emanations on health.

The committee appointed Prof. Delepine, M.B., C.M., M.Sc., director of Public Health Laboratory, Manchester University; Dr. Fowler, D.Sc., F.I.C., consulting chemist, Davyhulme sewage works; and the author, to investigate and report. Prof. Delepine undertook the bacteriological work, Dr. Fowler the chemical work, and the author the experimental installations, investigation of air currents, etc.

As a rule, when matters of public interest are about to be officially investigated in England, numerous remedies are suggested by irresponsible persons from outside. These were anticipated by advertisement in the public press intimating that the special committee were prepared to receive particulars of methods for improving the ventilation of sewers. In response to this invitation twenty replies were received. Most of them contained particulars of some proprietary arrangement or method of ventilating sewers. Each case was carefully considered, and four of those who responded were invited to furnish additional particulars, and after further consideration arrangements were made for a practical test of the method advocated in each of these four cases, which will here be referred to by the letters A, B, C, and D respectively.

Method A consisted of an electrically driven fan to extract air from the sewers and discharge it through an outlet shaft into the open air, fresh air being admitted to the sewers through inlet shafts fixed at suitable points to replace that extracted. The fan used in the experiments was 20 in. in diameter, and had a velocity of 650 revolutions per minute. It was driven by a 4 b.h.p. electric motor, placed in a brick chamber under the roadway. The upcast shaft was of steel, 20 in. in diameter, with an outlet 28 ft. above the road level. The base of the shaft was concreted into the side of the fan chamber and connected to it by a concrete duct. There were twenty-two fresh-air inlet shafts, 4 in. in diameter, varying from 5 ft. to 30 ft. high. Twenty were fitted with inlet caps by means of which the amount of air admitted at each inlet was adjusted so that the extracting power of the fan could be equally distributed throughout the whole system to be ventilated.

The area experimented upon in this case was 39½ acres. The sewers within that area has a capacity of about 25,000 cu. ft., and the resident population was about 3,000. The area included two cotton mills, an india-rubber works, a soapworks, an artificial manure factory, etc., two schools attended by 1,175 scholars; 322 water-closets and 186 pail-closets; the length of the sewers was about 5,560 yds. The area was, in fact, selected because the local conditions made the sewers within it the most difficult to ventilate that could be found in a city where from various circumstances the problems regarding the efficient ventilation of the sewerage system are, perhaps, among the most difficult and complicated in England.

The contractor who had supplied the fan had guaranteed that it would discharge 6,000 cu. ft. of air per minute against a water pressure of an inch, but in actual use only 4,036 cu. ft. per minute was registered. Anemometer tests showed that 247 cu. ft. of air per minute was brought into the sewers through the air inlets, and that four of the inlets at times acted as outlets. The water gauge registered a vacuum of ½ in. in the pipe connecting the sewer with the 20-in. upcast shaft.

This system of ventilation produced a considerable dilution of the sewer air where the connections were good, but only a small proportion was drawn in through the regulated fresh-air inlets that were provided, and this notwithstanding that every care was taken, short of relaying the sewers, to make them air-tight; the system was, however, considered worthy of further investigation. The air escaping from the outlet shaft contained no more bacteria than the street air, and on some occasions much less. It had, however, an unpleasant smell, and it was considered doubtful whether there was any advantage in throwing into the street air at one point large quantities of bad-smelling gases such as escaped from the [illegible] shaft.

Method B consisted of a special type of lamp column erected on the footways or carriageways, and connected with manholes in the centre of the road or direct with the sewers by [illegible] pipes. The pipes used were 6 in. in diameter, enlarged to 9 in. in diameter near the sewer or manhole. The column of the lamp contained a [illegible] diameter [illegible] tube connected at its lower end with a pipe leading to the [illegible] and at the upper end to three incandescent gas burners in the lantern. The lantern was air-tight, with the exception of the outlet fitted immediately over the burners; the sewer air [illegible] by the lamp passed through and round the burners, and was discharged into the street air through the lantern at the top.

The amount of air passing from the manhole through the pipe was generally so small that no [illegible] sufficiently [illegible] when placed in the end of the pipe, [illegible] therefore, the end of the pipe was closed with the exception of the space occupied by the recording instrument, in order to set up a sufficient velocity to enable the instrument to register. A small current of air was thus produced in the 6-in. drain attached to the base of the column, but its effect on the air in even the smaller sewers was practically nil, and quite worthless in the case of large sewers. The average quantity of air extracted per lamp was 723.9 cu. ft. per hour.

The amount of coal gas per lamp consumed from June 20th to September 21st was 33,000 cu. ft., at a cost of £3 14s. 3d. At another site the average amount of air drawn from the sewer by this apparatus was about 1,100 cu. ft. per hour.

Prof. Delepine found no evidence of any material dilution of the air in the sewer even close to the ventilating column. When the lamp was not lighted there was an escape of bad-smelling air, but the number of bacteria reaching the lamp outlet was very small. When the gas was lighted, the smell was not noticeable. The temperature of the air at the outlet was so high (exceeding 250 deg. Cent.), that even during a rapid transit it is believed that the bacteria suspended in the air would be destroyed, and this was proved to be so in the case under investigation. The system appeared to be capable of reducing a local smell nuisance without affecting the state of the air in the sewers, and the action of each lamp appeared to be very limited.

Method C consisted of forcing the sewer air, after admixture with fresh air, by a jet pump through clean water, which was supposed to wash it and free it from all impurities. Complaints were received of smells from one of these washing installations, which it was ascertained did not come from defective covers or any points outside the apparatus. Each ejector installation required about 254,000 gallons of water per quarter if worked continuously. The cost for water at Manchester amounted to about £13 13s. per ventilator per quarter.

The proprietors claimed that the sewers would be kept entirely free from sewer air, but this was not justified by the results obtained. Prof. Delepine found that this apparatus did not materially affect the composition of the air contained in the sewer to which it was applied. The air escaping from the outlets at the level of the pavement usually contained about twice as much carbonic acid as the air collected about 5 ft. above the pavement, and distinctly more carbonic acid than air collected at the level of the pavement; the air also had an unpleasant smell.

Method D consisted of a cylindrical casting containing a cotton-wool filter and disinfectants, and fitted into the manhole shaft, and the inventor claimed that by this method the heat of the sewer air could be made use of to prevent the cotton wool becoming saturated by the condensation of warm, damp sewer air, but the results of the tests would not warrant the general application of the system.

Shortly stated, the investigation of the subject at Manchester showed that the air within the Manchester sewers, situated at a depth exceeding 10 ft. below the surface, generally contained more carbonic acid than the worst street air, and that the proportion of carbonic acid in sewers increases with the depth below the surface, and becomes considerable when all openings are closed, a condition necessary to mechanical ventilation. Although a large quantity of of carbonic acid can be extracted by mechanical ventilation, a greater proportion was found in the air of sewers that were so ventilated, which may be accounted for by the restriction of free ventilation, a condition indispensable under Methods A, B, C, and D.

Prof. Delepine found that the bacteria in the air of the street sewers ventilated in the ordinary way were subject to variations which appear to be due to sudden disturbances of the air, such as steps in sewers, the fall of sewage from inlets above the level of the flow, and condensation on the sewer surfaces exposed to the air.

In order to estimate the influence of sewer air upon health, an elaborate system of experiments has been commenced by Prof. Delepine at the Public Health Laboratory, Manchester, and has not yet been concluded; the results obtained up to the present are, however, extremely interesting and instructive.

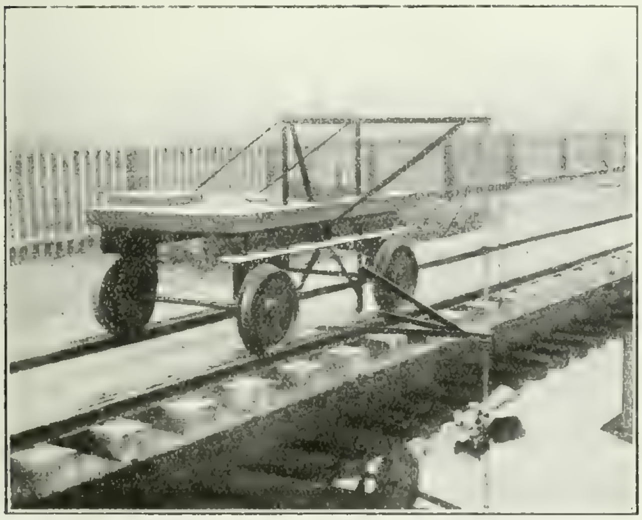
◆

A CURRENT METER RATING STATION.

The current meter rating station at the Irrigation Office, Department of the Interior, Alberta, was described in a paper read by Mr F. H. Peters, Chief Engineer, to the Canadian Society of Civil Engineers, on October 10th. An abstract of the paper follows:—

The work of stream measurements has been carried on by the Irrigation Office, Department of the Interior, for a long period of years in the two Provinces of Alberta and Saskatchewan, but it was not until the early part of 1909 that the great importance of this work was recognized by the Department, and at that time a special Hydrographic Surveys branch was organized under Mr. P. M. Sauder, C.E., from which time the work of stream measurements has been carried on systematically and extensively.

Prior to this time a current meter rating station had been established on a slack water mill pond on Bow River at Calgary, but its equipment was never very satisfactory, and it finally fell into bad repair and its use was discontinued. Along with the formation of the Hydrographic Surveys branch was considered the matter of establishing an up-to-date and efficient current meter rating station, because it was realized that without this equipment, by which means all current meters used could be frequently rated, the current meter records would be liable to serious errors.

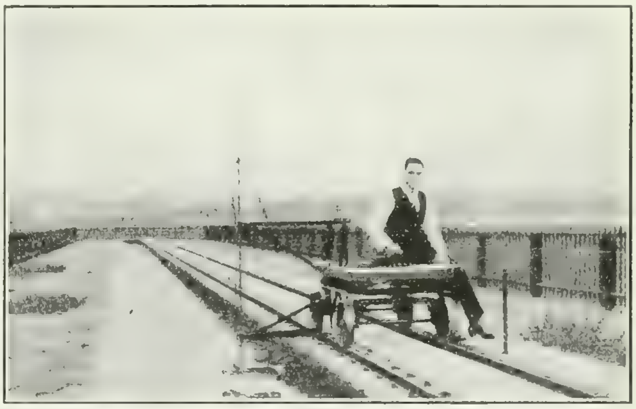


View Showing Meter Suspension Irons.

No active steps were, however, taken in the matter until the winter of 1910, when the plans, speifications and estimate of cost for the station and equipment were prepared by the writer. The contract for the work was let to the firm of Jones, Blackshire & Lyttle, of Calgary, on May 29th, 1911, and was completed by them on July 21st, 1911. In carrying out the construction the steel reinforcing, the steel rails, the cement, and the car were supplied by the Department, and the city of Calgary laid the water supply pipe to the edge of the rating station property. Everything else was included in the contract except some small electrical fittings, which were installed after the work was completed under the writer's supervision. The total cost of the station and equipment was $4,475.39. The total estimated cost for the station was $4,690.24.

In designing the work the aim was to gain the most perfect apparatus possible for rating the current meters and to create a permanent structure, so that it was early decided to use concrete in the construction of the necessary tank.

As no stretch of still water having a suitable length and depth was available, it was necessary to create a tank, and in studying its design two points had to be principally considered. First, as the water supply had to be taken from the city mains the tank had to be made proof against any leakage, as the city authorities were not willing to guarantee any large supply of water such as might be required if any serious leakage from cracks developed in the tank. Secondly, the cross-sectional water area was required as small as possible, and yet of sufficient dimensions to guard against any following-on movement of the water, in running the meters through the tank. To overcome the first difficulty a heavily reinforced structure was designed, such that being emptied and exposed to the weather in winter no temperature cracks could develop, and the inside faces of the tank were waterproofed by Sylvester's process. In deciding on the proper cross-section of the tank to overcome the second difficulty no data were obtainable, but with the tank as constructed no following-on movement or undue disturbance of the water has been observed, even with the largest meters tested at velocities as high as 10 feet per second. The length of the tank (250 feet) was adopted in order to bring the cost of the structure within the limits of the amount of money available, but provision has been made in locating the tank for its future extension to a length of 500 feet, which is desirable in order to attain the highest degree of accuracy.



Meter Rating Car at Rest; Note the Switch Operating Rod Upright at Right and the "Time" Push Switch Opposite, near the Left Wheel.

A description of the station will be given, the various points of which will be made clear by referring to the several plates.

The main feature of the station is a car to which the current meter is attached and carried through the water in the tank at different uniform rates of speed. The three elements, the distance, the time, and the number of revolutions of the meter, are mechanically measured, and from these the velocity of travel of the current meter through the water is related to the revolution per second of the meter, which relation of revolutions to velocity constitutes the rating of the meter.

The concrete tank is 250 feet long with an inside width and depth of 6 feet by 5 feet 6 inches, and the depth of water to be maintained is 5 feet. The floor and walls are

8 inches thick, and are reinforced heavily, longitudinally and transversely, with ½-inch round mild steel rods, in order to absolutely preclude any temperature cracks in the concrete. The concrete was specified a mixture of one part Portland cement to seven parts clean river gravel, to have at least 15 turns in a good machine, and to be placed wet and thoroughly tamped. All the interior faces were thoroughly spaded in order to create a smooth, close-grained surface, to which to apply the Sylvester's wash. All steel rods at joints were overlapped 16 inches, and it was specified that they were to be wired so as to have contact throughout the whole of this length. The tank floor was laid on an 8-inch foundation of large stones overlaid with smaller stones and gravel, in order to provide thorough drainage for any water which might leak through the tank, so that when the tank is emptied in winter and exposed to the weather no heaving might result from any water being lodged under the tank bottom. The soil beneath is of sandy character, which is permeable to water. The water supply is from a 2-inch iron pipe laid from the city mains, and a 6-inch tile drain 224 feet long, fitted with an iron gate-valve at the tank, allows the tank to be emptied at any time into the Bow River. After the tank was completed all the inside faces were treated with two coats of Sylvester's wash. At the time of writing, the tank has been exposed empty to two cold snaps with the thermometer at 30°, and no cracking of the concrete whatsoever has resulted, except a few hair-line cracks near the top of the walls. As regards the waterproofing, two observation shafts were left along the tank sides running down to the foundation, and no leakage whatever was observed during the summer when the tank was full except a slight dampness at the bottom of the side walls. It should be noted that another reason why it was desired to make the tank leak-proof is that it is intended to obtain evaporation records at the tank in future seasons.

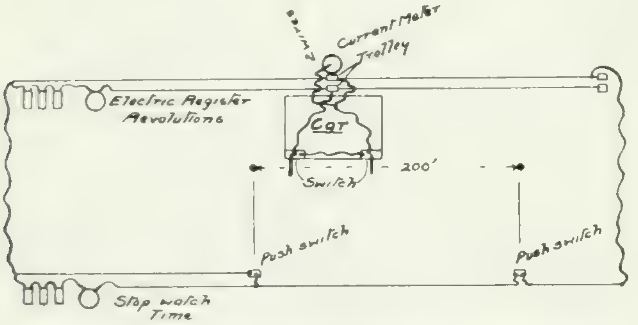


Diagram of Electric Connections

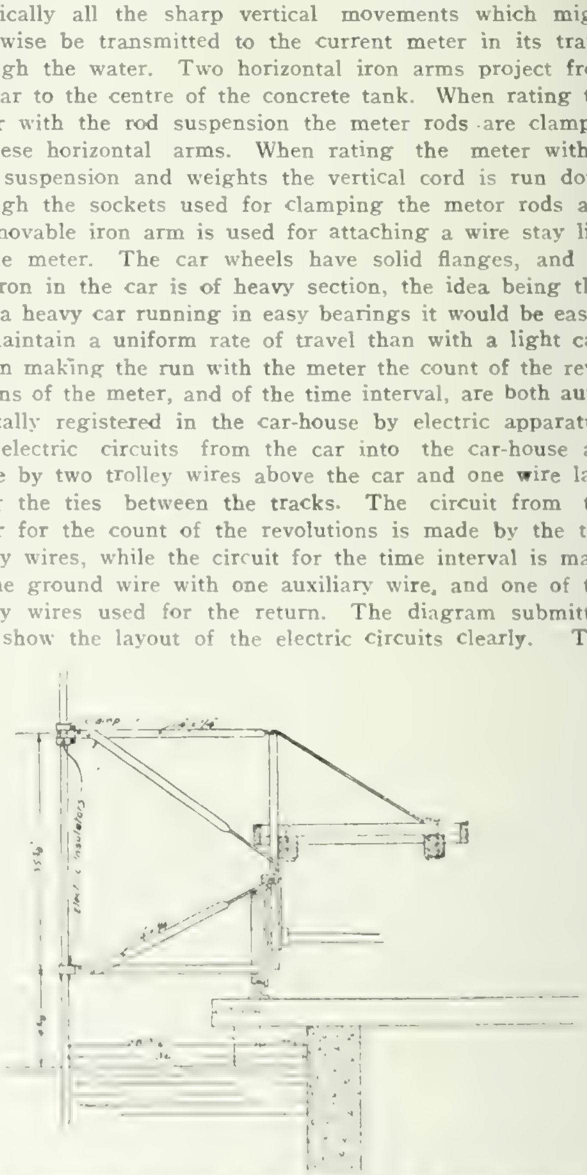
The track laid along side of the tank for the car is of [illegible] rails and laid to a gauge of [illegible] inches on 4 x 6-inch ties, fishplates and bolts being used at every joint. In laying the track, the greatest care was exercised to get it laid solid and as level as possible with close rail joints, in order that the car would run on the track as smoothly as possible. The measured run of the car is 200 feet, [illegible] feet being left at each end of the track in which to speed up the car, and the track passes at one end into the car-house, where the car is kept under lock and key when not in use.

The original idea was that the car should be mechanically driven by an electric motor working on one of the axles of the car. It is [illegible] that the rate of travel of the car over its measured course should be uniform, but after much consideration the writer was not able to devise any method of control by which the rate of travel of the car could be kept uniform (without acceleration) throughout its run, if driven by an electric motor or other mechanical means. The car is, therefore, propelled by hand, but its design is such that an electric motor can be easily attached at any future date if any means can be devised of overcoming the difficulty mentioned above.

The main features in the design of the car have been copied from the car used by the Bureau of Standards, United States Government, at their current meter rating station at Washington, D.C., blue prints of the design of which were very kindly lent by an officer of the Bureau of Standards.

The main features of the car are that the axles run in roller bearings, and the platform is attached to the front axle by a pinion joint, which makes the level of the platform entirely dependent on the rear axle, and thus any tendency of the platform to be twisted due to uneven tracks is overcome. It is thought that this arrangement eliminates practically all the sharp vertical movements which might otherwise be transmitted to the current meter in its travel through the water. Two horizontal iron arms project from the car to the centre of the concrete tank. When rating the meter with the rod suspension the meter rods are clamped in these horizontal arms. When rating the meter with a cord suspension and weights the vertical cord is run down through the sockets used for clamping the metor rods and a removable iron arm is used for attaching a wire stay line to the meter. The car wheels have solid flanges, and all the iron in the car is of heavy section, the idea being that with a heavy car running in easy bearings it would be easier to maintain a uniform rate of travel than with a light car.

In making the run with the meter the count of the revolutions of the meter, and of the time interval, are both automatically registered in the car-house by electric apparatus. The electric circuits from the car into the car-house are made by two trolley wires above the car and one wire laid along the ties between the tracks. The circuit from the meter for the count of the revolutions is made by the two trolley wires, while the circuit for the time interval is made by the ground wire with one auxiliary wire, and one of the trolley wires used for the return. The diagram submitted will show the layout of the electric circuits clearly. The distance over which each run is made is 200 feet, and this distance is marked by two rods set up vertically on the ties at the side of the car. On the car platform are two electric switches with long arms projecting over the edge of the car platform, and these, engaging with the two rods at 200 feet interval, close the electric circuit for this interval, running through the commutator box on the meter, and thus the revolutions of the meter over the interval of 200 feet are transmitted to the car-house, where they are registered by two electric registers set in series in order to check each other on the count. Some difficulty was experienced at first in getting the electric registers to count accurately when

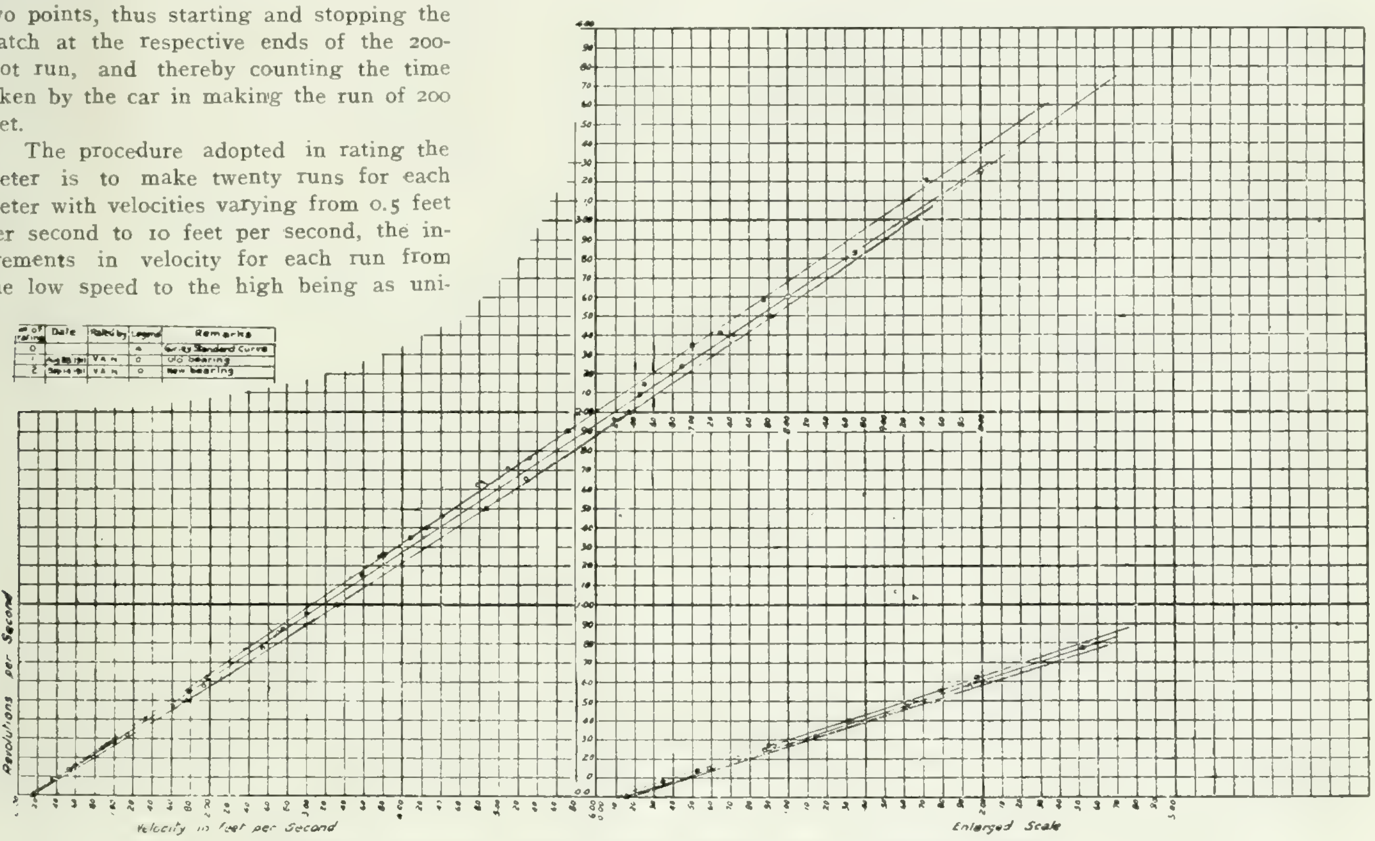


Sketch Showing Method of Suspension of Meter from Car.

running the meters at high velocities, but this difficulty was overcome by always overhauling the commutator box on the meters and making a fine adjustment of the make-and-break apparatus therein. It will be seen that this method of counting the revolutions is liable to be slightly in error, owing to the fact that the registers do not take any count of the fractional revolution of the meter at either end of the run. This error, however, would be reduced to a minimum by increasing the length of the run.

The time interval is counted by a stop watch, which is operated by a simple electro magnet, with a padded lever attachment, designed by the writer, in exactly the same manner that a stop watch is operated by hand. At each rod, marking the 200 foot interval, the circuit running through the stop watch via the two ground wires has inset a one-nipple push switch, and lugs, underneath the car, make and break the circuit as the car passes these two points, thus starting and stopping the watch at the respective ends of the 200-foot run, and thereby counting the time taken by the car in making the run of 200 feet.

The procedure adopted in rating the meter is to make twenty runs for each meter with velocities varying from 0.5 feet per second to 10 feet per second, the increments in velocity for each run from the low speed to the high being as uniformly distributed between the limits as possible. From the data thus gained the revolutions per second with their corresponding velocities per second are computed, the points plotted, and among them the most probable curve is drawn. From the rating curve thus constructed the rating table is prepared for use in the field and office, showing in convenient tabular form the velocities corresponding to the various revolutions per second of the meter, from zero velocity up to 10 feet per second. It should here be noted that the rule in the service is not to measure any stream at a section where the average velocity falls below 0.5 feet per second, and a velocity of 10 feet per second is about the highest met with in practice.



Rating Curve for Gurley's Large Electric Meter, Pattern No. 600.

Showing revolutions per second and velocity in feet per second. NOTE.—This meter was in hard use for two seasons and shows a typical condition of the variance of rating curves. Note that with the old bearing the meter ran fastest, and that the introducing of a new bearing brought the rating curves closer to the standard.

Mathematically, the most probable curve is that drawn from values found from normal equations by the method of least squares. It is considered, however, that the method adopted of taking the values off a curve carefully plotted as noted above is quite accurate enough to meet all practical requirements, and the saving of time and labor by using this method is very great.

For purposes of keeping a graphical office record of the succeeding ratings of the meters a separate sheet is prepared for each meter. On this is first plotted, for purposes of comparison, the standard curve for the meter (Gurley's standard curve for all Price electric meters), and all succeeding ratings of the meter will be plotted on the sheet in different colored inks, with notes as to the date of ratings, conditions of the meter, etc., until the confusion of many curves will require the preparation of a new curve sheet. Revolutions per second are plotted as ordinates to a scale of 4 inches to one revolution per second, and velocities in feet per second are plotted as abscissae to a scale of 4 inches to 2 feet per second. For velocities up to 3 feet per second, an auxiliary curve is drawn with the velocity scale increased to 4 inches to 1 foot per second, to allow for greater precision in taking the quantities off the curve.

It is the intention to carry on extensive experimental work in order to determine the various conditions that affect the rating of the current meter. Especially is it desirable to rate every large meter using the two methods of suspension, that is by meter rods and by cable with stay line. With the limited time available during the past season it was possible to rate the meters only with the rod suspension. Some of the results obtained, however, are surprising and worthy of note. The writer has had a lengthy experience with the use of the Gurley No. 600, large electric meter, and his idea has always been (and he knows that it was shared by other men of experience) that with continued use on account of the pivot bearings constantly wearing, the friction was increased, and the revolution of the meter was thereby retarded. The experience of the past summer in rating nine of these meters has indicated that after considerable use the meters run fast instead of slow. The evidence proves, that with considerable use the bearing points in the meter wear themselves smoother than when received from the makers, and hence have less friction than when they are new. The experiments, however, have not been exhaustive enough to prove anything conclusively beyond the fact that, except when they are perfectly new, no current meter can be relied upon unless it is carefully and frequently rated. The new medium size type of electric meter (Gurley's No. 623) has beeen adopted by this office for the first time this year, and, therefore, no experiments could be made on worn meters of this type. Five meters of this type were tested, of which two had been in light use for one season and three were perfectly new. All of these gave a rating curve practicaly the same as the standard curve issued by Gurley's, but in every case showing the meter running a little faster than Gurley's standard.

Of the small electric meters, Gurley's No. 618, nine were tested, and all showed nearly the same results, although four of them had been in use for two seasons and five of them were new. At low velocities the new curve coincided with Gurley's standard curve, but as the velocities increased the new curve dipped below the standard, which means that the meter was running slower than the standard. This may have been due to the bending at high velocities of the small meter rods by which the meter was suspended from the car. This bending from the vertical of the meter rods was actually noticed to take place, but there was no opportunity to use a stay line to keep the rods vertical, and thereby test the effect of the bending on the rating of the meter. As indicated above, it is the intention to carry on extensive experiments in the future to determine the effect of the method of suspension of the meter on the rating. In practice, all of the large streams are measured by suspending the meter in the stream with a cord and employing a stay line to hold the meter up against the current. Under these conditions, especially with high velocities, there is a tendency for the meter to sway continually from side to side at right angles to the current, and it will be interesting and important to determine what effect this has on the revolutions of the meter. Identical conditions will not be obtainable at the rating station, as the length of the cord suspension will of necessity be much shorter than that used either from a cable car station or from a highway bridge station, and this factor will no doubt enter largely into the [illegible] that the meter will have. Four rating curves are submitted with this paper in order to show graphically actual results obtained in rating meters of different types during the past summer. Explanatory notes have been added (which do not appear on the original office copies), and the curves were selected to show typical cases.

Mr. V. A. Newhall had charge of all the meter ratings during the past season, and under his direction the working parts of the station were put into order and the electric registers and recording apparatus were finally adjusted and improved to overcome difficulties met with in operation. To him, also, the writer is indebted for the notes on the behaviour of the several types of meters on being rated.

In conclusion, the writer would note for the information of members of the Society that the Irrigation Office is prepared to rate any meters that may be sent in by any engineers or others desirous of having their current meters tested and a certified rating table will be prepared and returned with the meters. A small fee, based on the salaries paid to the men by the Department, will be charged to cover only the actual time of the engineer and his assistant employed in making the rating and preparing the table.

[illegible]

CONSTRUCTION OF SURFACES WITH BITUMINOUS MATERIALS.*

By Arthur H. Blanchard, M.Am.Soc.C.E.†

Various kinds of bituminous materials have been used in the United States in the construction of roads and pavements for over fifty years. The introduction of the use of bituminous surfaces and bituminous pavements in the construction of highways outside of built-up districts is af comparatively recent origin in this country, dating practically from 1906. Since that period the growth of the use of asphalts, asphaltic oils and tars has been exceedingly rapid. For example may be cited the increase in the yardage of bituminous surfaces and bituminous pavements constructed with bituminous materials, not including light oils, under the jurisdiction of eight state highway departments of the east. In 1908 the total yardage was 416,700, while in 1911, 17,749,000 yards were constructed. The discussion of this subject will be presented in the form of a brief resumé of typical current practice and a review of some of the causes of failure of the different types of bituminous surfaces and bituminous pavements.

In order to avoid misunderstandings, the various methods of using bituminous materials referred to in this paper will be explained by the following definitions:

Bituminous surfaces are those consisting of superficial coats of bituminous materials with or without the addition of stone or slag chips, gravel, sand or materials of a similar character.

Bituminous macadam pavements are those consisting of broken stone and bituminous materials incorporated together by penetration methods.

Bituminous gravel pavements are those consisting of gravel and bituminous materials incorporated together by penetration methods.

Bituminous concrete pavements are those having a wearing surface composed of stone, gravel, sand, etc., or combinations thereof, and bituminous materials incorporated together by mixing methods.

Bituminous surfaces are usually constructed on macadam or gravel roads, or on bituminous pavements or cement concrete pavements. A notable innovation is the use of bituminous surfaces on brick and wood block pavements. In the case of roads, the mode of procedure is to thoroughly clean the surface by sweeping with hand brooms or horse sweepers or combination of these methods. The bituminous material, which is generally heated, is applied to the surface with the aid of pouring cans, hose attached to gravity tanks, hand-drawn gravity distributors, horse-drawn or power-driven gravity distributors and pressure distributors. After a varying interval, some kind of mineral coating is generally applied to cover the bituminous material.

The causes of failure of bituminous surfaces are numerous. They may be considered from the standpoint of the condition and character of the original surface, the material used, the method of construction or local conditions.

The failure of bituminous surfaces from the standpoint of the character of the original surface is many times due to failure on the part of those in charge to place the surface in satisfactory condition before the application of the bituminous material. Many cases are noted where bituminous materials are applied over a surface in which are found many pot holes and ruts, or which is dirty, due either to

---

[*] Presented before the American Road Congress at Atlantic City on October 4th, 1912.

[†] Professor of Highway Engineering, Columbia University, New York City.

accumulated dust and dirt or to the original method of construction. With certain kinds of materials a damp condition of the surface has resulted in failure.

From the standpoint of the physical and chemical properties of the material, many instances may be cited in which failure is due to materials not having the proper characteristics for the conditions under which they are employed. As an example might be cited the case of a prominent thoroughfare in one of our large cities which is subjected to motor 'bus traffic and a large amount of motor car and horse-drawn vehicle traffic. This road is constructed of gravel upon which has been applied an asphaltic oil and gravel top dressing. The surface at the present time in many sections is full of ruts caused by the traffic pushing the material from side to side. Again, the large percentage of volatile constituents contained in certain asphaltic oils has rendered surfaces constructed with them unsatisfactory because of the long period required for these surfaces to "set up" so that the bituminous material will not track or the carpet thus formed will not creep and form waves and humps. In certain cases the use of light oils on tar or asphalt surfaces has softened the original bituminous surface to such an extent as to render the road or pavement unsatisfactory for use.

From the standpoint of construction, we find failures due both to the use of too small an amount of the bituminous material and an excess of material. Improper application, resulting in uneven distribution, is accountable for many failures of bituminous surfaces, while in other cases a lack of sufficient covering of stone chips or material of a similar character has rendered the surface sticky, mushy, sometimes in the first season, but sometimes not until the second summer.

There are numerous instances where bituminous surfaces have been adopted under conditions which call for the construction of bituminous concrete pavements or even some type of block pavements. A mat type of construction, which has been employed to a considerable extent, has proved inefficacious in cases where horse-drawn vehicle traffic has been more than a certain amount in combination with a motor car traffic which in amount was not sufficient to satisfactorily iron out the calk holes caused by the horse-drawn vehicle traffic. There are cases where esthetics should govern the selection of the type of surface, and generally in such cases the black or brown surface resulting from the use of bituminous material does not harmonize well with the environments.

Bituminous macadam and bituminous gravel pavements are of many types, one of the primary differences in construction being the use of one or two applications of the bituminous material. The efficacy of many of the types depends upon the combinations of sizes of broken stone or gravel and the combinations of bituminous materials used when two applications are employed. Variations in types also exist dependent upon the manner in which the different courses may be filled and the treatment of the filled course prior to the application of the bituminous material. The one application method is very similar in its simplest form to the construction of a bituminous surface except that the bituminous material is applied upon a much more open surface. In the case of the two-application method in certain instances an attempt is made to build up a two-course pavement, while in others the second application is in reality used as a seal coat.

Unfortunately many are the instances where improper bituminous materials have been employed. In some cases the materials were satisfactory in themselves, but were used improperly. Many engineers having charge of bituminous work do not appreciate the cold fact that different types of bituminous materials have entirely different physical properties and require entirely different treatment in use, although they may have been purchased under one and the same specification covering chemical and physical properties. In some cases entirely unjustifiable combinations of materials are employed. For instance, one case is in mind where an asphalt of excellent characteristics was used for the first application, while for the second application an asphaltic oil having decidedly solvent and fluxing properties was employed. Overheating of the material has likewise proved the cause of many failures, as thus the properties of the materials are sometimes changed and in many cases the materials are ruined.

Under the heading construction, we find failures due to the uneven distribution resulting especially from the improper use of hand pouring pots and hand-drawn distributors, and also in many cases when horse-drawn or power-driven distributors are employed. Many unsatisfactory bituminous macadam pavements result from the use of the wrong sizes of broken stone. One instance will be cited where a hard broken stone ranging from 2 to 3½ inches was used for the wearing surface. After rolling, 1½ gallons of bituminous material was applied and the road finished with a layer of chips. The rapid formation of fine cracks, due to the rocking movement of the individual stones under traffic, finally resulting in raveling and general disintegration, is of common occurrence. Segregation of sizes of stone preventing uniform penetration results in weak spots in some cases and "fat" spots in others. In certain cases after a rain the construction has been carried on before the broken stone immediately below the surface has dried out. Many of the causes attributed to the failures of bituminous surfaces may likewise apply to bituminous macadam and bituminous gravel pavements.

Bituminous concrete pavements other than sheet asphalt and pavements laid by companies as proprietary articles have received more attention during the past season than at any time since the days of Abbot, Leverich, Scrimshaw, and Van Camp. Less fear of litigation proceedings and the introduction of economical mixing machines equipped with heating attachments have exerted a marked influence. But, furthermore, the rapidly growing recognition of the inherent advantages of bituminous pavements constructed by the mixing method has been largely instrumental in its adoption for traffic conditions for which it is believed to be economical and suitable.

This type of bituminous pavement is constructed usually by one of three methods. These methods, although overlapping to a certain extent, may be described as follows when broken stone is used as an integral part of the mineral aggregate.

Type A consists of so-called one size crusher run broken stone mixed with bituminous material. It should not be considered that the designation "one size crusher run stone" means an aggregate composed of broken stone of uniform size. This term, as used here, refers to the product obtained at a crushing plant which passes over one size of screen holes and through the next larger, or passes through a screen of one size of holes and is retained upon a screen having smaller holes. It is evident to those familiar with the operation of crushers that the product thus obtained does not usually consist of stone of uniform size. For example, broken stone commercially designated as "three-quarter inch," used in the vicinity of New York City, is obtained in some cases by passing over ½-in. and through 1¼-in. openings. The size of the stone varies from one inch to one-eighth of an inch. It is self evident that this variation in size produces a more stable pavement than if the aggregate consisted of broken stone of uniform size. Type A has been constructed by both hand mixing and machine mixing and by using both unheated and heated stone. Many kinds of bituminous materials have been used, while in some cases one kind of bituminous material has been used in the mix and another kind for the seal coat; one of the most common combinations being the use of tar in the mix and asphalt for the seal coat.

Type B consists of one size crusher run broken stone and sand or other fine mineral matter mixed together with bituminous material. The wearing surface of this mix is sometimes finished by rolling in fine stone chips, but generally a seal coat is used together with fine mineral matter for a top dressing. When constructed on a commercial scale, the mineral aggregate is always heated and mixed in a specially constructed machine. Usually the same grade and type of bituminous material is used for the mix and the seal coat.

Type C consists of a wearing course composed of a graded aggregate of broken stone and sand with or without other mineral matter, which aggregate is mixed after being heated with a bituminous cement in a specially designed machine. As with Type B, this pavement is finished with and without seal coats of bituminous material. The Topeka and the Bitulithic pavements may be cited as examples of Type C.

Having reviewed the fundamentals of the various types, consideration will now be given to causes of failure of some bituminous concrete pavements. It should be noted that the percentage of failures of bituminous concrete pavements is much smaller than in the case of bituminous macadam and bituminous gravel pavements.

Poor and unsuitable materials have been accountable for certain failures. Attachment for a material of a certain type has led to a blind adoption of any material belonging to a given class. For instance, in one case coming under the writer's observation, crude coal tar from one gas works had given good results on the average. Based on this fact, any crude coal tar was finally used, although those in authority had had an object lesson in a failure due to the haphazard purchase of crude coal tar. Experiments in Rhode Island and in the Borough of Queens seem to have demonstrated that high carbon tar of a certain consistency is not as satisfactory or advisable for a seal coat as some types of asphalts, when the percentage and volume of horse-drawn vehicle traffic is large. In some cases an apparent cause of failure has been an excess of flux or of the volatile constituents in asphalt cements. Pavements constructed with such materials many times are wavy, due to the movement of the surface under heavy traffic. Many cases are reported where materials have been overheated at the construction [illegible] may be, and even should be, heated to the same temperature before using and that it is impossible to injure bituminous materials by heating to high temperatures.

During construction there are various details which demand careful supervision. Either too large broken stone or [illegible] this the case with very hard and tough broken stone. The [illegible] which eventually lead to disintegration. Naturally, the amount and character of the traffic is intimately connected [illegible]

unsatisfactory results. In many instances the seal coat has been applied ununiformly. The result is either uneconomical, due to the necessity of a second application before seventy-five per cent. of the surface requires treatment, or the disintegration of the pavement wherever bare spots occur in pavements where a coarse aggregate was used and where there is considerable horse-drawn vehicle traffic. Although of minor import to-day, some failures have been caused by using with unheated stone bituminous cements which will not adhere satisfactorily or which only mix with great difficulty under such conditions.

Many failures are due in both the case of bituminous macadam and bituminous concrete pavements to poor foundations. Sufficient attention has not been paid to this important part of the pavement.

Many of the above causes of failure would be eliminated if engineers would devote more time to a consideration of the physical and chemical properties of the materials which they employ. Records should be at hand covering this data and details of the success or failure of every road noted. If a bituminous material laboratory is not connected with the department, it should not be either expensive or difficult to secure certified analyses made by reputable chemical engineers.

In closing, the writer wishes to emphasize the fact that a careful consideration of the causes of failure of bituminous surfaces and bituminous pavements constructed during the past five years will result in material benefit, inasmuch as a comprehensive knowledge of the various causes of failure is one of the most valuable assets of engineers having in charge the construction and maintenance of bituminous surfaces and bituminous pavements.

◆

AMONG BRITISH COLUMBIA'S MINES.

With a production of 26,683 tons for the third week in September the Granby Company at Grand Forks, B.C., set a new record for smelter treatment in one week and brought the company's total output for the year to 905,782 tons.

Blister copper shipments were also heavy, a total of 523,000 pounds being sent to the refineries. Another Boundary property, the Mother Lode mine of the British Columbia Copper Company, made an unusually heavy shipment, sending 8,201 tons to the smelter at Greenwood, B.C.

Among the silver-lead properties which continued to make the heavy shipments which are one of the striking features of this year's Kootenay and Boundary mining, a new shipper was the Panama near Kaslo which is being operated by Mr. Henry Giegerich and associates.

Work on the tramway at the Rambler-Cariboo mine is making rapid progress and when completed will result in a heavy increase in ore shipments from the property.

Ore production totalled 52,666 tons for the week and 1,764,904 tons for the year to date. Smelter receipts for the week were 47,451 tons and for the year to date, 1,607,190 tons.

Ore production in detail is as follows:—Slocan and Ainsworth production, week 2,472 tons, year 77,373 tons; Boundary production, week 42,332 tons, year 1,445,334 tons; Rossland production, week 5,519 tons, year 174,335 tons; East Kootenay production, week 1,069 tons, year 31,309 tons; Nelson production, week 1,[illegible] tons, year [illegible] tons. Consolidated Company's smelter receipts, Trail, B.C., week 6,755 tons, year 224,918 tons.

British Columbia Copper Company's receipts, Greenwood, B.C., week, 14,013 tons, year 476,490 tons.

Granby smelter receipts, Grand Forks, B.C., week 26,683 tons; year 905,782 tons.

THE PROPOSED WORKS OF THE LONG SAULT DEVELOPMENT COMPANY AND THE ST. LAWRENCE POWER COMPANY.

Our readers will remember that about two years ago there was considerable discussion over the proposed power development at the Long Sault Rapids on the St. Lawrence River. The company who are promoting this development have so far failed to secure a charter on account of the vigorous protests of different Canadian bodies, among them the Commission of Conservation. They have also failed to secure sanction of their project by the Federal authorities of the United States. The St. Lawrence Power Company, Limited, owns the power development at the foot of Sheek Island, near Mill Roches, Ontario. It takes water from the Cornwall Canal, on the north side of Sheek Island, and furnished electric power and light for the Cornwall Canal. The fall in the St. Lawrence River adjacent to the plant of the St. Lawrence Power Company, Limited, would furnish a substantial amount of power. Investigation has shown that without the co-operation of the riparian owners on the opposite American shore, the company can develop this power only to a very slight extent.

The Long Sault Development Company, a New York State corporation, is empowered by its charter to construct dams, power-houses, locks, and other works in the St. Lawrence River, so far as these works will be in American territory. By co-operation and developing the work of the Long Sault rapids, these two companies expect to realize the full potentiality of the river.

Although the project has received two years of strong opposition, still the company continues its campaign to acquire a charter from the Canadian and the United States governments. It is rather expected that the United States charter will be granted this coming session.

The company claims, among other things, that the construction of the works will afford abundant reliable and cheap power to all districts within the radius of transmission of electricity from the power-house; that the furnishing of cheap power will create many new industries, and will be of great advantage to those already established; that the construction of the proposed dams and power-houses will require the expenditure of many millions of dollars, which will be distributed among the transportation companies, manufacturers, tradesmen and workmen, and that the power from the entire development will be used almost exclusively for manufacturing purposes, which will mean increased revenue to the transportation companies, who will distribute these products by boat and rail. It is also stated that navigation will be very much improved; that the South Sault lock will duplicate the means now afforded by the Cornwall Canal for navigation past the Long Sault Rapids, and thus prevent delay due to failure or accident; that the construction of these works will enable boats passing the Long Sault to make a round trip in approximately four and a half hours less time than at present. It might be added that the charter would also allow them to develop a half million horse-power at a very low rate per horse-power.

The above claims of benefits accruing to the country as the result of this proposed development are very interesting, and on their face value, very fine. It must be remembered, however, that at the point where this development is suggested on the Canadian side there are very few industries at the time who would use electric power. How easy it would be for the company, after obtaining their charters, to locate the power-houses on the American side of the river. In fact, the location of the dams, canals and power-houses leads one to believe that practically all of the development will be on the American side of the line; therefore, the expenditure of many millions of dollars on the development will not mean a great deal to Canadian manufacturers. Under present conditions the development of this vast amount of power would not find a ready market for many years in Canada. The outcome of the matter would be this: from power-houses erected on the American side of the line, and developing 500,000 horse-power, the largest available market must be secured. In all probability a great portion of this power would be transmitted to New York city, which is, roughly, 400 miles. This is quite within reason with the present status of electric power transmission.

So far as we can see at the present time there are many reasons why the proposal of this company should be viewed with suspicion from the Canadian standpoint. There are two many chances against an equal division of the results of the development. It is understood that the Commission of Conservation are preparing a report containing a large amount of data dealing with the whole proposition. No doubt no action will be taken by the Dominion government until the whole matter has been carefully investigated. Certainly no such charter should be granted until the government are absolutely sure that Canadian interests are adequately safeguarded.

◆

EXPERIMENTS IN ROAD-MAKING IN SASKATCHEWAN.

One of the elements of most vital importance in the development of any country is its transportation facilities, and the public road is probably the most important of the different means of communication. That we are beginning to appreciate this, more and more, is evidenced by the fact that the Dominion government and the several provincial governments are now lending assistance in the form of grants of money and by the establishment of highway boards to further the good roads movement. A recent communication from Mr. A. J. McPherson, chairman of the Board of Highway Commissioners of Saskatchewan, gives some interesting facts concerning the work being done in that province. Saskatchewan has gone about it in the right way in its initiation of a system of good roads. The provincial government has appointed a highway commission under the chairmanship of a technically trained man with a great deal of practical experience. As a result, they are proceeding along right lines in finding out, first; the type of construction which will be most economical and efficient for the province. To illustrate their methods some of the work of the commission may be instanced. Dr. W. W. Andrews, of the Highway Board, has been engaged for some time past in investigating the practicability of treating the gumbo clays, which are spread so abundantly throughout the province. Quite a large section of the province lying from Weyburn north-west to the Elbow, on the South Saskatchewan River, and north of the South Saskatchewan to the Alberta line, consist of a gumbo clay which does not lend itself to making satisfactory roads. Even an application of gravel or crushed stone is not a success, as the clay is of such a nature that when dry, it is exceedingly hard, and it is practically impossible to prevent [illegible] or [illegible] forming on the road. When wet it turns into a liquid, and in a very short time any coarse material that is put on the road becomes impregnated with this liquid and is lost. Experiments have been made with tannic acid, which, when applied to this clay, will take away some of these qualities, the tannic acid being obtained from ordinary straw or hay by means of a certain process. It is understood that this method has not proved itself up to the present to have a likelihood of success. Dr. Andrews has also devised a method of calcining the clay by means of burning lignite or straw in the form of a kiln on the road. The results from this method seem to show that there is some hope of success. When the clay is calcined in this way it does not form a mud, as it will in its natural state. An experimental piece of road is now being tried on a practical scale with the object of seeing how the resulting products from the calcination process will stand the test. It will also give the Commission an idea of the cost of a unit length of road by this method. The Highway Commission of Saskatchewan are to be congratulated on their enterprise. This Commission is an example of what may be secured when technically trained men are appointed to positions calling for technical knowledge.

◆

UTILIZATION OF PEAT FUEL.

A report on the utilization of peat fuel for the production of power has just been published by the Department of Mines. It is a record of the experiments conducted at the fuel-testing station at Ottawa during 1910 and 1911 by Mr. B. F. Haanel, B.Sc. This report is enthusiastic regarding the result of these experiments. Describing certain alterations made to the peat gas producer and cleaning system, Mr. Haanel says: "The main difficulty, however, still exists, as in the old form of the producer, namely, the formation of a variety of tar; as a thin liquid when condensed, and as finely divided particles carried in a state of suspension after passing through the cleaning system. This objectionable by-product cannot be obviated in the producer itself, but must be separated out mechanically.

In estimating fuel costs Mr. Haanel assumes that peat with a moisture content of 25 per cent. can be delivered to the producer for $2 per ton. "In order, however, to take advantage of this, or a lower cost for fuel, the power plant will have to be situated at or near the bog where the peat fuel is manufactured. For small plants this might not prove feasible in many cases; but will prove entirely feasible and practicable when the plants are of large capacity and when the energy developed is transmitted, in the form of electricity, to neighboring towns and villages, for lighting, power and other purposes.

"Since the fuel burned in the producer does not require to be of the best quality," he continues, "the fuel cost may be considerably reduced, since the broken peat bricks and considerable fines—which always occur in the manufacture of peat, and otherwise represent a loss—can be efficiently utilized in the producer. Assuming, however, that peat can be delivered to the plant for $2 per ton, and that the plant is run with a power factor of 75 per cent. for 3,000 hours, the fuel costs would be $8.30 per B.H.P. year, including standby losses."

No doubt this report is made only after most careful thought and investigation. There have been so many reports during the past fifty years regarding the successful utilization of peat, that reports to-day are received with some measure of reserve. We sincerely hope that Mr. Haanel's predictions will be justified, for the utilization of our peat fields will mean a great deal for the industries of Canada.

DESIGNING BRICK AND STEEL CHIMNEYS.

In designing chimneys the height is generally decided upon first. This involves consideration of the height of surrounding buildings or hills, the length of all horizontal flues necessary, the character of fuel to be used, etc., as well as any local laws or ordinances that may apply. The chimney diameter may then be calculated, based upon the selected height and the boiler horsepower or the amount of fuel to be consumed. In the October 8th issue of Power, Mr. Everard Brown discusses the designing of chimneys and we herewith reproduce the article.

The minimum height necessary, however, will be governed to a great extent by the fuel—wood usually requiring the least and fine anthracite coal the greatest—the character of the installation and the number of furnaces served. Obviously the smaller and more round-about the flues, the higher must be the stack; likewise, a single furnace will require less height than several discharging into a common flue. On account of these variables, it is practically impossible to evolve a general formula applicable to all cases. Except in rare instances, extremely tall chimneys are not necessary and any increased efficiency gained by them hardly ever justifies their greater cost. The tendency is to build two or more smaller ones rather than one high one, which can very often be done at less cost.

A chimney should be proportioned to give sufficient draft for the boiler to develop much more than its commercially rated power, or, according to Kent, to bring about the combustion of 5 lb. of fuel per rated boiler horsepower per hour. By assuming such a liberal rate of combustion, the stack will certainly be large enough. Based on this assumption Kent gives the following equation:

$$E = \frac{0.3\ Hp.}{\sqrt{H}} = A - 0.6\sqrt{A}.$$

where:

E = Effective sectional flue area of stack in square feet;
Hp. = Horsepower of boilers;
H = Height of chimney;
A = Actual sectional flue area of stack in square feet.

The actual is not the effective sectional area because friction retards the ascending gases. The annular stratum of gas retarded by the wall in reality diminishes the flue area.

Molesworth gives:

$$A = \frac{Hp.}{1.28\sqrt{H}} = \frac{C}{12\sqrt{H}}$$

where

C = Pounds of coal consumed per hour.

From this equation, H may be found if the sectional area is known or assumed, or by the same process the horsepower may be found for which an existing stack is sufficient. Sometimes wind-caps are used to increase the stack capacity, but this is only rarely advisable because of their dangerous position.

Stability and wind resistence are next to be considered. Wind pressure is usually assumed to be horizontal and uniformly intense at all levels. Where a chimney is shielded by buildings, only the part actually exposed need be considered. Generally a maximum pressure is assumed of 50 lb. per square foot, although this would require a wind velocity seldom reached. A simple rule for calculating wind pressure is:

The square of the velocity in miles per hour divided by 200 equals the pressure in pounds per square foot.

The total pressure against a round chimney is about one-half that against the diametral plane of that chimney. It is therefore the product of the pressure per square foot by one-half the total projected area of the exposed part. Similarly the total pressure may be calculated for chimneys of almost any form.

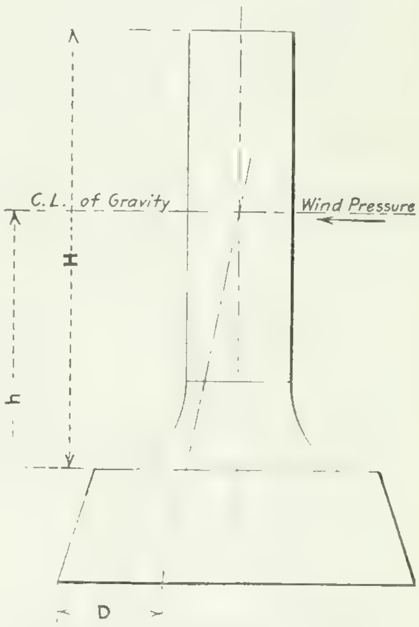
The resultant of this pressure may be assumed to act horizontally through the centre of gravity of the exposed part. The stability of a wholly exposed chimney, therefore, is determined by finding the moment of this pressure acting through the centre of gravity. From the accompanying illustration this moment is

$$h \times P_1 = H \times P \times \frac{A}{2}$$

where

h = Height of the centre of gravity above the top of the foundation;
P_1 = Total pressure exerted;
H = Total height of the stack;
P = Pressure in pounds per square foot;
A = Total vertical sectional area.

For chimneys with vertical axes, the moment of stability is the same in every direction, but few chimneys have exactly vertical axes; therefore, the least moment of stability must be considered as that which opposes the lateral pressure in the direction in which it leans. The stability at any height of a chimney, for example at a certain bed-joint of a brick structure, may be established in the same way by simply considering that part of the chimney above the point at which the stability is to be determined. Opinions differ regarding the strength of brickwork, which, together with the varying qualities of materials and workmanship, makes it exceedingly difficult to accurately calculate the power of resistance. Consequently a large factor of safety is always advisable.



Determining Stability of Chimney.

Fundamentally, a chimney's stability depends upon the weight of its outer shell and the diameter or width of its base, and, while the cohesion of the mortar in a brick stack may add something to its strength it is too uncertain to be relied upon. The effect of the two forces—the weight of the chimney and the pressure of the wind—is to shift the centre of pressure at the base from the axis toward one side, extent depending upon the relative magnitude of the two forces. A comparatively safe rule to follow is to make the base diameter not less than one-tenth of the height. This rule has been approved by many years of actual practice

Steel Chimneys.—Probably the cheapest chimney is a straight steel shell guyed with rods or wires. These are secured to the shell, usually by an encircling band, and should be anchored to incline at an angle of not more than 45 deg. with the ground. Where other structures are convenient the guys may be fastened to them. This type of stack is rapidly being supplanted by the so-called self-sustaining stack. It can be lined or not. Ordinarily when working to full capacity, the high velocity of the ascending gases allows little heat to be lost by radiation even through [illegible] If the gas temperature is [illegible] lining is desirable at least part way up. Firebrick is sometimes used, but probably more often hard-burned red brick that can withstand temperatures up to 750 deg. without injury. This lining should never be less than 4½ in. thick at the top, whether it goes up only part of the full height of the stack and should be thicker toward the bottom by 4½ in. for about every 35 or 40 ft. Not less than 1 in. should be allowed between the shell and the lining with no rigid bond between them, thus making both self-sustaining and allowing for expansion and contraction.

For ease of construction and economy, uniform diameter of the shell for all sections is preferable; the bottom of each section should lap outside the top of the next section below, except for brick-lined structures, when the reverse is often preferred. The rivets in horizontal joints should be double staggered, thus giving more lap for the sheets and, consequently, more stiffness to the shell. Single-riveted joints usually answer for vertical seams. If possible, each section should be made of a single plate, to avoid the extra riveting. In the flaring base both the vertical and the horizontal seams should be double staggered. The cone-shaped base is naturally the strongest, but bases curved like a bell are quite common, and may be equally strong if thicker material is used. Better appearance is the only advantage of the curved base.

Occasionally instead of either cone- or bell-shaped bases, the shell is made perfectly straight down to the foundation and anchored to it by steel braces or cables with turnbuckles. The latter are usually fastened to the stack at a height of about three diameters of the flue and have approximately the same slope as the conical base. This type of construction [illegible]

Caps or other ornaments at or near the top of a steel chimney are no use and a poor investment, but if desired should be of copper to be quite light and rust-proof, and firmly attached to prevent risk of being blown down, causing damage or human injury.

The chief advantages of the self-sustaining steel chimney over all others are less space occupied above the ground, and easier and more rapid construction and erection; and over brick chimneys in particular, lighter weight often saving pile driving in low load-sustaining soils; less area presented to the wind; elimination of air infiltration and consequent checking of the draft; greater strength and safety, and smaller cost. Places and conditions where steel shell construction would not be at all practicable nor economical are, for example, along the sea coast or where acid fumes [illegible]

Brick Chimneys.—The most common brick chimney is [illegible]

[illegible]

ordinary red brick the lengths may be from 25 to 30 ft. with an outside batter of 1 to 30 or 35, or they may increase gradually from the lowest division to the highest. Using bricks of greater crushing strength, these divisions may be made longer. The wall thickness and the batter must conform to the various lengths to insure stability. The former, giving weight to the structure, and the latter, presenting a sort of lever arm, combine to resist wind pressure. Since a swaying motion is usually set up by the wind, it is never desirable to connect the chimney rigidly with any other structure.

[illegible], much depends upon the workmanship and material; both should be of the best. Important, also, is not to erect too rapidly for the mortar to properly set and the foundation should have plenty of time to harden and settle. In several ways the brickwork may be bonded satisfactorily. The most common bond is probably one row of headers for every five rows of stretchers, although alternate rows of headers and stretchers, or two of the latter for one of the former are also used. Often in large chimneys an iron or steel hoop or tee iron is laid within the brick wall every few feet. This is good, especially where the wall thickness exceeds, say, 10 to 12 in.

Concrete Chimneys.—Reinforced-concrete chimneys are least common and were introduced only about 10 years ago. Information regarding them is meagre and they have hardly had time to demonstrate their durability. Ordinarily, they have inner and outer shells with an annular air space between. The shell thickness depends upon height, diameter, etc. The steel reinforcement is usually vertical bars with ends overlapping, spaced according to the size of the chimney. These bars are encircled by steel rings and are extended down into the foundation to insure a good anchorage. They are calculated to resist all pressure by the wind and any tensile strength in the concrete is usually considered an addition to the safety factor.

Foundations.—Logically, the first detail is the foundation and in its design must be considered any local building laws that apply. These laws usually specify the loads allowed in tons per square foot of area for ground of various kinds. Where the soil is very loose or sandy, piling is often necessary, but, regardless of expense, a solid, amply large foundation is imperative. Brick, stone or concrete may be used either individually or collectively. Concrete is commonly used for the subfoundation with brick or large stone above. The area of the foundation should be sufficient to prevent unequal steeling. It will receive greater pressure from above on the leeward side to the prevailing wind, resulting in a canting of the chimney if the foundation is not broad and substantial. The foundation should be such that wind pressure against the chimney will not unduly increase the load on it at any point.

To determine the stability of the chimney in relation to its foundation: first, find the greatest total wind pressure to which the chimney might be subjected and its moment about [illegible] the base of the foundation; second, the total weight of the chimney, including its lining and [illegible] the foundation itself. The former divided by the [illegible] will give the distance from the outer edge of the foundation, or the lever arm of the combined weight of the [illegible]

[illegible] struction and anchorage. In addition some strength will [illegible] Evidently the greater the combined weight of the foundation and chimney [illegible]

SYSTEMATIZING FORM WORK.

Reinforced concrete contractors recognize that the cost of form work is one of the dominant factors in determining whether a given job is executed at a profit or a loss. During the last few years a number of construction companies have been investigating methods of form work with an endeavor to devise some system whereby the cost could be reduced. One of the most successful efforts in this direction has been that of the Aberthaw Construction Company, Boston, who, by detailing the forms in the drafting-room of their home office and by a careful routing of the material, have reduced the cost of their form work 20 per cent. in the last three years. Those who have been in contact with this work have called it "scientific management," but a prominent construction engineer calls it "systematizing," and very aptly puts it: "We pay thinking men to think, and carpenters to saw boards."

Perhaps the very best way to illustrate the system is to consider the question of form work at the ten-story Larkin Terminal at Buffalo, N.Y. This building was erected by the Aberthaw Construction Co., while the consulting engineers were Lockwood, Greene & Co., of Boston. The total quantity of form lumber used was nearly 1,000,000 board feet. In order to understand that which follows it should be noted that this structure is 580 ft. long by 109 ft. wide, the floor space being over fourteen acres, and is bounded by Van Rensselaer, Carrol, Exchange and Hydraulic Streets.

First of all, at the home office a location plan of all beams was made. In this, similar beams were given identical numbers irrespective of location in the building itself. From this location plan form drawings in detail were made, a detail drawing being required for each different sized form, both for sides and bottoms, and the beams of different varieties of column forms were also detailed.

Typical Detail Sheet and Timber Schedule.

The system of lettering used on this work is of particular note. In order to show the exact location of each form in the building, letters were suffixed to the beam numbers. For instance, a form marked BSE18 would mean that it was for the beam side of beam No. 18 on Exchange Street. The bottom form for this same beam would have the symbol BBE18.

An additional number had to be added to the symbol in the case of the column forms, as there is a variation in the height of the floors. The figures prefixed to the ordinary column symbol designated that the particular form was for the second story columns. To illustrate, a column form with symbol 2CSE19 would mean second story form column side Exchange Street, while 19 is the number of column proper as specified by the original location plan.

Form details were designed complete for two stories, and to each form detail was given a symbol to be stenciled on this form when made up, together with the number or quantity required in the first two stories of the structure. On this same form detail the width of the form was divided into an exact number of boards, which were to make up this total width of the dimensions written on the drawing. Therefore, having given the exact length of form and the width of the different boards going to make up this form and the total number of forms required for the job, it is quite readily seen how the sum total of boards, with the exact dimensions, was easily summed up.

Aside from these form details, it was, of course, necessary to draw plans showing assembling of forms, the chief object of this being to specify the spacing of posts and jacks, amount of bracing, and location. From this assembly plan, together with a layout plan of the building, the exact number of pieces and size of lumber constituting the centering could be scheduled. On this completed schedule bids were obtained from the various lumber dealers before ordering the material for the job.

It was very vital that a systematic plan of piling and laying out the lumber should be adopted, inasmuch as 1,000,000 board feet were used. Particular attention was given the dressed stock going to make up the forms proper, since this was taken to and from the mill to the benches. The lumber was so piled that when the laborer wanted a certain number of boards of a particular size he could find them quickly, for a plan was drawn showing the lumber layout and the relative location of different piles of lumber according to widths and lengths. Signs were placed in front of each individual pile, stating the dimensions. On the Larkin job the Aberthaw Company found it best to build two distinct saw mills, since 90 per cent. of the dressed stock had to be cut to exact length. Both mills had practically identical equipment, but were laid out slightly different. The most used piece of machinery in those mills was a cut-off saw, on either side of which was a table, where the stock was placed before being cut. The other equipment consisted of a rip-saw, boring machine, planer, and emery wheel.

To illustrate the methods employed in making up a complete form from the blue print as received from the central office it may be desirable to follow in detail a single operation.

The form details, as previously mentioned, stated exactly the boards which would constitute a particular form and the number of forms required. Cards were made out at the route clerk's office stating for the labor foreman the number of pieces of stock and sizes to be taken to one of the mills. The mill men in return received orders from the route clerk stating the length to cut off the stock, and, if ripping was required, to what width to rip. It was the duty of the labor foreman to tag this stock according to the M number indicated on his order card. When all the stock required for a certain form had been cut and delivered to the proper bench, orders were issued by the route clerk to the two carpenters, who worked at the same bench, to make the number of forms required as indicated on the blue print.

In order that the forms were made up in time to erect as planned by the office, eight benches were used, with two carpenters at each bench. The carpenter having been given his orders by the route clerk, telling him what lumber would be tagged to make up a certain specific form, and having been given blue print of the same form, he merely laid his stock on the bench and nailed it together. When the forms were completed a laborer oiled the same and stenciled them according to the symbols printed on the forms by the carpenters. If not required for immediate use the forms were piled systematically back of the bench at which they were made. When needed, teams carried the forms to that part of the building for which they were designed. Since it was previously determined at which point of the building the erection was to be started, a clerk was given the duty of listing forms as required for erection, and seeing that labor foreman received orders to have these forms delivered to the exact part of the building where and when needed.

CONSTRUCTION OF A WOOD STAVE PIPE.

In discussing a recent paper given before the American Society of Engineering Contractors on the construction of a 48-inch continuous wood stave pipe, Mr. Willard D. Lockwood gave some interesting facts regarding the laying of a 24-inch machine made wooden pipe, five miles in length.

The pipe was made by the A. Wyckoff & Son Company, of Elmira, N.Y., of selected Canadian pine, cut into lengths of 8 to 12 feet. The speaker found it advantageous to use the shorter length, as it permitted piling the pipes crosswise in a box car.

On good ground a foreman and eight men could easily lay 1,000 feet of 24-inch pipe per day. With the cost of $5.50 for the foreman and $1.75 for the men for 9 hours, the cost of laying the 24-inch pipe for four miles across wet meadows was about 4½ cents per lineal foot for labor alone.

The manner in which the pipe was made at the mills is described by the manufacturers as follows:

"The wood from which our wood-stave pipe is made is selected Canadian pine. As the staves are run through the finishing machine, which cuts the double groove and tongue and planes the faces to circular and radial lines, a competent inspector of many years' experience handles every stave just at the time when its defects can best be detected. This inspector culls out about fifteen per cent. of the timber which comes to our factory and these culls are used for other purposes foreign to wood-pipe. The winding machine used for banding the wood staves together is so arranged that the band can be wound at any desired tension, according to the set of the machine, which is regulated for each class of pipe according to diameter and pressure specified. The tension can be made great enough to crush the wood in the large size pipe. During the manufacture of one standard a uniform tension and spacing is absolutely assured.

"The pipes are made in maximum lengths of 12 feet. We have found that sections of 12 feet require a minimum expense in handling at factory, loading and unloading in and from box cars, by which means they are always shipped, hauled to work and placed along the conduit line. The shorter sections permit of the pipes being laid in a curve with perfect satisfaction. As each stave is made, two grooves are cut into one edge ⅛ inch deep and ⅛ inch wide at the base of groove. On the opposite edge two tongues or heads are cut 3/16 inch high and 3/16 inch wide at base of head. Each of these is cut ⅜ inch from the outer and inner face of the stave. When the staves are banded together the head, being a little larger than the groove, is squeezed into it and thus makes a thoroughly water-tight joint. The shorter sections of pipes are always used to make up the curves.

"The coating is heated in tanks by steam to a temperature of between 250 degrees and 300 degrees Fahrenheit and applied to the steel bands as they are being wound around the wood by running them through the tank which stands upon the winding machine; this method insures a full and complete coating between the steel and the surface of the wood, thus preventing the moisture, which may sweep through the outside of the wood, from coming into direct contact with the steel bands.

"After winding, the chambers and tenons are cut on the pipe, each being four inches in depth by one-half the total thickness of the shell of the pipe, which is usually [illegible] inches thick. After leaving the banding machine the pipe is placed on the top of the two grooved rollers, set parallel and horizontal, with one-half their diameters submerged in a tank of the hot Hydrolene. As these rollers revolve, the pipe revolves and its coating which adheres to the rollers is evenly applied to the outside surface of the pipe, covering the bands and wood. After all is applied that the surface will hold, the pipe is rolled on to a table filled with saw dust, the sawdust adheres to the hot coating and protects it from being scraped off or abraded in handling or laying."

COLLECTION AND DISPOSAL OF MUNICIPAL WASTES.

In the monthly bulletin of the Ohio State Board of Health Mr. Irvin S. Osborn, consulting expert in charge of garbage disposal for Columbus, Ohio, makes some comment on the above question. He states that the collection and disposal of municipal waste is one of the most serious problems that confronts nearly every municipality. In the smaller communities it receives little attention without serious results, but as the municipality grows it becomes necessary to adopt some definite plan, by means of which the work can be carried on in a systematic manner.

The experience of the majority of cities has been unsatisfactory. An investigation of the methods employed in cities will show that desired results have not been obtained except in a few cases, indicating that the methods employed are radically wrong in regard to the way the work has been handled. Many cities have expended large amounts trying to obtain better results, both as to the sanitary conditions and also as to cost, but have failed, because as a rule they have either acted on the recommendation of manufacturers of equipment, who make impossible guarantees, or they have copied the method used in some other city where the conditions are radically different.

The work has not been taken up as a problem to be solved, but has been considered as a condition to be overcome in the easiest manner. In other words, sufficient study has not been made of the conditions that affect the problems, and the result has been the adoption of methods that were not suited to the conditions as they really existed. These conditions must be known in advance and the work planned in accordance with them. Many municipalities have adopted some plan, only to find that after all they are no better off than they were before, except that they have gained considerable experience at a large cost.

The engineering and municipal publications have published many articles giving results obtained in various cities and detail descriptions of the various plants for the disposition of wastes. The data and descriptions are of great aid from an educational standpoint for officials who are obtaining enlightenment on the subject, but on comparison they will be found of little value in determining what will apply to the local conditions. The articles are oftentimes written by men who are interested in some special method of disposal or for advertising purposes, so that the opinions expressed are oftentimes biased. The reports or data given on the operation of various plants are oftentimes misleading in regard to the cost for conducting the work, since many items are omitted. This also applies to the estimated value of the returns from the sale of by-products of a reduction plant, or the value of the power that can be developed if disposal is made by burning. The problem must be considered from the standpoint of actual values that can be obtained under the conditions to be met, and not on theoretical values based on what would be the results with ideal conditions. To determine what results can be obtained information should be such that the official can show what the actual results would be.

The collection and disposal of municipal waste is an engineering problem, and only when the municipalities take it up as such, will the advance be made and a desirable solution obtained. At the present time there is no branch of municipal service where the need of study and expert advice is as great as in connection with the collection and disposal of municipal waste. Other branches of municipal service have received the study required and definite information concerning them collected from long experience, but it is only during the past few years that this branch of the service is being recognized as important. Modern methods for disposing of municipal wastes involve problems in civil and mechanical engineering which must be solved in a sanitary and economical manner. If the waste is to be burned, the engineer must understand the combustion of the material to be disposed of and the results that can be obtained in the development of power. Experience shows that all furnaces will not dispose of various classes of waste in either a sanitary or economical manner. If garbage is to be utilized or disposed of by the reduction method, the need of engineering advice is still more essential in order to obtain results that will be satisfactory.

The following will outline briefly a few items that must be considered in studying the problem to arrive at a conclusion that will warrant the adoption of any particular method or a combination of the different methods:—

1. The topography of the city studied to determine the type of wagons and location of central stations or disposal plants, to determine what bearing it will have on the collection of the material from the standpoint of economy and efficient service.

2. The character of the population studied in regard to classes and nationalities to determine the quantity and quality of the various classes of waste as produced in different sections of the city.

3. The plan of the city and character of the residences should be studied with reference to the number of houses to be served and the access to the same in making collections.

4. The production of each class of waste should be studied with reference to the average daily quantities. The monthly variation of each class to determine the maximum and minimum quantities to be disposed of. This is one of the most important determinations to be made. Estimates are often made, taking the average for monthly collections from the total yearly amounts without reference to seasonal fluctuation. Garbage during the maximum months will increase more than 100 per cent. over the average collection during the minimum months, and the combustible waste will often decrease 75 per cent. during the same period, with the result that there is not a sufficient material of combustible nature to destroy the garbage without using additional fuel.

5. Records of the quantities of each class of waste should be obtained over as long a period as possible to determine the relative increase and provide for future growth.

6. What service is to be rendered to residences and places of business.

7. Analysis of all classes of waste from a mechanical standpoint, as well as chemical analysis to determine the value of the various classes in respect to calorific value, water, ash, volatile matter, etc., and when utilized determination as to available grease and tankage and value of the same.

8. The past practice should be studied to determine the work that will be required to systematize the future developments.

9. Estimates of the first cost that would be necessary to adopt each method of disposal. Estimated annual cost for operation, maintenance and fixed charges for each method to determine the most economical method that can be adopted. The estimates will vary with local conditions, quantity and quality of the wastes to be handled.

After making a complete study the question is to determine what method is best suited for the conditions to be met from a sanitary standpoint with proper allowance made for the annual charge for maintaining and conducting the work. It is not a theoretical, but a practical problem to be solved, and can only be solved by obtaining the proper knowledge and experience necessary to decide what is suitable. The correct solution cannot be obtained by trying to copy what some other city has or by what is claimed for various methods. It must be studied with all the information possible obtained, and then applied to the problem to be solved in a practical manner from a sanitary and economical standpoint.

ECONOMICS OF POWER TRANSMISSION LINES.

The following is an article by Mr. Alfred Still, engineer at the Magpie mine, Michipicoten District, Ontario, which was printed in a recent issue of Western Egnineering. It will be remembered that we published an article by Mr. Still entitled "Steel Towers for Overhead Transmission Lines" in our issue of October 10th, 1912.

"True engineering is based on economics." These are the words of R. D. Mershon; and every engineer does or should realize the truth of the statement. On the other hand, there are many engineering undertakings, or portions of such undertakings, in which this fundamental principle has been disregarded. In the case of transmission lines a certain system, or an exceptionally high pressure may have been adopted because of its peculiar interest as an engineering problem; or duplicate lines, spare generating plant, and costly automatic gear may have been installed to ensure continuity of supply, apart from the economic value of such increased protection against possible interruption. This, however, is not engineering in the commercial sense. The determination of the economical size of conductors for the transmission of any particular amount of current. in accordance with the principle generally known as Kelvin's law, is now well understood; but this is a very small part of the problem to be solved by the transmission line engineer. An attempt will be made in this article to deal with the economics of the overhead power transmission line from a broad practical standpoint. Some approximate figures for use in getting out preliminary estimates will be given, and in the working out of any numerical examples it will be assumed that the principles governing the selection of the most economic size of conductor require no explanation. When considering any scheme of power transmission from a generating plant of limited output, it is important to bear in mind that it does not pay to cover distance greater than that within which there are reasonable prospects of supplying all the power available at the generating station. The importance of this principle should be fairly obvious; yet there are instances which prove that it has been disregarded.

Choice of System.—On this continent it is usual to trans- [illegible] not meet with equal success on this continent; but it is [illegible]

Type of Transmission Line [illegible]

used on any particular transmission scheme. In some cases a composite line including two or more types of support may be found advantageous. Among the factors influencing the choice of the supporting structures may be mentioned the character of the country, the means and facilities of transport, climatic conditions, the nature of the soil, and the scarcity or otherwise of suitable timber in the district through which the line will pass. In undulating or hilly country, advantage may frequently be taken of the heights, by erecting upon them comparatively low and cheap structures and spanning the depressions or valleys without any intermediate supports. The engineering features must, however, be very carefully studied in all such exceptional cases.

Length of Span.—Even when the type of structure has been decided upon, the height, strength, and cost of the structures will be dependeent upon the distance between them. The determination of the average length of span is indeed a very important economic question. The material of the conductor will, to some extent, influence the choice of span length, because aluminum conductors will usually have a greater summer sag than copper conductors, and this will necessitate higher supports to give the same clearance above ground at the lowest point of the span. In considering span length, the first cost of the individual support is not the only question which has to be taken into account; the cost of maintenance is almost equally important. The longer the span, the fewer will be the points of support; and if the line is well designed and constructed, there should be less trouble through faults at insulators. Again, when rent has to be paid for poles placed on private property, it is generally the rent per pole apart from the size of pole which has to be considered, and this is another factor in the determination of the best length of span. In level country, the economic span for steel tower construction is usually in the neighborhood of 550 ft. If substantial, braced, wooden towers of considerable height are used in a district where such structures can readily be constructed, the economic span would probably be greater than 600 ft. It is hardly necessary to mention that, when comparing costs of various kinds of supports, the relative life and cost of upkeep of the poles or towers must be taken into account.

Effect of Span Variations on Cost of Steel Towers.—The [illegible] country depends on (1) the minimum clearance between the lowest conductor and ground when the sag is greatest; (2) the voltage, since this has an effect on the spacing of the conductors and also to some extent on the clearance above ground level; and (3) the [illegible]. This last is determined by the lengths of span, the material and size of the conductors, the range of temperatures, and weather conditions generally. For the [illegible]

[illegible]

[illegible]

the height, but also upon the stresses which the tower has to withstand. These again will be dependent upon the size of the wires, the length of span, and the weather conditions. It is probable that, with an increase in height the cost increases less rapidly than the square of the overall length, but for approximate calculations it is convenient to assume the relation cost varies as H^2. Also, if the weight of a tower measuring 60 ft. overall is taken at 1,800 lb., and the price per pound of the finished (galvanized) tower at 5c.,* the cost per tower in dollars is

$$\frac{H^2}{40}. \qquad (2)$$

The cost of the flexible type of tower is appreciably less, being about seven-tenths of the cost of the rigid type with square base, or

$$\frac{H^2}{57}. \qquad (3)$$

It is, however, usual to provide rigid strain towers in place of the flexible type at, say, every mile, and as the cost of such structures is about double the cost of the flexible tower, the cost of supports per mile of line may be calculated by assuming $n + 1$ flexible structure per mile, when the actual spacing is n to the mile.

Duplicate Lines.—A point of great importance in connection with power transmission undertaking is the means adopted to guard against interruption of supply. If it is allowed that the least reliable part of a transmission system is the line itself, it is certainly advisable, when circumstances permit, to duplicate the lines; the two sets of conductors being connected in parallel under normal conditions. The best protection against interruption would be afforded by carrying the two sets of conductors on separate poles, preferably by different routes; but this would almost double the cost of the line, and it is usual to carry duplicate lines either on one set of poles, or on two sets of poles erected side by side on the same right-of-way. As an alternative to the duplication of the lines, the provision of reserve generating plant at the receiving end may be considered, and a comparison should be made between the relative advantages and costs of the various alternatives.

A good example of steam-driven auxiliary plant in connection with hydro-electric power stations, is the recently completed oil-burning steam-generating station of the Southern California Edison Co., situated 25 miles from the city of Los Angeles and capable of connecting in parallel with the 60,000-volt and 30,000-volt systems ordinarily supplied by the Kern River and other hydro-electric generating stations of this company.

Costs of Typical Transmission Lines.—It would be possible to give a large number of figures relating to material and labor costs of completed transmission lines; but the conditions of transport of materials and quality of labor differ widely, and without complete knowledge of these conditions, such figures are liable to be misleading. For this reason two ideal preliminary estimates, one referring to a wood pole line, and the other to a steel line, are here reproduced, in the hope that they may be useful as a basis on which somewhat similar estimates may be shaped.

Preliminary Estimate No. 1.—Wood pole transmission line, 20 miles long, carrying one three-phase line. Line pressure 22,000 volts. Span 130 ft. There is no grounded overhead guard wire; but two telephone wires are carried on the same set of poles. An allowance of 20 per cent. is made for extra insulators and fixtures to permit of doubling these on corner poles and in other selected positions.

Preliminary Estimate No. 1.

MATERIALS (EXCLUDING CONDUCTORS)		
40 creosoted cedar poles, 35 ft. long, 8 in. diam. at top	$400.00	
48 cross arms, 3½ by 4½ in. by 4 ft. long	14.50	
96 galvanized iron braces, 1¼ by ¼ by 28 in. long	9.00	
32 galvanized bolts, ⅝ by 12½ in., with washers 8 galvanized bolts, ⅝ by 16 in., with washers 16 galvanized spacing rods, ¾ by 16 in., with nuts and washers 48 galvanized lag screws, ½ by 3½ in. 96 galvanized carriage bolts, ⅜ by 4½ in.	7.50	
1500 ft. galvanized 7 strand 5/16 in. guy wire	12.00	
12 anchor rods with nuts and washers and necessary timber for anchor logs	7.00	
24 galvanized guy clamps with bolts	3.00	
8 galvanized sheet-iron bands to prevent cutting of poles by guy wire	0.50	
12 standard thimbles for guy wire	0.40	
20 galvanized-iron lightning conductors, with bolts	5.50	
20 ground plates or galvanized-iron pipes	8.00	
Staples and sundries, including allowance for breakages and contingencies	15.00	
80 telephone wire insulators (glass) 80 side brackets for same (wood); 5-in. wire nails	10.00	
144 H.T. porcelain insulators	36.00	
96 galvanized-iron insulator pins with porcelain bases	14.40	
48 special pole-top insulator pins, with bolts	19.20	
Total material cost per mile of line		$562.00
LABOR		
Clearing 50 ft. on each side of pole line @ $30 per acre	363.00	
Distributing poles and other materials along the line	30.00	
Trimming poles, cutting gains, drilling holes, setting cross-arms	30.00	
Digging holes and erecting poles, including the necessary guying	80.00	
Fixing insulators and stringing wires, including telephone line	90.00	
Supervision and sundry small labor items	30.00	
Loss and depreciation of tools	10.00	
Management and preliminary work	25.00	
Total cost per mile for charges other than materials		$658.00
Total cost per mile, excluding cost of conductor material		$1220.00
CONDUCTORS		
16,000 ft. No. 1 copper conductors (hard-drawn); 700 ft. No. 4 copper for ties (soft); 10,800 ft. No. 10 copper for telephone circuit; 4550 lb. @ $15 per 100 lb.		682.50
Total cost of finished line		$1902.50

Preliminary Estimate No. 2.—"Flexible" type steel tower line, 60 miles long, with two sets of three-phase conductors. Line pressure = 80,000 volts. Average span, 480 ft. Spacing between wires, 8½ ft. A Siemens-Martin steel cable, acting as grounded guard wire, joins the tops of all towers. Insulators of the suspension type. No telephone wires. Minimum clearance between lowest H.T. conductor and ground = 40 ft. Cost of right-of-way not included in estimate.

Preliminary Estimate No. 2.

MATERIALS (EXCLUDING CONDUCTORS)		
10 flexible type galvanized steel, A frame towers @ $85	$850.00	
1 galvanized steel strain tower	170.00	
concrete foundations where necessary	80.00	
5600 ft. 7/16 in. galvanized Siemens-Martin steel-strand cable for guard wire and head guys on half mile flexible towers	128.00	
4 anchor rods complete with clamps and thimbles for guy wire	4.00	
90 sets of suspension-type insulators, including strain insulators and small allowance for breakages, complete with clamps	338.00	
Sundry small items or special material	50.00	
Total material cost per mile of line		$1620.00
LABOR		
Clearing 60 ft. on each side of line at average cost of $25 per acre	$[illegible]	
Distributing towers and other materials along the line	100.00	
Foundations for towers	[illegible]	
Assembly of parts and erection of towers	160.00	
Fixing insulators and stringing wires	170.00	
Supervision and sundry small labor items	30.00	
Allowance for loss and depreciation of tools	[illegible]	
Allowance for management and preliminary work	[illegible]	
Total charges other than materials per mile		[illegible]
Total cost per mile not including conductor material		$[illegible]
CONDUCTORS		
No. 00, hard drawn, stranded copper conductors; small amount of No. 2 soft copper for occasional ties, special clamps, shields, jointing materials, etc., 13,350 lb. @ $15 per 100 lb.		[illegible]
Total cost per mile of finished line not including right of way		$[illegible]

The cost of insulators increases rapidly with the rise of the working voltage. The curve of Fig. 1 gives approximate average prices of insulators complete with pins or suspension links for pressures up to 100,000 volts. The prices are per insulator or per series of insulator units. The suspension type of insulator consisting of a number of units in series is almost universally used for pressures exceeding 60,000 volts. One golden rule which applies to all overhead transmissions is that it is false economy to reduce first cost by putting in cheap and possibly unreliable insulators. The curves of Fig. 2 are intended to supplement the figures of the typical estimates. They give approximate costs of transmission poles or towers, with and without in sulators fixed in position. These costs are the averages of many actual figures, and give an approximate idea of the total expenditure per mile of line for various voltages; they do not include any clearing that may be necessary in wooded country, or payments for right-of-way. It is assumed that the conductors are of average size (No. 000 B and S gauge), but the actual cost of the conductors, whatever the size, must be added to the costs indicated by the dotted curves B and D in order to arrive at the total cost of the finished line. These dotted curves, however, do include an amount to cover the labor of stringing the wires. The curves A and B refer to wood poles or rigid steel towers (for the higher voltages) carrying three conductors; while curves C and D refer to a single set of poles or towers carrying six conductors. The cost of a line with flexible steel structures for voltages above 44,000 might be about 75 per cent. of the costs given by curves A and C. It is understood that the curves of Fig. 2 give only an approximate indication of the probable capital expenditure on the line. The actual cost will depend upon the character of the country, the nature of the ground, and other local conditions such as cost of labor and facilities for transportation. These, together with the weather conditions, force of wind and possible loading of wires with sleet or ice, will determine the most economical span and the average height of pole or tower. The cost, as previously mentioned, will also depend upon the material of the conductors, as a larger or smaller sag will influence spans and height of poles. The weight and diameter of conductors, by affecting the required strength of the supports, will be factors in determining the cost of the complete line, apart from any difference in the value of the conductors themselves. The actual cost of stringing very light or very heavy conductors will also differ from the average amount allowed for the purpose of plotting the curves. The number and style of lightning conductors, if any, and whether or not one or more grounded guard wires are strung above the conductors will obviously modify the average figures. Although steel or concrete poles, or steel towers, will generally be found more economical than a wood pole

---

*This cost may be anywhere between 3c. and 6c. per pound.

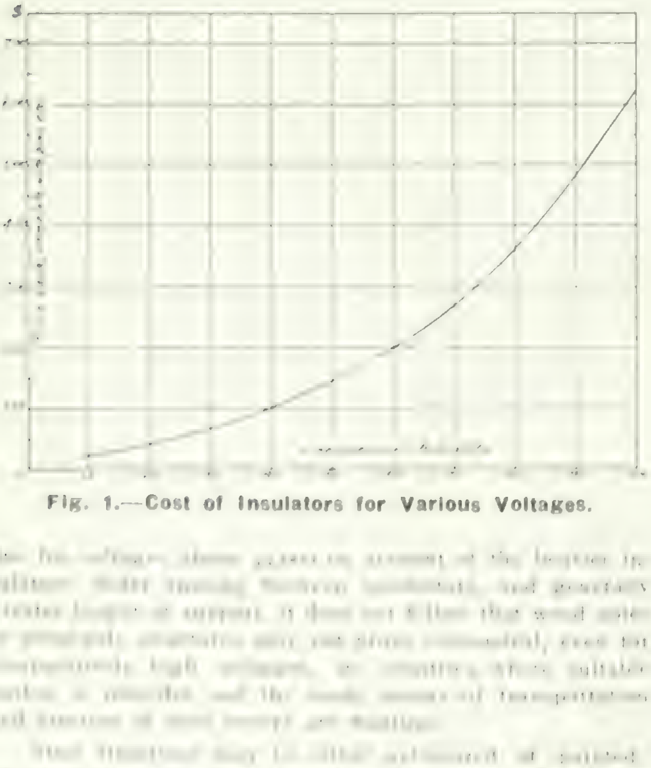

Fig. 1.—Cost of Insulators for Various Voltages.

line for voltages above [illegible] on account of the [illegible] in voltages [illegible] spacing between conductors, and greater height of support, it does not follow that wood poles [illegible] commercial, even for comparatively high voltages, in countries where suitable timber is plentiful and the [illegible] means of transportation and erection of steel towers are lacking.

Steel structures may be either galvanized or painted; [illegible] cost of galvanizing should be compared with the [illegible] cost of painting periodically [illegible]. The cost of [illegible] will usually be between [illegible] and 80c. per 100 lb. weight. A pole 35 ft. high of square section 6 by 6 in. at top and 12 by 12 in. at bottom would weigh about 2,000 pounds.

The cost of foundations for towers varies greatly. In the case of fairly high steel towers with wide square bases in soil not requiring the use of concrete, the cost of excavating, setting legs, and back filling, not including erection of towers, will generally be between $10 and $20 per tower.

Cost of Conductors.—The capital expenditure on conductors will depend upon the material and the total weight. It is not proposed to discuss, in this article, the relative merits of copper and aluminum as conductor materials, but it may be well to point out that although, at the present market values of these metals, the use of aluminum may lead to some saving on first cost, there are many engineering points to be most carefully considered before definitely adopting either metal. The weight of the conductors necessary to transmit a certain amount of power over a definite distance will obviously depend upon the voltage, but apart from the engineering difficulties encountered at the higher voltages, there are economic considerations which determine the maximum voltage suitable for any given conditions. Among these may be mentioned a possible increase in the cost of generating plant for the higher pressures, the greater cost of step-up and step-down transformers and of the control apparatus, together with the line insulators, entering bushings, etc. The transmission line poles or towers will also, as previously mentioned, cost more for the higher pressures, because of the wider spacing between conductors. Then again, with the extra high pressures, the increased losses through leakage over insulators and possible corona losses may be quite appreciable.

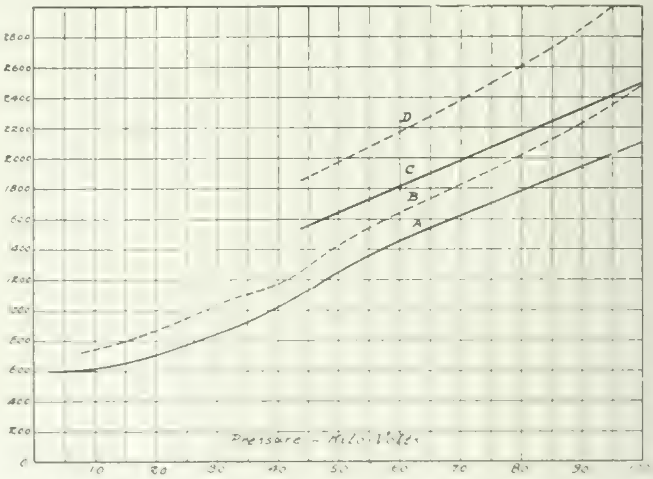

Fig. 2.—Cost in Dollars Per Mile of Transmission Line Complete, Not Including Cost of Conductors, Right-of-Way, and Clearing Ground in Wooded Country.

A—Single 3-phase line without insulators or wires.
B—Ditto, including insulators and stringing but not cost of wires.
C—Same as A, but for double 3-phase line on single set of poles or towers.
D—Ditto, but including insulators and labor stringing wires but not cost of wires.

Given a definite amount of power to be transmitted, and a definite line pressure, the current can be calculated, and the economic conductor cross-section, and therefore the weight and cost of the conductors, will be directly proportional to this current. It is only of recent years that this fact appears to have been generally recognized, and yet, so long ago as 1885, in his Cantor lectures delivered in London, George Forbes said: "The most economical section of conductor is independent of e.m.f. and distance, and is proportional to the current." The determination of the current value to be used in the calculation of conductor sections is a real difficulty. It must not be supposed that even a knowledge of the load factor is sufficient by itself. The load factor being the ratio of average load to maximum load, does not give the relation between the average I^2R loss and the I^2R loss of maximum output. The power lost in the conductors of a constant potential supply is proportional to the square of the power transmitted. On the basis of the average hydro-electric load curve, if the load factor is 50 per cent., the load on which the average transmission line losses should be based, being the square root of the mean of the square of the power, will probably be found to be more nearly 60 per cent. than 50 per cent. of the maximum load.

Economic Voltage.—Clearly, the choice of the transmission voltage is a very important matter; but as it is possible to determine the proper voltage on purely economic grounds, the use of exceptionally high pressures merely because of their interest from an engineering point of view, should be discouraged. On the other hand, it would appear that most transmission line troubles occur on lines working at pressures between 30,000 and 80,000 volts; and an important consideration to bear in mind is that more trouble may be experienced with heavy currents than with high voltages, owing to the more serious effects of interruptions or transient disturbances when the current is large, so that greater security may sometimes be obtained by increasing the voltage with a view to reducing maintenance and operating costs. A remarkable instance of high pressure being used for short-distance transmission occurs in Germany at Lauchammer. This is the first 110,000-volt installation in Europe. The line is only 35 miles long, but the power to be transmitted is considerable, being 20,000 kw. The engineers claim that, owing to large fluctuations expected through rolling-mill load, low voltages would be uneconomical. Under ordinary circumstances, the trend of modern practice would indicate something above 60,000 volts as the best pressure in this case; but when there is little difference between the cost of a 60,000-volt and an 80,000-volt scheme, it is wise to adopt the higher pressure.

When figuring on the best voltage for any particular scheme, the capital cost of all works, buildings, or apparatus which is liable to be influenced by the transmission-line pressure, together with all operating and maintenance charges which may be similarly influenced, must be taken into account. It will usually be found convenient to reduce all such costs or differences of cost to the basis of annual charges.

Costs Other Than Transmission Line, Liable to be Influenced by Voltage Variations.—The cost of a generating station complete with all plant and machinery, but not including transmission line, may be anything from $20 to $200 per horsepower installed. It will depend on total output, that is, on the size of the station, on location, and transport and labor facilities. The cost of a hydro-electric station will depend on the head of water, the amount of rock excavation, the size of dam, etc.

Approximate costs per kilowatt of medium head hydro-electric power station and sub-station (not including transmission line) for total output of about 10,000 kilowatt appear below.

The figures given in the accompanying table are approximate costs for a medium head hydro-electric development suitable for a total output in the neighborhood of 10,000 kw., to be transmitted over two outgoing 3-phase feeders. The usefulness of these figures lies mainly in the indication they give of the probable differences in cost with the variation of transmission-line pressure.

	Transmission Line Voltage		
	[illegible]	60,000	100,000
Hydraulic works outside power station buildings	$15.00	$15.00	$15.00
Power-station building, including excavations	5.00	5.06	5.10
Receiving-station building	1.00	1.03	1.05
Switch gear (both ends)	1.20	1.35	1.70
Electrolytic lightning arresters	0.34	0.66	1.20
Transformers (both ends)	2.50	2.90	3.50
Generaters and exciters	8.00	8.00	8.00
Cables in buildings, entering, bushings, etc.	0.40	0.40	0.50
Crane, sundries, and accessories, including preliminary work	2.00	2.10	2.20
Turbines and hydraulic equipment	10.00	10.00	10.00
Total cost per kilowatt	$45.44	$46.50	$48.25

Annual Charges Depending on Voltage.—These charges may be summarized as follows:

1. A percentage on all capital expenditure, whether for generating station, transmission line, or receiving stations, which is not constant irrespective of voltage.

2. The yearly cost of the power lost in the transmission line.

3. The yearly cost of power lost in generators and transformers (the efficiency of the electrical plant will not necessarily be the same for all voltages).

4. The yearly cost of maintenance and operation. This may depend upon length of spans in transmission line, and on the necessary plant, switch-gear, etc., to be attended to, and kept in working order.

The percentages referred to under item (1) must include interest on capital invested, and depreciation. The accompanying table gives the percentage to allow for depreciation for various terms of years. Depreciation, which may include what is sometimes referred to as obsolescence, is the amount to be set aside annually in order to reproduce, at the end of a term of years, the capital originally invested. This term of years in the "life" of the works or materials on which the percentage depreciation is to be calculated. It is assumed that, at the end of this term of years, the value of such works or materials is nil. It is also assumed that the amount put aside annually earns interest at the rate of 5 per cent. compound.

Depreciation Table.

(On basis of 5 per cent. compound interest earned by money put aside annually.)

Life. (yr.)	Depreciation. (%)	Life. (yr.)	Depreciation. (%)
2	48.70	28	1.710
4	23.20	30	1.505
6	14.70	32	1.325
8	10.50	34	1.175
10	7.95	36	1.045
12	6.28	38	0.928
14	5.10	40	0.828
16	4.23	42	0.740
18	3.55	44	0.662
20	3.03	46	0.593
22	2.60	48	0.532
24	2.25	50	0.477
26	1.96		

Method of Determining Most Economical Voltage.—Consider the case of a typical medium head hydro-electric power station:

Distance of transmission = 50 miles.

Duplicate three-phase line with copper conductors.

Cost of conductors = $15 per 100 pounds.

Power demanded = 15,000 h.p. or 11,200 kw. (It is assumed that this power will be required continuously day and night for industrial purposes, and that it is the probable limit of the water-power available).

Power factor = 0.8.

Selling price of power = $21 per horse-power-year.

Interest on capital invested, allow 6 per cent.

The economic drop of voltage per mile of single conductor is given by the formula:[1]

$$e_r = 8.1\sqrt{\frac{a \times p}{p_1}}$$

Where p is the price in dollars of 100 lb. weight of conductor (in this example $p = 15$), a is the percentage to cover annual depreciation and interest on cost of conductors, and p_1 is the cost per horse-power-year of the wasted power. The proper value for a may be arrived at by estimating the term of years corresponding to the life of the conductors, at the end of which they are supposed to be of no value. Taking 20 years as the life of the conductors the depreciation to be allowed according to the table herewith is 3.03, which makes $a = 6 + 3.03$, or, say, 9 per cent.

With regard to p_1, if the demand for power were equal to the available supply from the time of the power-plant being put into operation, the works cost of waste power would be the same as the selling price; but, on the assumption that the supply exceeds the demand during the first five years of operation, and that the cost of waste power during this period is only \$7 per horse-power-year.[2]

The average cost of wasted power during the 20 years life of the conductors is:

$$p_1 = \frac{5 \times 7 + 15 \times 21}{20} = \$17.50$$

The economic voltage drop is therefore:

$$e_r = 8.1\sqrt{\frac{9 \times 15}{17.5}} = 22.5 \text{ volts per mile.}$$

A first approximation to the required line voltage may be obtained by the formula

$$E = 5.5\sqrt{[illegible] + \frac{[illegible]}{100}}$$

$$= 5.5\sqrt{50 + \frac{15,000}{200}}$$

$$= 61.5, \text{ or say } 60,000 \text{ volts.}$$

In order to calculate the cost of the line losses, it will be necessary to adopt a figure for the horse-power transmitted, which, when squared, will give the average square of the power during the estimated life of the conductors.

Assuming an average figure for the output during 12 months, a table showing probable demand for power can be constructed as follows:

[illegible]

[illegible]

[illegible]

interest on first cost of conductors; and the total annual charges on active line material will therefore be:

$$2 \times \frac{I^2R \times p_1}{746} \times 3 \times l$$

where R is the resistance per mile of conductor. But

$$I = \frac{P \times 746}{\sqrt{3} \times E \times \cos\theta}$$

where P stands for the horse-power transmitted.

Also: IR = voltage loss per mile = e_r. So that the formula for the total yearly charges on conductors can be written

$$\frac{2 \times \sqrt{3} \times e_r \times P \times p_1 \times l}{E \times \cos\theta}$$

which in this example becomes:

$$\frac{2 \times \sqrt{3} \times 22.5 \times 13,600 \times 17.5 \times 50}{60,000 \times 0.8} = \$19,300$$

Closer Estimate of Economic Voltage.—In order to take into account first cost, life, annual maintenance, and operating charges of every portion of the complete undertaking which may be affected by a change in the transmission voltage, the costs, worked out on an annual basis, may be arranged in tabular form as here shown, where the total charges for the 60,000-volt scheme are compared with the estimated charges for an 80,000-volt transmission. In this particular example, the figures are favorable to the higher voltage; but the difference is small. It would be useless to repeat the process for a voltage lower than 60,000, because the cost would certainly be higher.

Comparison of Costs at Different Voltages.

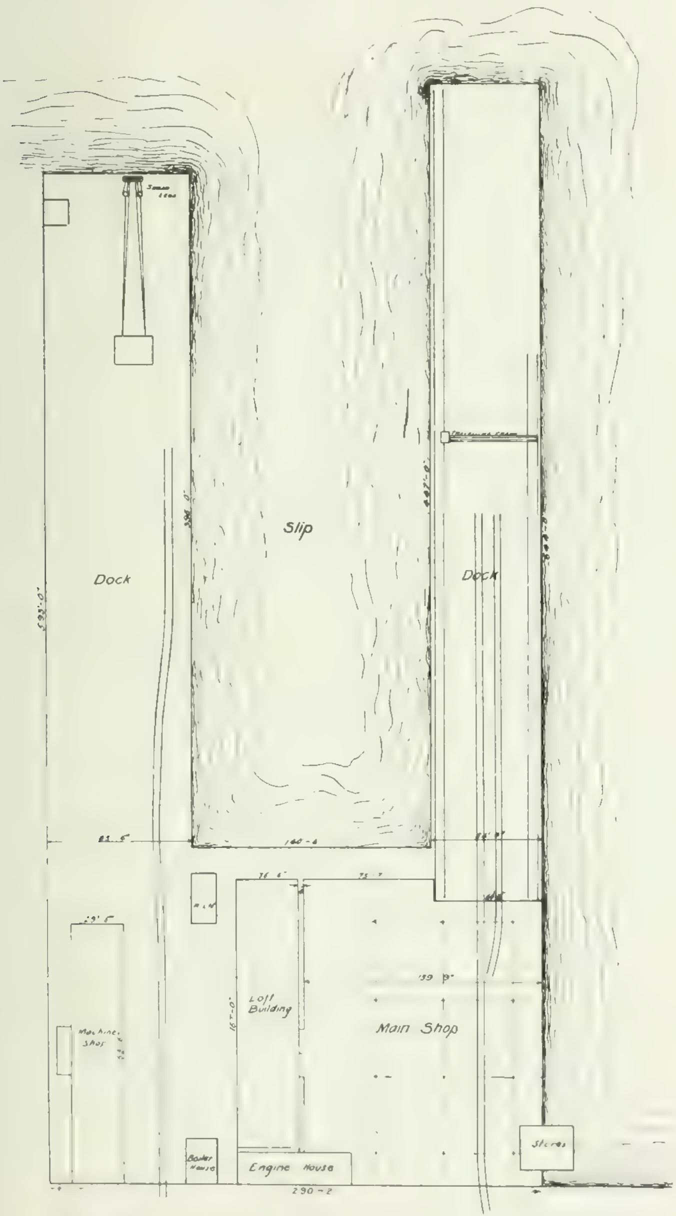
Portion of Complete Undertaking Affected by Change of Voltage	Estimated life (yr.)	Depreciation (from tables)	Depreciation plus 6 per cent.	Total Cost Voltage 60,000	Total Cost Voltage 80,000	Annual Charges Voltage 60,000	Annual Charges Voltage 80,000
Line conductors (copper) of most economic section (annual cost varies as $\frac{1}{\text{voltage}}$)	20			—	—	\$19,300	\$14,475
Steel tower transmission line, without conductors, but otherwise complete (from curves, Fig. 2)	18	3.55	9.55	\$108,000	\$130,000	10,310	12,410
Generating station buildings	40	0.828	6.828	56,000	57,000	3,870	3,895
Sub-station buildings	30	1.505	7.505	11,500	11,900	863	893
Transformers	18	3.55	9.55	32,500	35,200	3,100	3,360
Switch-gear, including lightning arresters, cables in buildings and entering bushings	14	5.10	11.10	27,000	34,000	3,000	3,775
As are unaltered:							
Yearly cost of power lost in generators and transformers							
Yearly cost of operation and maintenance							
Right of way and clearing						\$40,443	\$38,808
Difference in favor 80,000 volts = \$1,635							

It will be understood that the accompanying estimate of total annual charges of the two selected voltages does not include any items other than those that are liable to vary with changes in the line voltage. An estimate covering the complete undertaking would, in addition to the items named, have to take account of [illegible] rights for dam, reservoir, etc., preliminary legal and other expenses; cost of providing proper access for materials to site of work, dam and hydraulic works, generating station building, hydraulic electric generators, and auxiliary plant, [illegible] and contingencies.

In the case of a short distance transmission with a low pressure not exceeding 11,000 volts, and the possibility of winding the generators for the full pressure, the relative costs and efficiencies of generators wound for different voltages should be [illegible].

THE PLANT OF THOR IRON WORKS, LIMITED.

The Thor Iron Works, Limited, of Toronto, has been incorporated with an Ontario charter with the object of manufacturing steel plate work of all descriptions, structural steel for buildings and bridges, to execute marine repairs, and to conduct a general iron and steel manufacturing business. The company has bought the plant and equipment, excepting the land, which is leasehold, and the property of the Grand Trunk Railway, of the Toronto Shipyards Company, successors to the Canadian Shipbuilding Company. The experience of these companies, and of others, led the directors of the new company to the conclusion that a shipbuilding proposition can hardly be made to earn satisfactory dividends here.



General Layout of Plant of Thor Iron Works at Toronto.

The sketch shows the general layout of the plant. The shops are located at the foot of Bathurst Street, Toronto, along the waterfront, and the slips where the docks are located are, therefore, in the protected harbor of Toronto Bay.

Although the plant was originally designed for shipbuilding, and is capable of constructing as large vessels as are in use in Canadian inland waters, it is not the intention of the company to engage in this work. The old layout of the plant will be slightly altered to the conditions shown in the drawing, and the company will manufacture tanks, etc.

The machinery is modern throughout, and is operated by individual electric motors. The plant consists of two large docks, on one of which is a travelling crane, and at the extreme end of the other is a set of shear-legs of 65 tons lifting capacity. The shear-legs will be used for lifting boilers and machinery out of vessels and for raising small vessels out of the water for repairs.

As has been noted, the shops are situated at the foot of Bathurst Street, and are served by a branch of the Grand Trunk Railway. The shops consist of punch-shop, boiler, and engine-house, woodworking shop, machine shop, storehouse and general offices. In the punch-shop is a complete equipment of punches and shears, rolls, planers, steam hammers, etc., with an admirably designed system of cranes to serve them. These machines are all operated by individual electric motors. The main plate rolls have as great a capacity as any in Canada, and the punches and shears have all the attachments for making special cuts that are likely to be called for.

The machine shop contains several lathes, a large planer, a shaper, pipe-cutting and threading machines, and a complete outfit of small tools, while the storeroom is equipped with a large stock of valves, pipe fittings, bolts, etc.

The plant is well adapted to the fabrication of steel plate work for tanks, water-towers, standpipes, etc. No additional machinery or equipment is required. For marine repair work, also, the plant is well laid out. The actual capacity of the equipment now installed is estimated at about 3,000 tons per annum. The company expect that at the outset the principal business done will be in the line of steel plate work, construction of tanks, water-towers, flumes, penstocks, blast furnaces, etc.

The unusual dimensions and capacities of many of the machines have in the past brought special work from many outside plants. The new owners will maintain the policy of placing the equipment at the services of any firm requiring assistance. Plates 19 feet wide may be rolled in the plate rolls and, by means of a special device, the rolls may be used for flanging. The steam hammer and large forges combine with heating furnaces of unusual length and capacity and bending slabs of ample area to make possible the handling of blacksmith work on a large scale. Although originally planned and used as shipyard equipment, this part of the plant is easily adaptable to other work of a similar nature.

The stores contain a great variety of special as well as much stock material. This is being disposed of to a very considerable extent to make room for materials used in connection with the work to be undertaken. Much of the special wood-working machinery will also be eliminated—only sufficient being retained to equip pattern and template shops.

The company have already started work, although it will be a few weeks before they can secure delivery of steel. The plant is being overhauled and put in shape in the meantime.

The company's authorized capital stock is $100,000. The officers and directors are Messrs. J. H. Malone, J. E. Russell, W. Snaith, C. H. Cunningham and W. L. Carr, all of Toronto.

◆

KING EDWARD HIGHWAY.

A portion of the King Edward Highway is to be built of concrete, the contract having been let on September 11th, by the Honorable J. E. Caron, Minister of Agriculture and Highways of the Province of Quebec. The King Edward Highway is the Canadian section of the International Highway connecting Montreal with several large cities of the United States. Ultimately, it is expected that this road will continue as far south as Miami, Florida.

NEW RESEARCH LABORATORY IN CONNECTION WITH SCHOOL OF MINES, KINGSTON.

Under the directorship of H. T. Kalmus, S.B., Ph.D., there has been recently opened in the city of Kingston, Ont., a new research laboratory to be devoted to researches along the lines of the practical application of electrochemistry and electro-metallurgy. This laboratory is the property of the mines branch of the Canadian Department of Mines.

The first investigation, which is now well under way in this department, and which is being done for the mines branch, Department of Mines, Ottawa, has to do with the utilization of the element cobalt. (Canada has produced and is producing millions of dollars worth of cobalt, estimating it at a fair market value, of which only about one-third finds its way into the industries). Although this metal is in many respects similar to nickel, yet, no important alloys of it with other metals are in use. An exhaustive series of researches is therefore being undertaken on "The Metal Cobalt and Its Alloys," for the purpose of increasing its usefulness in the industries.

This research, among others which this new department is conducting, requires an electrical equipment of the most modern type. The laboratory is supplied with electrical power from the power plant of the School of Mining, which is being enlarged for the purpose, and has suitable transformers, bus-bars, switch-boards, etc., to operate its furnaces at any current up to 3,000 amperes, and at varying voltages up to 120 volts. This power equipment, situated as it is in the splendid new Nicol Hall, and with the most modern auxiliary apparatus is probably the most complete electro-metallurgical laboratory in the world.

◆

A 28,000 H.P. ZOELLY STEAM TURBINE.

The firm of Escher Wyss & Co., in Zurich, Switzerland, Canadian office in Montreal, has recently delivered to the Rheinisch-Westfelischen Electric Generating Station In Essen the most powerful steam turbine ever built. When running at a speed of 1,000 revolutions per minute it develops 22,500 h.p. eff. under normal continuous working, [illegible] and a steam temperature of 572 deg. Fahr. at the stop valve and a vacuum of 27.5 inch. (A higher vacuum cannot be obtained owing to the fact that only re-cooled water is available for the condenser). The turbine is also capable of developing 28,000 h.p. continuously and 30,000 h.p. for short periods.

[illegible] "Zoelly" [illegible] turned out [illegible] total [illegible] of the rotor being 26 tons. The total weight of the generator rotor (Siemens Company's make) approximates 60 tons.

[illegible] of oil for lubrication. This oil is under pressure produced [illegible]

[illegible] the turbine, the cooling water being supplied from a cooling tower. A separate turbo-pump then delivers the condensed steam into a hot well, from which the water is in turn delivered to the boiler feed pump.

The attendance of this gigantic turbine-driven alternating unit with its condensing plant is overcome with ease by only three men on each shaft.

◆

LOSSES OF EXPOSED STEAM PIPES.

In a paper read before the British Association it was stated that the effect of the density of the surrounding air greatly enhanced the loss of heat from exposed steam pipes, and that under experimetal pressures of 2,000 lbs. per square inch the heat loss became enormous. Other experiments under normal conditions demonstrated that 1-in. uncovered steam pipe lost in free air 3 b. t. u. per square foot per hour per degree of temperature difference. Out of this total only 15 per cent. was due to radiation and 4 per cent. to conduction. The remaining 81 per cent. was found to be wholly due to convection. In experiments with insulating material it was found that the best of such materials had some thirty times the conductivity of air, so that, were it not for reducing the convection, pipe covering would actually increase the loss of heat instead of diminishing it. This was borne out by the discovery that the heat loss from pipes depended very largely upon the closeness of the packing. If the insulation was very tightly packed, the efficiency was low owing to the increase in conductivity, while, on the other hand, if packed too loosely a large proportion of the convection would still continue. For this reason it appeared that for each class of insulation a certain density of packing was best. In the case of slag wool, this was found to be one-fourteenth the actual density of the individual fibres. In that case the loss by conduction through the insulation to the air would be raised from 0.1 b. t. u. to 0.4 b. t. u. per square foot per degree per hour; loss by convection would be reduced from 3.2 b. t. u. to 0.1 b. t. u. per square foot per hour, the net loss being thus one-seventh of what it would be with bare piping. With bare pipes the character of the service had a distinct influence, but this affected only the loss by radiation. With a good machined surface this loss was reduced from 15 per cent. of the total to about 7 per cent., and if the piping were polished to a mirror-like surface this loss was still further reduced to about 3 per cent. of the total. The loss by convection was not, however, affected in any way, and, as this was the main factor constituting as stated 81 per cent. of the total loss, there was very little to be gained by polishing in the case of ordinary steam pipe temperature. Another factor which was considered was the diameter of the piping. With a small radius the conduction loss was found to become more important, so that the total loss varied with the diameter of the pipe. It was, however, found that this increased loss by conduction only became important with pipes less than ½-in. in diameter, although, as had been previously shown, the loss in the case of fine wire becomes enormous. For pipes above 4 in. in diameter the loss was found to become [illegible] per square foot per degree per [illegible] of the diameter.

[illegible] Rob Roy's [illegible] with Loch Katrine has just been bored through. The length of the tunnel is 3,000 ft., and the inside dimensions are 12 ft. by [illegible] commenced over two [illegible] the rock the pro- [illegible] At each end of the tunnel large [illegible] are to be built.

COAST TO COAST.

Calgary, Alta.—Mayor Mitchell was accorded the honor of turning the first sod in connection with the construction of the Canadian Northern Railway subway entrance to this city.

Province of British Columbia.—It is estimated that the cost of double tracking the lines of the Canadian Pacific Railway traversing the Rocky Mountains will be about $30,000,000.

Ottawa, Ont.—The municipal council have been named defendants in a large number of damage claims arising out of death and disablement following the recent outbreak of typhoid fever.

Vancouver, B.C.—Up to date the expenditure on the Burrard Peninsula joint sewerage has been $21,280, out of the total amount of $35,000 agreed to be spent during the year in preliminary work. To this amount Vancouver contributes $14,000, and South Vancouver, Point Grey and Burnaby, $7,000 each.

Ottawa, Ont.—Twenty-one out of the one hundred and eight joints of the river section of the new intake pipe have already been repaired by divers employed by Messrs. Laurin and Leitch, the Montreal contractors, as far as fixing the bolts or putting on clamps is concerned. To make assurance doubly sure it is the intention to encase each joint in concrete which work will take some time still.

Toronto, Ont.—The Provincial Board of Heath of Ontario contemplate in the near future the oppointment of an engineer to the staff, who will be available to give all municipalities advice as to the sort of works they should construct in connection with plans for waterworks and sewage disposal systems. This will allow the municipalities to engage any engineer they may wish to carry out the work.

London, Ont.—Mr. H. J. Glaubitz, general manager of the hydro-electric department in this city, has presented a good report showing the result of the operation of the utility for the past few months. The statement shows that for the first ten months the department has a gross surplus of $31,784.61, and a net surplus of $15,046.73. This is looked upon as exceptional in view of the fact that $7,000 for the solicitation of business has been charged against revenue.

British Columbia.—The fact that the coal deposits found along the shores of the Pacific are of pre-tertiary origin, and yield no coke, is a circumstance which so greatly hampers the development of the iron industry in British Columbia that the latter, in fact, has to fall back upon suitable imported coke. This being so, Russian enterprise is now being urged to commence the exploitation of the rich deposits of coal in the Island of Saghalien, which are supposed to be the best in the Pacific Ocean, but which hitherto for some reason have been entirely neglected. The geographical position of these deposits is favorable for the export to British Columbia of coal or, perhaps, coke.

Vancouver, B.C.—The city council passed an agreement between the municipality and the Canadian Northern Railway by which the city is prepared to deed over to the railway company 110 acres of tide flat property. The agreement will go before the ratepayers in November. The company will spend $4,000,000 in terminal facilities and $4,000,000 in a tunnel entrance to the city, four miles in length. The proposed depot will cost $1,500,000, and a first-class hotel will be built.

Marlboro, Alta.—Three rotary kilns, each 140 feet in length, eight feet in diameter, made of steel ranging from three-quarters to fifteen-sixteenths of an inch in thickness and weighing 150,000 pounds, exclusive of base and gear, arrived in the Grand Trunk Pacific Railway Company's north yards from Alliance, Ohio, consigned to the Edmonton Portland Cement Company at Marlboro, Alta., 144 miles west of Edmonton. Twelve flat cars, six of which carried the ends of the kilns on swivel blocks, were required to convey the machinery, which weighed 450,000 pounds.

Coquitlam, B.C.—An old proposal to construct a dam across the Second Narrows and thus convert the eastern end of Burrard Inlet into a fresh water lake has now been revived by the municipal council of Coquitlam. This body has forwarded a request to Hon. Frank Cochrane, minister of railways and canals, to withhold sanction to the Second Narrows bridge project until the municipality has had an opportunity to prepare plans for a causeway and locks, and forward them to the department. The application has a connection with a scheme to connect the headwaters of the Pitt River with the Inlet by means of a canal.

Victoria, B.C.—Following the recent educational campaign of the university authorities and parliamentary officials regarding forestry and lumbering methods, the management of the Victoria Lumbering and Manufacturing Company have made a practical application of these teachings and have, after installing a logging railroad, given instructions that all underbrush, snags, down logs, or whatever else might help to spread a fire must be cleared away for at least a hundred feet on each side of the track. This is probably the first time that adequate precautions of this kind have been taken by any lumbering company in this province.

Ottawa, Ont.—The Secretary of the Dominion Railway Board has sent out a circular to the railroads informing them that in all cases of bridge work over water in which there might be the slightest doubt as to it being navigable or not, the railway companies must, in addition to the papers now forwarded in support of their applications, furnish the Railway Board with evidence showing that the question of the navigability of the water has been, in the first instance, taken up with the Department of Public Works; and, secondly, that if the department deems the waters to be navigable, the structure is satisfactory to that department.

Province of Ontario.—The Great Lakes International Pure Water Association and the National Association for Preventing the Pollution of Rivers and Streams will meet in Cleveland on the 23rd and 24th of this month. Dr. Chas. E. Hodgetts of the Conservation Commission, Dr. J. W. S. McCullough of the Provincial Board of Health, Prof. Amyot, provincial bacteriologist, and Dr. Charles Hastings, Toronto, will represent the Canadian interests. The whole range of subjects dealing with water contamination will be discussed, and the conclusions of the conference will be forwarded to the International Joint Commission, which meets to deal with the question next month.

Detroit, Mich.—The Livingstone Channel in the Detroit River, one of the two most important engineering feats on the great lakes, which has cost the United States Government fully $10,000,000, has just been formally opened for navigation. The plans for the initial opening were in the hands of Lieut.-Col. M. M. Patrick, chief the of the United States engineers in charge of the Detroit district, representing the War Department; George A. Marr, Cleveland, secretary of the Lake Carriers' Association; and Homer R. Warren, president of the Detroit Board of Commerce. The length of the channel is eleven miles; its width 300 to 800 feet, and its depth 23 feet, and it has been under construction for the past four and a half years.

Midland, Ont.—At a meeting of the citizens of Midland held recently the construction of the Central Canadian Railway from Midland to Montreal was approved. This company [illegible] some years and are entitled to a very large land grant under a charter granted before confederation. The company have recently floated their bonds in England and have let a contract to a large English contracting corporation for the construction of the railway from Montreal to Midland. An offer has been made to the Dominion Government to grant running rights to the Intercolonial Railway from Montreal to Midland, thus giving the government road a much needed outlet to the lakes and providing them with the means of securing western freight.

Vancouver, B.C.—Mr. E. H. Heaps and Mr. H. Schaake, of the Heaps Engineering Co., successors to the Schaake Machine Works, met the finance committee of the city council of Vancouver and discussed the details of the agreement, whereby the engineering company will lease from the city 697 feet of land on Lulu Island at a yearly rental of $1,742.25, provision being made so that the company can purchase the land at the end of five years for $69,700, or $104,550 if purchased within seven and a half years, and the price to increase to $139,400 if purchased after that time and up to ten years. The company agrees to employ not less than 100 employees and during the term of the lease shall employ white men only. A by-law will be submitted to the ratepayers to ratify the agreement.

Toronto, Ont.—Commissioner of Works Harris states that in his opinion it will not be possible to secure the requisite equipment in sufficient time to operate the civic car lines this winter. To do so, he states, it will be necessary to erect transformer houses, design and build machinery, and erect feed wires, as well as to secure snow sweepers, etc. A gasoline motor or storage battery car might be operated, but sufficient experience has not been gained with these types of unit to justify him in recommending their use. Again, the line has been built with the overhead structure required for trolley operation. Respecting this, the Board of Control recommend that the Commissioner of Works be given full authority to establish an electric service on the above branch of the civic car line system.

Cretna, Man.—The Savoie-Guay Company, of Plessville, [illegible] auto plow of their own manufacture. The machine is of 45 [illegible] thing that a tractor can be used for, for driving all classes [illegible]

The Canadian Pacific Railway.—[illegible]

[illegible]

[illegible] not yet fully developed the local traffic which they are capable of carrying. The length of line in operation upon the system in 1902-3 was 7,748 miles; in 1911-12 the corresponding total was 10,990 miles. The receipts in 1902-3 were $43,957,000; in 1911-12 they had expanded to $123,310,000. But while the Canadian Pacific Railway has yet to develop its full carrying powers and productibility as regards local traffic, one important reason for the high ratio of its working expenses is the high cost of labor. The growth of population will probably moderate this difficulty, and it will certainly add year by year to the local business of the system.

Regina, Sask.—We are informed through Mr. A. J. McPherson, chairman of the Board of Highway Commissioners of Saskatchewan, that Dr. W. W. Andrews, of the Highway Board, has been engaged for some time past in investigating the practicability of treating the gumbo clays, which are spread so extensively over the Province of Saskatchewan, so as to make them more suitable for road purposes. Quite a large section of the Province lying from Weyburn north-west to the Elbow, on the South Saskatchewan River and north of the South Saskatchewan to the Alberta line, consists of a gumbo clay which does not lend itself to making satisfactory roads. Even an application of gravel or broken stone is not a success, as the clay is of such a nature that when dry it is exceedingly hard, and it is almost impossible to prevent hummocks or lumps forming on the road, and when wet it will turn into a liquid, and in a very short time any porous material that is put on the road will be impregnated with this liquid and lost. Dr. Andrews made experiments with tannic acid, which when applied to this clay will take away some of these qualities, the tannic acid being obtained from ordinary straw or hay by means of a certain process. This method has not proved itself up to the present to have a likelihood of success. He has also devised a method of calcining clay by means of burning lignite or straw in a form of kiln on the road. The result from this seems to show that there is some hope of success. When the clay is calcined in this way it does not form a mud, as it will in its natural state, and an experimental piece of road is now being tried on a practical scale with the object of seeing how the objects from the calcination process will stand the traffic, also to find out what it will cost to do a unit length of road by this method.

Toronto, Ont.—The local Board of Health states that [illegible] month of September, water samples have been taken all over the city, including all the pumping stations, the reservoir, and the various districts of the city, in order to detect any other possible source of contamination. The taste [illegible] the water at Exhibition time began at the same time that the filters were put in operation, and was undoubtedly due to a combination of the tar from the sand boxes in the filters, the hypochlorite, and probably to an or- [illegible] down to .1 part per million, before we could eliminate the taste, and as it was then dangerous to have from 8-10 million gallons of unfiltered water and almost unchlorinated water coming into the city, all of the water was put through the filters. Now that the filters have been washed free from the material responsible for the taste, we have been able to increase the amount of chlorine to .25 parts per million without producing taste. Tests for B. Coli while the sand is being stirred up by the pump at the John Street well will be without significance, and in general terms it may be said that Toronto water, as long as it is filtered and chlorinated, is safe drinking water. The water used at West Toronto and East Toronto, however, is not safe, because at times the water is muddy and the chlorine does not work so efficiently. When the sewage is transferred to Morley Avenue and put into the lake, it will make the West Toronto supply very much safer, and the East Toronto supply less so. At present it is only the chlorine that stands between the people and the possibility of sewage infection, and though this has proved satisfactory most of the time, it must be recognized that at the time when the water is muddy and at the worst, the chlorine is not so efficient.

◆

AMERICAN SHIPBUILDING COMPANY'S CANADIAN PLANT.

The company's plant at Port Arthur is referred to in the annual report of the American Shipbuilding Company for the year ended June 30th, 1912. That plant is stated to be in full operation, with contracts for steamers that will keep it busy for the next six to eight months, with additional negotiations pending. It is also well employed in dry dock and repair work. A considerable part of its equipment has been completed and is in operation, and its permanent machine shop, joiner shop and power plant are well under way toward completion.

The surplus of the company for the fiscal year was 0.36 per cent. on the common stock as against 1.1 per cent. in 1911. There was a balance of $580,699 as compared with $637,228 in the previous year. During the year up to the close of navigation, in 1911, marine business continued very dull and discouraging to the vessel interests; but the opening of navigation this year was more encouraging, and at the end of the company's fiscal year there was a fair revival in business.

The company has built and completed twelve vessels and has now under construction nineteen, among them a side wheel passenger steamer, larger than the one built last year, and which, when completed, will be the equal in type, construction and finish to anything afloat on inland waters.

◆

RAILROAD RATES ON PULPWOOD.

Argument was heard before the Dominion Railway Commissioners recently in the application of the International Paper Company, of New York, and a large number of Canadian firms to have the railways justify their recent increase of approximately 1½c. from Ontario, Quebec and New Brunswick points to New York State on pulpwood. The Canadian Pacific Railway, Grand Trunk and Canadian Northern were represented and urged that the new rate was a substitution for a blanket rate which had originally covered a very large territory. On account of the extra haul a line through Richmond, Quebec, had been taken as a dividing point and rates increased beyond that, the advance chiefly affecting American mills. Warning has been given shippers so as to allow them to take the increase into their contracts. The pulpwood interests, on the other hand, urged that the present rates are high enough.

BRANCH OFFICE IN WINNIPEG.

The Canadian Domestic Engineering Company, Limited, have opened a branch office in Winnipeg, to handle its Western business. This company has a very large contract in hand for the new Parliament Buildings at Winnipeg, Manitoba.

◆

PERSONAL.

MR. C. O. MAILLOUX has been appointed assistant to the president of the Granby Consolidated Mining Co., of Canada. This is a new position.

MR. A. W. DAVIS, mining engineer for the Consolidated Mining and Smelting Co., of Canada, has returned to Trail, B.C., after examining prospects in the Skeena district.

MR. WILLIAM H. NICHOLS has been chosen president of the Granby Consolidated Mining, Smelting and Power Co., in place of G. M. Luther, who retires on account of ill-health.

MR. WILLIAM R. WORTHINGTON, B.A.Sc., who has been recently appointed chief sewer engineer for the city of Toronto, was born and educated in Toronto. He is a graduate in civil engineering of the Faculty of Applied Science and Engineering of the University of Toronto, in the class of 1904, and since that time has been chief assistant in the sewers department. During this time he has had charge of the design and construction of some of the largest sewer systems in Toronto, and indeed, in the Dominion. These systems required expert technical knowledge and foresight to meet the extraordinary growth of that city.

Mr. Wm. R. Worthington.

MR. J. M. TURNBULL, mining engineer for the Consolidated Mining and Smelting Co., of Canada, has been chosen a member of the first senate of the newly organized University of British Columbia.

MR. C. N. CLARKE, of New York, president of the Minnehaha Mining Co., recently visited the mine, situated in the Manitou Lake mining district of Ontario, in connection with negotiations for its sale.

MR. F. H. SYKES, O.L.S., D.L.S., until recently Assistant Structural Engineer in the Toronto City Architect's Department, has been appointed Chief Examiner of Plans for the same Department. Mr. Sykes is an honor graduate of the School of Practical Science of the class of 1905.

MR. H. G. SALISBURY, Chief Examiner of Plans of the City Architect's Department, Toronto, has tendered his resignation to the Board of Control. In accepting the resignation, the Board have recommended that his salary be paid until the end of the year in view of his past satisfactory services.

◆

MEETINGS.

Dr. Chas. Hodgetts, of the Conservation Commission; Dr. J. W. S. McCullough, of the Ontario Health Department; Prof. Amyot, Provincial Bacteriologist, and Dr. Charles Hastings, M.O.H. for Toronto, represented Canada at the meeting of the National Association for the Prevention of the Pollution of Water, which was held in the city of Cleveland, Ohio, October 23rd and 24th last.

◆

COMING MEETINGS.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Monthly Meeting will be held in the Rooms of the Society, 413 Dorchester Street West, Montreal, November 7th. Chairman, Henry Holgate.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Annual Convention to be held at Dallas, Texas, November 12th to 15th, 1912. Secretary, A. P. Folwell, 50 Union Square, New York.

NATIONAL ASSOCIATION OF CEMENT USERS.—December 12th to 18th. Annual Convention, Pittsburgh, Pa. President R. L. Humphrey, Harrison Building, Philadelphia, Pa.

AMERICAN CIVIC ASSOCIATION.—Annual Convention will be held at Baltimore, Md., November 19th to 22nd. Secretary, Richard B. Watrour, Union Trust Building, Washington, D.C.

AMERICAN RAILWAY ASSOCIATION.—Nov. 20th. Annual Meeting at Chicago, Ill. Secretary, W. F. Allen, 75 Church St., New York.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. Secretary, E. L. Power, 150 Nassau St., New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

◆

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE. Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—

177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings [illegible] 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh [illegible]

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; [illegible]

[illegible] and third Friday of each month, October to April, in [illegible]

TENDERS.

Longueuil, Que.—Tenders for dredging required here will be received until October 29th, 1912. Full particulars at the office of R. C. Desrochers, secretary, Department of Public Works, Ottawa.

Midland, Ont.—Public building: Tenders to be received until November 5th, at the office of R. C. Desrochers, secretary, Department of Public Works, Ottawa. Plans, etc., at the offices of Mr. Thos. Hastings, clerk of works, Postal Station F, Yonge Street, Toronto, and at the post office, Midland, Ont.

Orillia, Ont.—The town of Orillia has deeded to the government the land for the new armory. Tenders will be asked for at once and work will commence next month. C. E. Grant, town clerk.

Ottawa, Ont.—J. D. McLean, assistant deputy and secretary, Department of Indian Affairs, will receive tenders until November 12, 1912, for the erection of a frame day school building on the Songnees Reserve on the northern shore of Constance Cove on Esquimalt Harbor. Plans, etc., may be seen at office of A. M. Tyson, inspector of Indian Agencies, Vancouver; W. E. Ditchborn, inspector of Indian Agencies, Victoria, and the post office at Nanaimo, B.C.

Ottawa, Ont.—Sealed tenders addressed to the Postmaster-General will be received at Ottawa, until noon of November 29th, 1912, for the conveyance of His Majesty's mails on a proposed contract for four years six times per week over rural mail route from Weston, Ont. Full particulars may be obtained at the post offices of Emery, Weston, and at the office of the post office inspector at Toronto. (See advt. in Canadian Engineer.)

Point Grey, B.C.—The municipality are calling for tenders for the supply of about 33 miles of steel pipe, to be received until December 2nd, 1912. Particulars may be obtained at the office of the water superintendent, Municipal Hall, Kerrisdale (Vancouver), B.C. Ben. A. Cunliffe, clerk municipal council, Kerrisdale, B.C. (See advt. in Canadian Engineer.)

Rimouski, Que.—Tenders for the construction of a line of wharves and dredging tidal basin at Rimouski, County of Rimouski, Que., will be received until November 21, 1912, addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa. Plans, etc., may be obtained at the offices of this department; J. A. Tremble, Esq., district engineer, Montmagny, Que.; A. R. Decary, Esq., district engineer, Post Office Building, Quebec; J. L. Michaud, Esq., district engineer, Merchants Bank Building, Montreal; and on application to the Postmaster at Rimouski, Que.

Regina, Sask.—Separate tenders for the erection of a Normal school building; and the heating and plumbing, and electrical work in connection with the above, will be received until October 26th, 1912. Plans, etc., may be obtained on application to the Builders' Exchange, Winnipeg; or to Messrs. Storey and Van Egmond, architects, Regina; or to H. S. Carpenter, acting deputy minister of public works, Department of Public Works, Regina.

St. John, N.B.—Tenders for the construction of a cribwork and concrete wharf at St. John, will be received until November 1st, 1912, at the office of Alex. Johnston, deputy minister of marine and fisheries, Department of Marine and Fisheries, Ottawa. Plans, etc., at the office of the Department of Marine and Fisheries, Ottawa, and at the office of the agents of the department at St. John, N.B., Halifax, N.S., and Sydney, N.S.

St. Victoire, Que.—Construction of wharf: Tenders to be received until November 11, 1912, by R. C. Desrochers, secretary, Department of Public Works, Ottawa. Plans, etc., to be had at the offices of J. L. Michaud, Esq., district engineer, Merchants Bank Building, Montreal, P.Q.; A. R. Decary, Esq., district engineer, P.O. Building, Quebec, P.Q., and on application to the postmaster at St. Victoire, Que.

Toronto, Ont.—Tenders for the construction of additional targets at Long Branch rifle range, will be received at the office of Eugene Fiset, Col., deputy minister, Department of Militia and Defence, Ottawa, until noon of 4th November, 1912. Specifications, etc., at the office of the General Officer Commanding 2nd Division, Toronto, Ont., and the Director of Engineer Services, headquarters, Ottawa. (See advt. in Canadian Engineer.)

Victoria, B.C.—J. E. Griffith, public works engineer, Department of Public Works, Victoria, is calling for tenders to be received until the 29th day of October, 1912, for the supplying and erecting of laundry and kitchen machines and fittings at the Mental Hospital, Coquitlam.

Winnipeg, Man.—Tenders are to be received until November 15th, 1912, addressed to the Chairman, Board of Control, for the supply of all labor, material and plant required for the execution of the works in connection with the extension of the artesian well water supply system of the city of Winnipeg. Plans, etc., may be obtained at the office of the city engineer, 223 James Avenue, Winnipeg. M. Peterson, secretary. (See advt. elsewhere in Canadian Engineer.)

Winnipeg, Man.—Tenders will be received by the chairman, Board of Control, until October 30, 1912, for the supply of all labor, materials and plant, required in connection with drilling 15 wells, more or less, in accordance with specifications. Plans, etc., at the office of the city engineer, 223 James Avenue. M. Peterson, secretary, Board of Control office, Winnipeg.

Yorkton, Sask.—Tenders are to be received until noon of November 12th, 1912, for one automobile fire truck complete from 50 to 60 h.p., with combination extension ladder, hose and chemical equipment. Plans, specifications to accompany all tenders. T. F. Acheson, secretary-treasurer, Yorkton. (See advt. in Canadian Engineer.)

◆

CONTRACTS AWARDED.

Belle Ewart, Ont.—Mr. Henry Hickey, of Peterboro, Ont., has the contract for the construction of wharf with stone approach at this place.

Bassano, Alta.—The complete contract for material and constructing the water and sewer system for the corporation of the town of Bassano, has been awarded to H. C. Weir, Esq., 507 First National Bank Building, Chicago, Ill., his contract price being $105,490. Geo. B. R. Bond, secretary-treasurer.

Chattie Beach, Kootenay, B.C.—Wharf: Contract awarded to William English, for $5,400.

Chilliwack, B.C.—New armory: Contract awarded to Messrs. Campbell and Wilkie, Vancouver, for $16,350.

Holberg, B.C.—Wharf: Contract awarded to R. A. Wood, for $[illegible].

Montreal, P.Q.—Messrs. Heap and Partners (Canada), Limited, have secured a contract from the Board of Control at Ottawa, for three Rees Roturbo motor-driven pumps with total capacity of 45,000,000 gallons per day.

Orillia, Ont.—The Bell Telephone Company are constructing a new central exchange. Messrs. E. Webb and Son are the contractors.

The Dominion Government will build a new dock at the foot of Mississaga Street. Messrs. Conroy and Co., Peterboro, will be the contractors. The dock will be of concrete.

Ottawa, Ont.—A contract has been awarded to Mr. Antoine Kelly for the sum of $6,391, for the construction of an addition to the customs express warehouse in Montreal.

Stratford, Ont.—Mr. W. Bradshaw has been awarded a contract to erect an addition to the building for the filtering tanks at the pumping station. The cost of this work will be $[illegible]. The addition will be of white brick 30 x 40 feet.

Victoria, B.C.—The contract for the construction of a [illegible] has been awarded to Sir John Jackson, of [illegible] [illegible] for the work. [illegible]

◆

RAILWAYS—STEAM AND ELECTRIC.

Galt, Ont.—The Lake Erie and Northern Railroad has [illegible] of the proposed route [illegible] which it is expected will not meet with [illegible].

Medicine Hat, Alta.—[illegible]

Vancouver, B.C.—The last section of the railway connecting Vancouver with the Kootenay is contracted for. It will cost $100,000 per mile. The contract is for thirty-eight miles.

Victoria, B.C.—The contract for grading a twenty-mile section of the E. & N. railway extension on the east coast of Vancouver Island was awarded to Messrs. Moore & Pethick, by the Canadian Pacific Railway.

◆

LIGHT, HEAT AND POWER.

Brantford, Ont.—The Ontario government has appointed the Canadian Domestic Engineering Company, Limited, of Montreal, as engineers for the heating, ventilating, etc., of the new Brantford Asylum for the Blind.

Moncton, N.B.—The management of the Humphrey Unshrinkable Underwear Company are equipping their mill in such a manner as to allow full benefits to be obtained from the natural gas wells in this vicinity.

Municipality of Saanich, B.C.—The council of this point have decided that the streets must be lighted and are considering one or two propositions that have been made. This municipality is very close to the city of Victoria.

Regina, Sask.—An addition to the lighting facilities of the streets will be made in the east end of this city. The city electrician has been instructed to purchase the necessary materials.

St. Catharines, Ont.—A petition signed by one hundred citizens asking that an estimate of the cost regarding the installation of hydro-electric power into this municipality be given was presented to the council.

Vancouver, B.C.—Owners of sawmills operating in the vicinity of this city have made a proposition to the municipal authorities for permission to lay wires and offer for sale electrical energy produced from steam turbine units operating with sawdust as fuel.

Winnipeg, Man.—The Canadian Domestic Engineering Company have been appointed consulting engineers for the heating, plumbing, ventilating, electric works and central power-house equipment of the new parliament buildings, Winnipeg, Manitoba, involving an expenditure for the buildings of approximately $5,000,000, and for the engineering work of $800,000.

◆

GARBAGE, SEWAGE AND WATER.

Brantford, Ont.—The municipal council will lay a twenty-inch main to Terrace Hill at a cost of $75,000. T. H. Jones, city engineer.

Brantford, Ont.—The municipal council have given serious consideration to the request of the fire underwriters, and have discussed the installation of a ten million gallon pump and an auxiliary turbine pump to the plant now operating at the water works pumping station. The cost of this would be about $65,000. T. H. Jones, city engineer.

Montreal, P.Q.—The municipal council have considered the appropriation of $[illegible] for an investigation of the water waste by the Pitometer Company.

Medicine Hat, Alta.—The new sewerage pumping plant to be erected will be equipped with two centrifugal pumps of a capacity of 1,000 gallons per minute.

Ottawa, Ont.—Certain members of the municipal council have started an agitation to have Lake Dechenes examined and reported upon as a probable source of a pure and reliable water supply for the ratepayers of this city. Ald. Nelson is interested in the project.

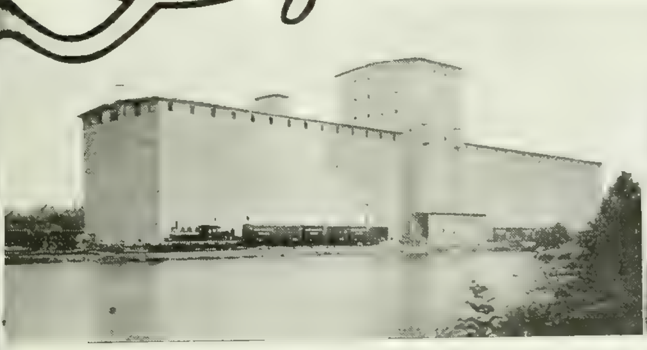
Sydney, C.B., N.S.—The daily press are urging the ratepayers to demand an improved water system of the candidates about to compete for civic election.

◆

BUILDINGS AND INDUSTRIAL WORKS.

Berlin, Ont.—Plans are under preparation for the erection of a new opera house in this city to have a seating capacity of 1,[illegible]. Mr. C. O. Philip is in charge of the matter for the interested parties.

Barrett Specification Roofs



On Four Great Granaries

To cover the four huge granaries illustrated herewith the Canadian Pacific R. R. engineers chose Barrett Specification Roofs for good and sufficient reasons.

These practical men know that these roofs will last *20 years or more.*

They further know that they will need no painting or maintenance expense of any kind and that the net cost per year of service will be infinitely lower than could be shown by any other type of roofing.

It is for these very reasons that Barrett Specification Roofs are used on more first-class buildings in the United States and Canada than any other kind

A big roof generally means a Barrett Specification Roof, for the reason that the cost of big roofs is carefully scrutinized and ultimate economy carefully considered. Small roof areas ought also to have Barrett Specification Roofs, because they are just as economical and satisfactory there.

Copy of The Barrett Specification with tracings ready for incorporation into building plans free on request. Address nearest office.

Special Note

We advise incorporating into plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired however, the following is suggested:

ROOFING Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15th, 1911, using the materials specified, and subject to the inspection requirements.

THE PATERSON MANUFACTURING CO., Limited

MONTREAL TORONTO WINNIPEG VANCOUVER ST. JOHN, N.B. HALIFAX, N.S.

Edmonton, Alta.—The management of the Edmonton Cold Storage have completed arrangements for the erection of a four story plant to cost $115,000. The building will have a storage capacity equal to 100 railroad cars.

Edmonton, Alta.—The management of the Cement, Stone and Brick Company will erect a building in this city for the manufacture of their products. Mr. Hyram Sykes, Calgary, is manager of this concern.

Fort William, Ont.—Construction work has been commenced on a new banking premises to be erected for the Merchants Bank of Canada. Mr. W. F. Bell is the local manager of this bank.

Galt, Ont.—Mr. Andrew Newlands, of the Galt Robe Works, has stated that it is the intention of the company to rebuild their burned plant at once.

Macleod, Alta.—Plans are being prepared for the erection of a $30,000 office building for the Bank of British North America. The manager is F. McRae.

Montreal, P.Q.—Messrs. Walter Baker Company, Ltd., have taken out a permit for the erection of an eight story factory to cost $50,000.

North Bay, Ont.—The management of the Bogart Refrigerator Company have requested the town council to grant a free site of two acres, exemption from taxes, and a fixed water rate preparatory to their decision to erect a plant.

Peterboro, Ont.—The management of the DeLaval Dairy Supply Company have commenced oprations on a new factory to house the manufacture of their products. The building will be 400 x 112 feet. Messrs. J. W. Ferguson Company, of Patterson, New Jersey, U.S.A., are the contractors.

Port Arthur, Ont.—Mr. J. J. Tracey, of Chicago, U.S.A., has been making an examination of this city with a view of erecting a theatre.

Prince Albert, Sask.—The Great Western Iron, Wood and Chemical Company, of Dorchester, N.Y., will establish a branch at this point. Creighton and Crowter, architects. The capital of the company is $500,000 and the directors are: D. H. Hanna, Toronto; F. H. Phippen, Toronto; Hector McInnes and Felix Frank, of Halifax.

Strathcona, Alta.—An hospital to cost $150,000, four stories high, 50 feet wide, 135 feet long, and of reinforced concrete construction, will be built by Wilson and Harrals, architects.

St. Thomas, Ont.—A $3,000 greenhouse will be erected by the municipal council and the Board of Education in Pinafore Park.

Toronto, Ont.—The management of the Northern Electric Manufacturing Company have been granted a permit to erect a new factory on Bay Street at a cost of $75,000.

Toronto, Ont.—The management of the American Abel Company will make an addition to their plant on Queen Street of this city. Mr. F. C. Rumely, of Laporte, Ind., U.S.A., will assume charge of the alterations.

Toronto, Ont.—The directors of the Creche, a local charitable organization, are to make an effort to raise the sum of [illegible] for the purpose of erecting a new building.

Toronto, Ont.—The officials of St. Paul's Roman Catholic Church, Queen and Power Streets, are [illegible] for the [illegible] of a [illegible] parish house and [illegible].

Watrous, Sask.—The management of the [illegible] Company have made arrangements for the [illegible] of a plant at this point as well as at [illegible] and [illegible]. This building will cost about [illegible].

Welland, Ont.—[illegible] Limited, will establish a plant in this city [illegible]. The direct[illegible] made public.

◆

BRIDGES, ROADS AND PAVEMENTS.

Calgary, Alta.—[illegible]

Ottawa, Ont.—There is a probability of the council of this municipality and the officials of the Township of Gloucester and Billings' Bridge erecting a bridge over a ravine near the borders of the city. A meeting will be held on October 31st to decide the matter.

Province of Saskatchewan.—According to a report the government of this province have appropriated the sum of $5,000,000 for the construction of good roads.

◆

CURRENT NEWS.

Province of Alberta.—Mr. J. F. Smith, president of the Mormon church, has stated that there is a possibility of that denomination erecting a large temple at some point in this province.

Brantford, Ont.—The municipal council will serve a notice on the Western Counties' Company requesting them to put the banks of the river at the head gates in a safe condition at once. It is hoped by this means to avert a recurrence of the flood of last spring.

Edmonton, Alta.—The Board of Trade are interested in a proposition calling for the erection of a million bushel grain elevator in this city.

Edmonton, Alta.—Improvements planned by the municipal council for the year 1913 call for an expenditure of $25,000,000.

Kingston, Ont.—The first experiment with an oil driven vessel in the government service is to be made shortly by the Department of Marine and Fisheries. A new boat, to be christened the C. G. S. Dollard, is under construction for the department by the Kingston Shipbuilding Company. The Dollard is to be used in the St. Lawrence Lighthouse Service, under the direction of the Montreal agency. It was originally intended to have the vessel fitted with the ordinary fuel accommodation, but the department has now decided to have her completed with provision for oil. There are up to the present no vessels in the government services using oil as fuel.

Lethbridge, Alta.—The recent announcement made in these columns regarding the erection of a factory addition to the plant of the Lethbridge Brewing and Malting Company now hinges entirely on the water question. The management of the company have stated to the municipal authorities that they must have a consistent water supply. They claim that the water is not properly filtered and that the pressure cannot be relied upon varying as much as 80 pounds in a day or two. Mayor Hatch has stated that to instal a proper filtration plant would cost over $100,000, and at present the city is not in a position to undertake this expense. However, the Works and Property Committee will take the matter up with the city engineer and advise what would be done.

Ottawa, Ont.—The municipal council have not looked with favor on a proposal recently made by the local Board of health regarding the installation of sanitary conveniences in the homes of persons too poor to install them of their own accord and to allow these persons to pay for them during a period of seven years.

Ottawa, Ont.—The municipal Board of Control have recommended the purchase of a tractor for the haulage of the steam fire engine. Mr. Graham is chief of the fire department.

Peterboro, Ont.—Ald. Butler is considering the appointment of an engineer to plan and supervise the installation of a large sewer.

Winnipeg, Man.—The municipal council will [illegible] debentures to pay for the sinking of three new water wells.

DEPT. OF RAILWAYS AND CANALS, WELLAND

Superintending Engineer's Office,
Messrs. Wettlaufer Bros., St. Catharines, Feb. 7th, 1912.
No. 178 Spadina Ave., Toronto.

Dear Sirs :—Replying to yours of the 6th, I beg to say that the two Mixers received from you last summer proved to be very handy, useful machines. They turned out excellent concrete and we had no trouble with them at all.

Yours truly, J. L. WELLER, Superintending Engineer.

CANADIAN NORTHERN RAILWAY

Belleville, Ont., Feb. 14th, 1912.
Wettlaufer Bros.,
178 Spadina Ave., Toronto, Ont.

Dear Sirs :—I think it is my duty to inform you that I am entirely satisfied with the two Concrete Mixers purchased from you last season. I have tested them in every way possible, and in every case I have found them capable of doing first-class work. Yours sincerely, J. O. GIROUX.

We have manufactured concrete mixers and concrete machinery of all kinds for many years; also previously had taken contracts for concrete work of all kinds, and have had the actual experience of just what a concrete mixer should do. Wettlaufer Mixers are perfect to-day through the help of the hundreds of contractors who purchased Wettlaufer Mixers in past years. We have gone personally to them and watched these machines working on all classes of work, asked the contractors their opinions, and so have evolved the present perfect mixer.

Compare the thoroughness, simplicity and durability of our mixer with other makes. The Wettlaufer Mixer is of the heart-shaped drum type; this means quick and positive mixing and the saving of power.

CANADIAN PATENTS.

The following is a list of patents recently issued through the agency of Messrs. Ridout and Maybee, 59 Yonge Street, Toronto, from whom further particulars may be obtained:—H. J. Graves and C. C. Parrott, wheel rims; Wm. C. Gowdy, animal traps; Sir C. C. Wakefield, forced feed lubricator; F. G. Browne, machine for cleaning ships' hulls; George J. Money, latches for doors; Henry Stanbridge, projectiles for ordnance; C. H. Gray, process of manufacture of golf balls; P. M. Bartelmann, clamping devices; W. E. Hipkins, automatic weighing apparatus; Verity Plow Company, molding machines; Minerals Separation, Limited, concentration of copper ores; C. B. Redrup, fluid pressure engine; John Anderson, feathering wind sails for propellers; F. W. Prentice, train control systems; Cummer-Dowswell, Limited, washing machine; Dunlop Tire and Rubber Goods Co., Limited, tire treads.

◆

RECENT CRANE SALES.

Contract has been awarded by the Canadian Pacific Railway Company for a ten-ton overhead traveling crane, of about 57-ft. span, for the Angus Shops, Montreal, to Messrs. Royce Limited, Trafford Park, Manchester, England. Besides this crane, a number of other orders have been booked this year by Royce's Canadian office at Toronto, as follows:—

Two 45-ton; two 30-ton; three 20-ton; two 15-ton; one 10-ton, and three 5-ton overhead electric traveling cranes; a transfer bridge and telfer plant; and the conversion of several hand cranes to electric power.

Among the customers who have ordered these cranes are such well-known firms as Jenckes Machine Company, the Hamilton Bridge Company, the Ontario Hydro-Electric Commission, the C.P.R., the Page-Hersey Company, etc.

Messrs. Royce Limited are very well known all over the world as builders of cranes. They make a specialty of hoisting and lifting machinery, manufacturing absolutely nothing else. They manufacture every portion of their cranes, including the electrical equipment.

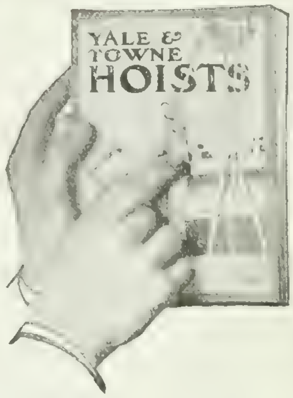
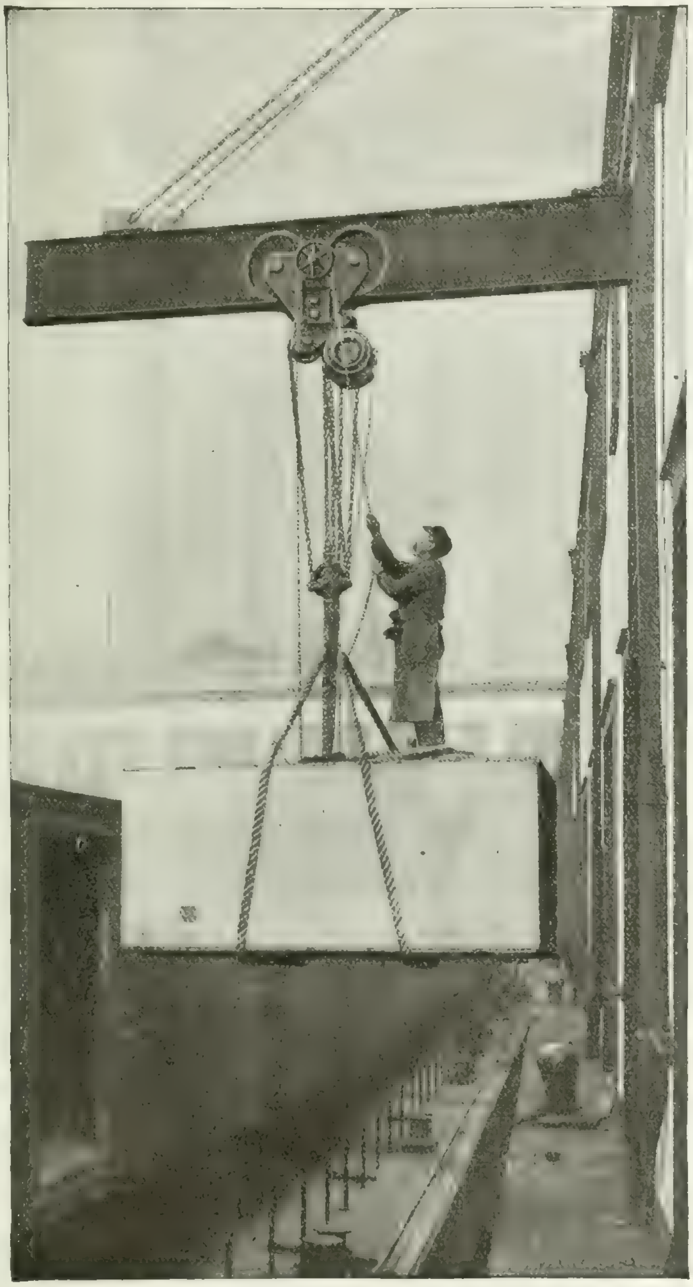
THE TRIPLEX BLOCK

REASONS FOR SENDING TODAY FOR THIS BOOK.





Triplex Block built into a 10-ton geared trolley and used for loading on floats lying alongside a pier in New York City.

A Book on the Handling of Loads, the Latest Practice Here and Abroad.

The change is coming fast. Modern plants today are equipping throughout to give each workman easy mastery over any load up to 20,000 lbs.

The new practice is to reduce all loads to one-man manageable loads, from the raw material coming in to the completed material going out. This frees the factory from an enormous waste. The primitive way of pitting time-paid muscle against stubborn weight, soon costs any manufacturer who stands for it a fortune in wages and restricts his output.

Months of research were spent by Yale and Towne engineers to make this book cover a wide range of conditions, so the man who sends for it will find it the most practical and helpful book that ever came to his desk.

Send for a free copy now, before
the thought is out of your mind.

Triplex Blocks { **16 Sizes:** One-fourth of a ton to forty tons.
9 Active Stocks all over Canada.

[illegible]—October [illegible]—Authorizing C.L.O. & W. (C.P.R.) to construct across tracks of G.T.R., near Shannonville Station, Lot 3, Con. 1, Tp. Tyerdinage, Co. Hastings, Ont., at mileage 69.25 from Glen Tay, by means of overhead [illegible] tracks of G.T.R.

17697—October 10—Directing G.T.R. to protect Ottawa St., Hamilton, Ont., by watchman, in addition to bell already installed, between the hours of [illegible] a.m. [illegible] p.m.

[illegible]—October [illegible]—Authorizing C.N.R. to construct spur, from mileage [illegible], to connect with transfer yard west of Dawson Road, in city of St. Boniface, Man.

17699—October 9—Directing C.P.R. to make grade on south side of track crossing at Lot [illegible], Con. [illegible], Tp. Peel, [illegible] mile west of Wa[illegible] Station, [illegible], to be completed by October [illegible], 1912.

17700—October 9—Authorizing G.T.R. to construct additional track across Richmond St., in town of Strathroy, Ontario.

17701—October 8—Authorizing G.T.R. to construct siding for the proposed Hospital for the Insane, at Whitby, Ont.

17702—September 26—Authorizing C.P.R. to cross highway between Cons. 4 and 5, Tp. [illegible], by means of overhead [illegible].

17703—October 9—Granting leave to Toronto Suburban Ry. Co. to cross C.P.R. by means of under crossing, on Lot 12, Con. 3, Tp. of Toronto, Co. Peel, Ontario.

[illegible]—October 9—Authorizing Municipality of Tp. of Louth, Ont., to construct highway across tracks of G.T.R., between Lots 22 and 23, Tp. Louth.

[illegible]—October [illegible]—Directing G.T.R. to cut down trees on S.E. corner and reduce clay banks on N.E., N.W., and southwest corners, obstructing view of highway crossing 1 mile north of Burk's Falls, Ont., being Cons. [illegible] and [illegible], [illegible].

17706—October 12—Authorizing G.T.R. to carry traffic over Regina-[illegible], Man.

17707—October 11—Authorizing G.T.R. to reconstruct bridge carrying V[illegible], city of Niagara Falls, Ont., across its tracks.

[illegible]—October [illegible]—Authorizing and approving diversion of highway immediately west of G.T.R. station at Thornton, Ontario.

17709—October 9—Approving location and detail plans of G.T.R. proposed new station at Sunnyside, Toronto.

[illegible]—October [illegible]—Directing G.T.R. to reduce to [illegible] ft., the height of cedar hedge, and right-of-way fence, along N.E. side of highway just north of its station at Thornton, Ontario.

17711—October 11—Authorizing G.T.R. to reconstruct bridge No. 75, mileage 8.21, over Grand River, Brantford, Ontario.

[illegible]—October [illegible]—Amending Order No. [illegible], August 13th, 1912, by striking out clause 5 requiring Mount McKay and Kakabeka Falls Ry. Co., [illegible] cars passing over C.P.R. at Neebing Ave., between city of Fort William and Tp. of Neebing.

[illegible]—October [illegible]—Authorizing C.P.R. to construct spur, or switching [illegible] Co., Ltd., on [illegible] Lot [illegible], Con. 6, Tp. Belmont, Co. Peterborough, Ont., near Blairton.

[illegible]—October [illegible]—Authorizing C.P.R. to construct two (2) spurs for [illegible], N.E. [illegible], Tp. [illegible], at Medicine Hat, Alberta.

[illegible]—October [illegible]—Approving C.P.R. plan, dated June [illegible], 1912, showing changes to be made in electric bell protection at Main Street, Carle[illegible], Ont.

[illegible]—October 11—Authorizing C.P.R. to construct spur for [illegible] Yonge St., Tp. York, Co. York, Ontario.

[illegible]—October 11—Authorizing C.P.R. to construct spur for Alberta Foundry & Machine Co., Ltd., Medicine Hat, Alberta.

[illegible]—October 12—Approving revision in line and grade of portion C.P.R. Sudbury-Sault Ste. Marie Branch, as constructed, from M. 7.42 to M. 8.3[illegible] (Webbwood Section), in Lots 4, 5, and 6, Con. 5, Tp. Waters, Dist. Nipissing, Ontario.

[illegible]—October [illegible]—Authorizing city of Hamilton, Ont., to extend Birmingham St. across T.H. & B. Ry. on Lot 7, Con. 1, Twp. Barton, now in city of Hamilton.

[illegible]—October [illegible]—Authorizing city of Hamilton to extend Birmingham Street across G.T.R. on Lot 7, Con. 1, Twp. Barton.

[illegible]—October 12—Temporarily approving G.T.R. Freight Mileage Tariff, C.R.C. No. 11, between and including Prince Rupert and South Hazelton, B.C.

[illegible]—October 12—Authorizing G.T.P. Branch Lines Co. to construct for McLeod Collieries, Ltd., additional spurs and trackage turning out from [illegible], Tp. [illegible], R. [illegible], W. 5 M., Dist. North Alberta, Alberta.

[illegible]—October 11—Authorizing C.P.R. to construct spur for York [illegible], Lots 17, 18, 19, and 20, Block 74, city of Calgary, Alta.

[illegible]—October 12—Extending until November 30th, 1912, time within which C.P.R. construct spur for M. Rumely Company, in city of Saskatoon, Saskatchewan.

17737—October 11—Approving proposed location G.T.R. station on Lot 9, Con. 18, Tp. East Zorra, Co. Oxford, Ont., at Innerkip.

17738—October 8—Authorizing C.N.O.R. to take portion of Lot 15, Con. 4, Tp. Nepean, Co. Carleton, for purpose of carrying out necessary diversion as approved by Order No. [illegible].

17739—October 4—Authorizing C.N.O.R. to construct across Bridge St., village of Yarker, Twp. Camden, Ontario.

17740—October 11—Amending Order No. 17281, dated August 13th, 1912, by striking out word 'Applicants' in 11th and 12th lines of paragraph 1, and in 8th line of paragraph 2, of operative part of Order, and substituting the words, 'the owners of industries applying and interested herein.'

17741—October 11—Authorizing C.P.R. to construct spur for J. T. Hepburn Company, Toronto, Ontario.

17742—October 14—Approving location C.P.R. station at Hussar, Alta., on S.E. ¼ Sec. 14, Tp. 24, R. 20, W. 4. M.

17743—October 14—Authorizing C.P.R. to construct spurs for Tregillus Clay Products Company, N.W. ¼ Sec. 26, Tp. 24, R. 2, W. 5. M., at Shaganappi, Alta., at mileage 5.8, Laggan Subdivision.

17744—October 14—Authorizing C.P.R. to construct spur for Bishopric Wallboard Company, Limited, Sub. Div. Lots 7, 8, and 9, of Lot No. 21, Junction Gore of Tp. Gloucester, Co. Carleton, Ont., at Ottawa.

17745—October 14—Extending for six months, time within which Esquimalt and Nanaimo Ry. file Standard Tariff of maximum freight tolls for approval by the Board.

17746—October 14—Authorizing Esquimalt and Nanaimo Ry. to construct spur for Shawinigan Lake Lumber Company, Limited, Victoria, B.C.

17747—October 14—Authorizing C.N.O.R. to construct across and divert public road, Lot 4, Tp. Bristol, Co. Pontiac.

17748—October 14—Approving C.N.R. plans of its Standard No. 6 station, to be used on its Eastern lines.

17749—October 15—Approving location C.N.O.R. station grounds at Bristol Corners, Tp. Bristol, Co. Pontiac, Que.

17750—October 14—Approving by-law authorizing William McNeill to prepare and issue the tariffs of tolls to be charged by the Western Canada Power Co., Limited.

17751—October 16—Authorizing G.T.R. to reconstruct bridge No. 15, mileage 22.73, across Welland Canal, at a point 1¼ miles north of St. Catharines.

17752—October 11—Authorizing G.T.R. to reconstruct bridge No. 45, mileage 76.83, over Huron Road, between Twps. North & South Easthope, Co. Perth, Ont.

17753—October 11—Directing G.T.R. to install and maintain an electric bell at crossing just east of Jordan Station, Ontario.

17754—October 15—Extending, until June 15th, 1913, the time within which Dominion Atlantic Ry. complete bridge across the Shubenacadie River at South Maitland, Nova Scotia.

17755—October 16—Authorizing C.P.R. to construct branch line across road allowance at southerly end of Sec. 30, Tp. 16, R. 5, W. 2 M., Saskatchewan.

17756—October [illegible]—Relieving G.T.R. from providing further protection at crossing of [illegible] Street, Hamilton, Ont.

17757—October 15—Approving location C.N.O.R. through Tps. Arundel [illegible], Cos. Argenteuil & Ottawa, mileage [illegible] to mileage [illegible].

17758—October 14—Authorizing G.T.P. Branch Lines Co., to construct [illegible], Tp. [illegible], R. [illegible], [illegible], Brandon, Man.

[illegible]—October [illegible]—Authorizing C.N.O.R. [illegible] Laugh[illegible]

[illegible]—October [illegible] Maisonneuve [illegible] St. [illegible] Montreal, Que.

[illegible]—October [illegible]—Authorizing C.P.R. to [illegible] highways [illegible]

Samson Water Wheels

You can always judge a water wheel by the number of successfully operating wheels of that type there are in use—and besides the successful wheels show that the builders have had the right kind of experience, which is important to you.

The Samson wheels in use are developing about *Two Million Horse Power.*

And all the knowledge gained from this extensive experience is back of each new installation.

Send us your next specification.

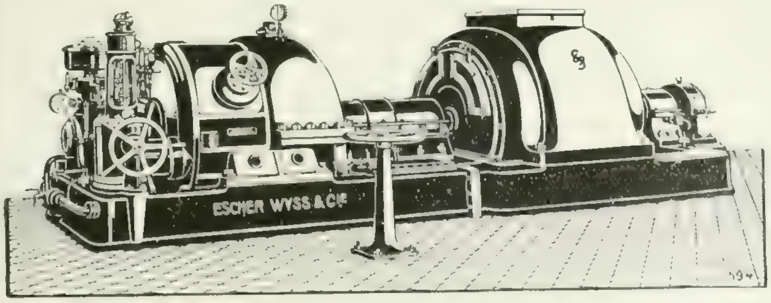
BRITISH COLUMBIA
FRANK DARLING & CO.
Homer St., Vancouver



PHŒNIX, B.C., IS IMPORTANT COPPER CAMP

Phoenix is the most important copper camp in Canada and the mines, up to July 1, 1910, have produced and shipped over 7,000,000 tons of ore.

The ore bodies occur in a mineralized zone which represents a portion of the Brooklyn limestone replaced by epidote, garnet, etc. The zone is separated into isolated areas which occupy trough-like basins in the jasperoids and limestones.

The ore bodies lie at different horizons in this zone though generally favoring the lower and outer portions, and may be considered simply as portions of the mineralized zone in which the copper ore has been sufficiently concentrated to form workable deposits. The ore bodies range in size from lenses about 100 feet long and 20 feet thick to extensive masses like the main ore body of the Knob Hill-Ironside mine, which is about 2,500 feet long and has a maximum thickness of 125 feet and a known width of 900 feet, is the report of Mr. O. E. Le Roy to the Department of Mines, Ottawa. The altitude of the ore bodies varies in different bodies, and at different points in the same body, from vertical to almost horizontal. There is a pronounced flattening of the dip with depth. The foot-wall is usually jasperoid, occasionally limestone, and, in one instance, the quartzose rocks of the Knob Hill group. As a rule, the commercial footwall coincides with the structural. The hanging-wall is almost invariably a commercial one, though the pay ore is usually sharply marked off from the lower grade by a gouge-filled fissure or "slip."

The ore throughout is remarkably uniform and is almost self-fluxing. It consists of finely disseminated chalcopyrite, with pyrite and hematite (specularite), in a gangue composed essentially of epidote, garnet, quartz, calcite, and chlorite. Magnetite occurs in distinct masses, or lense-like bodies, both in, and along the borders of the main ore bodies. In the case of the Monarch deposit magnetite forms one of the main ore bodies. The chalcopyrite carries all the copper, gold, and silver values, the average ore containing from 1.2 to 1.6 per cent. of copper with about $1.00 in gold and silver to the ton. The mineralized zone comprises a portion of a zone of contact metamorphism in the limestone of the Brooklyn formation. In the absence of any closely associated masses of igneous rocks, the hypothesis is advanced, that the metasomatic replacement of the limestone, and the deposition of ore have been brought about by solutions, derived from some unit of the granodiorite batholith. The solutions, given off at temperatures above the critical, and carrying silica, alumina, and ferric iron with copper and iron sulphides at a later stage, traversed the limestone in lateral and lateral descending directions, gradually replaced the limestone by epidote, garnet, etc., and deposited the ore uniformly over extensive areas, thus forming the large low grade bodies. The overlying rocks were subsequently removed, which left portions of the ore bodies outcropping at the surface.

The fact that the ore bodies are comparatively shallow, and that they give out rather sharply with depth, tends to [illegible] descending rather than ascending. The probable age of their formation is provisionally placed in the Jurassic.

In the commercial development of the ore bodies the [illegible] by diamond drilling by means of which the broad outlines of the bodies are ascertained. The ore is [illegible] underground workings.

[illegible] bodies [illegible] vantage.

TOWN OF YORKTON, SASK.

TENDERS FOR AUTOMOBILE FIRE TRUCK.

Sealed tenders addressed to T. F. Acheson, Secretary-Treasurer, and marked "Tenders for Automobile Fire Truck," will be received until 12 o'clock noon, November 12th, 1912, for one automobile fire truck complete from 50 to 60 horsepower, with combination extension ladder, hose and chemical equipment. Plans and specifications to accompany all tenders. The lowest tender will not necessarily be accepted, and the right is reserved to reject any or all tenders.

T. F. ACHESON,
Secretary-Treasurer.

Yorkton, Sask., October 18th, 1912.

CITY OF WINNIPEG.

Tenders for Extension of Water Works System.

Separate or bulk sealed tenders addressed to the Chairman, Board of Control, and endorsed on the envelope "Tender for extension of Water Works System," will be received at the office of the undersigned up to 11 a.m. on Friday, November 15th, 1912, for the supply of all labor, material and plant required for the execution of the following works in connection with the extension of the Artesian Well Water Supply System of the City of Winnipeg, namely:—

Section "B."—Erection of 17 Pump Houses.
Section "C."—Supply and erection of Deep Well Turbine Pumps and Motors.
Section "D."—Supply and installation of necessary voltage Transformers at the individual Pumping Stations.

The Canadian Engineer

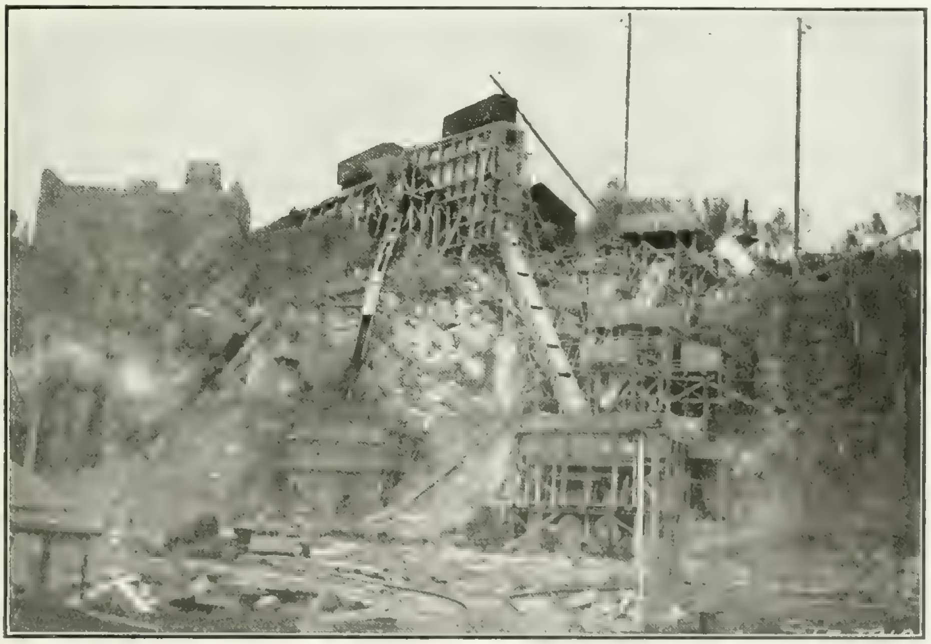
An Engineering Weekly

THE CONSTRUCTION OF THE SOUTH MAIN PIER OF THE QUEBEC BRIDGE.

By H. P. BORDEN, Assistant Engineer Quebec Bridge Commission.

Owing to the fact that the steel superstructure of the new Quebec Bridge is some 21 feet wider and nearly twice as heavy as the old bridge, it was necessary to construct entirely new piers for the new structure. This work has been going on for the past two years, and will probably require another year to finish.

The bridge has three approach spans, two on the north side and one on the south, having a total length of 409 feet, two anchor spans of 515 feet each; two cantilever spans 580 feet each, and one suspended span 640 feet in length, or a grand total of 3,239 feet face to face of abutment. The channel span is consequently 1,800 ft. centre to centre of main piers, being the same as the old bridge.



The Plant on the Side of the South Cliff.

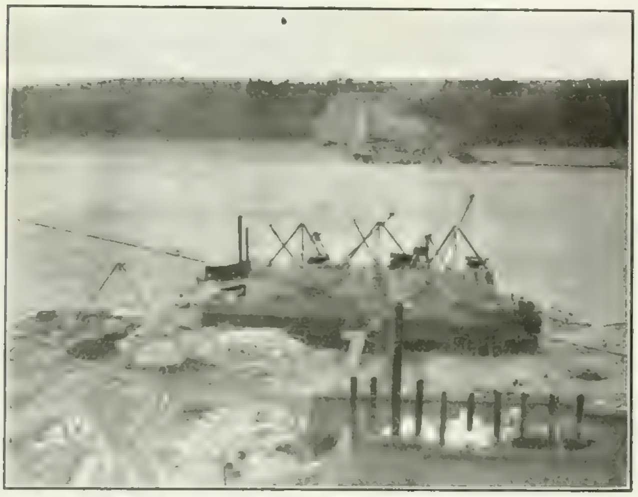
(There can be seen the quarry to the right, with crushers and stone chutes leading to the concrete mixers, also the sand and coal hoppers and chutes leading to the lower level. At the left is the south abutment). June 15th, 1912.

Last season the caissons for the north main pier were successfully sunk to a solid bottom some 80 feet below high water, or 50 feet below the bed of the river. This season the contractor has concentrated his efforts upon the sinking of the mammoth caisson for the south main pier. The caissons for the north main pier were in two sections each 60 ft. x 85 ft. with a 10-foot span between, this space being filled with concrete after the sinking was effected. On the south side one single caisson is being employed 180 ft. x 55 ft., which, taking into consideration the great depth it must go, is by far the largest caisson ever employed on a work of this kind. The caisson is being carried down to solid rock 85 feet below the level of the river bed and 100 feet below extreme high water.

The caisson was floated into position last season and grounded on a prepared bed which is exposed at low water. It remained here all winter, guard piers of rip-rap being placed along its sides to protect it from the ice. The rip-rap was mostly broken concrete taken from the old pier in course of demolition situated just outside the caisson. Weep holes were provided in the roof over the working chamber to allow free movement of water during the high tides, and thus guard against any floating of the caisson when once properly grounded. As the water rose several feet each tide above this roof it was feared that if snow were allowed to accumulate ice would form and tend to strain the structure. To guard against this contingency, the caisson was entirely housed over, and as a further precaution steam pipes were led around the walls just above the roof of the working chamber, steam being supplied by a boiler on top of the caisson. It was found, however, that the steam heating was not necessary as the interior kept sufficiently warm to prevent ice from forming.

Owing to a very late spring, actual sinking operations were not started until June 15th. Since that date the work has progressed steadily, and at the time of writing the caisson has reached bed rock, some 85 feet below the bed of the river. The material, being mostly sand, has been exceptionally easy to penetrate, the rate of progress having averaged nearly 9 inches per day for the entire time. Some weeks, however, the rate has averaged as high as 15 inches per day.

Owing to the unusual size of the caisson, extraordinary precautions were considered necessary to provide against any unequal settlement or any twisting or other movement of the caisson which might tend to open up the joints and seams and consequently allow air to escape. On this account it was decided that the ordinary method of sinking, where all the load is carried on the cutting edge, would not allow the movements of the caisson to be sufficiently controlled during the actual sinking. The rather unusual method has therefore been employed of carrying the entire load on the bulkheads and the roof and no load at all on the cutting edge.



The Plant on the South Side, Showing Caisson During Sinking.

(The plant on the north shore across the river can be distinguished.)
July 15th, 1912.

The caisson was supported on 40 sand jacks and about 25 posts 12 x 12 yellow pine and 54 sets of blocking. The jacks and posts bear directly against the roof while the blocking is piled under the bulkheads. When ready for a drop the blocking and posts are first removed by washing the sand from under them with a water jet. Then the whole caisson is lowered by operating each sand jack simultaneously. The sand jacks are of simple construction, consisting of a steel cylinder 29 inches in diameter closed in at the bottom. Near the bottom are two holes about 3 inches in diameter with a sliding cover. The plunger is a single piece of timber fitting easily into the cylinder. The cylinder is [illegible]

Floating the South Caisson into Position.

[illegible]

[illegible]

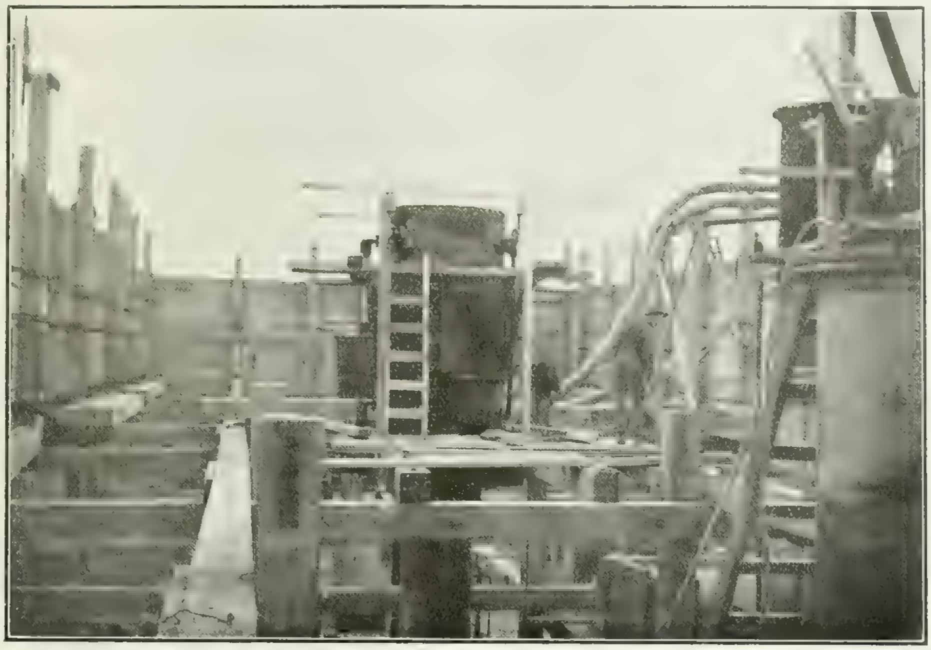
[illegible]

depth of two or three feet. This space was then filled with clay, which tended to prevent the escape of the air, and further acted as a lubricant during sinking. This scheme was followed throughout the entire sinking and seemed to materially facilitate the operation. The material encountered varied from small boulders and sand at the top to practically 95 per cent. sand towards the bottom. The sand is blown out through four-inch pipes by means of the compressed air. Ten of these pipes are in use and remove the fine material very rapidly. The larger material is removed through the material shafts in half-yard steel buckets. It has been necessary to do very little blasting.

Owing to the great depth of the caisson, special means have been employed to enable the men to enter and leave the working chamber with the least possible loss of time and labor. To this end an open shaft extends down to a horizontal steel lock placed over the roof of the working chamber. This lock is large enough to hold the entire shift. Communication with this lock and the outside air is made by means of a spiral stairway. There is an air valve at the [illegible] of this shaft and also at the top of another shaft in the [illegible] of the lock leading down to the working chamber. [illegible] there are four other 30-inch ladder shafts. The excavated material is hoisted out through three material shafts.

Contractors' Plant on South Side of River, New Quebec Bridge

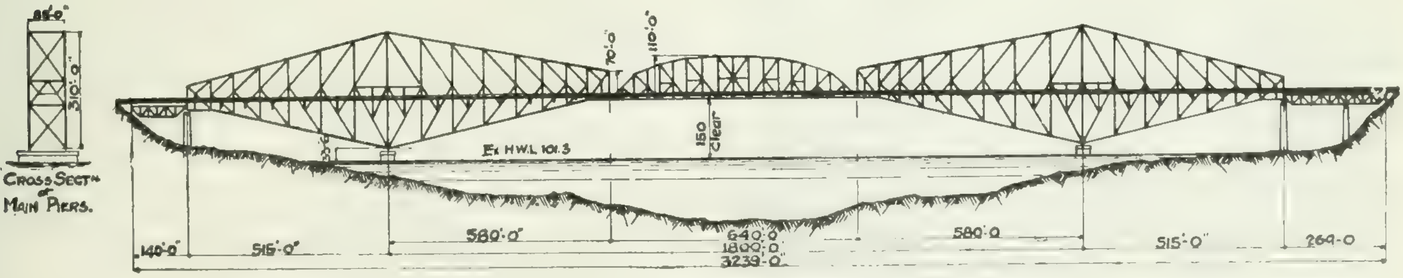
At the beginning of the work about [illegible] "sand hogs" were used in three eight-hour shifts of [illegible] men each. As the caisson was sunk and the pressure increased the length of the shift decreased. At [illegible] feet below average high water at a pressure of [illegible] lbs. per square inch, a change in working hours was made to four shifts of six hours each. At a further depth [illegible] the pressure six shifts of four hours was required. Again at 75 feet the shifts were changed to eight of three hours each. When the caisson reached its full depth of over 90 feet below average high water two one-hour shifts per day were required, this being the greatest length of time that the men could stand the very heavy pressure.



View of Interior of South Caisson.

(The large shafts are for material, while the smaller are ladder shafts for the men). June 15th, 1912.

Outside the caisson the contractor has made provision for the care of the men in many ways. In addition to a bunk-house and dining-room, there is a dressing and coffee house where "sand hogs" coming out of the caisson may change their clothes immediately and be supplied with hot coffee. Next door is an hospital with cots and a qualified doctor in constant attendance. Adjoining the hospital is a steel hospital tank connected with the compressed air pipes where men who have come out of the pressure too quickly and are attacked by the "bends" can be placed immediately under pressure again before any serious or injurious effects can develop. The caisson is surrounded on three sides by a heavy platform supported on bents. On this platform is a double line of track leading to the concrete mixers and stone yards. The skips with the loaded concrete buckets run from the mixers to the caisson by gravity, the empty skips being hauled back by horses. Three 15-ton stiff-legged derricks are placed on each side of the caisson and are used to deposit concrete, stone, or hoist the loaded buckets through the material locks. On this platform is also the pump which supplies the water to the boiler plant and for various other uses as required.



General Elevation and Cross Section of New Quebec Bridge.

(St. Lawrence Bridge Co. Ltd., contractor for superstructure).

The boiler and air compressor plant is situated near the foot of the cliff. A portion of this plant was brought over from the north shore last fall after the sinking of the north caisson was finished, but this has been increased nearly 100 per cent. in order to afford a greater reserve supply in case of break-down and also to furnish air for the increased number of blow pipes necessitated by the greater quantity of fine material encountered in the sinking.

The compressor plant consists of five Ingersoll-Sargeant direct compressors, four with a capacity of 1,250 cubic feet, and one with a capacity of 2,500 cubic feet per minute. This plant was used on the north shore last season. To this has been added, this season, two compound two-phase air compressors bringing the total capacity up to 13,100 cubic feet per minute. These two latter compressors were used only when the pressure got above 30 lbs. per square inch. The air is first compressed in the low-pressure cylinder up to 30 lbs. per square inch, then it is passed through a cooling chamber into the high-pressure cylinder where the compression is increased as desired. There is in addition a smaller high speed compressor for supplying air tools, etc. In the compressor house there is an automatic register indicating on a diagram the pressure at all stages of the tide during the whole 24 hours. Another gauge, by means of a finger operated by the tide, indicates on an adjustable scale what the pressure should be at any stage of the tide. By this means the operator can, by watching the finger, so adjust his compressors so that a pressure is intelligently maintained conforming to the height of the tide. The air is led from the compressor house into two receiving tanks, which tends to absorb the sound and shock from the compressors; thence into two 12-inch mains which are laid in a trough of cold, running water. The air, therefore, enters the caisson comparatively cool, the temperature of the working chamber rarely exceeding 80 degrees Fahr.

The boiler plant consists of one 75, six 100 and three 125 horsepower horizontal boilers, and three 250 horsepower Heine water tube boilers with a total capacity of 1,800 horsepower. A number of 50, 75 and 100 horsepower boilers are also used throughout the work, crushers, mixers, derricks and pumps.

The whole plant, as well as the working chamber of the caisson, is lighted by electricity supplied by the city.

In case of break-down on the power line the contractor has provided a complete generator plant located on the compressor house. It is equipped with a 30- kilowatt General Electric Company generator capable of operating 16 arc lights and 100 sixteen-candle-power incandescent lights.

The concrete masonry plant is situated at the foot of cliff which rises almost perpendicular for 125 feet. Half way up the cliff a No. 5 and No. 8 rock crusher is situated. The stone is quarried directly on the brow of the cliff, and is so situated that one derrick can pick up the buckets of stone from the quarry and dump it into the chute leading to the crushers. Coming from the crushers the broken stone is led through a revolving screen, thence through another chute to a hopper opening onto the mixing platform. Two Smith mixers are used, each having a capacity of 1⅓ cubic yards. The sand is brought to the brow of the cliff in cars and dumped into a large hopper. A chute leads from this hopper directly to the mixing platform. The coal is brought to the lower level in the same manner and is carried to the boiler house in side dump cars.

Sketch of New Quebec Bridge

(as it will appear when finished).

For the convenience of the "sand hogs" the contractor has erected a bunk-house adjacent to the work with sleeping accommodation for about 100 men. A dining-room is run in connection, which will accommodate about as many more.

The south main pier, when completed, will contain about 35,000 cubic yards of masonry. For a height of 75 feet [illegible] it will [illegible]

The Work of Demolishing the Old Main South Pier.

[illegible]

[illegible]

[illegible]

The concrete used for the main body of the caisson is composed of one part cement, two and one-half of sand, and five of broken stone. For sealing the working chamber a somewhat richer mixture is specified, viz., one of cement, two and one-half of sand, and four of stone. Displacer stones one-half a cubic yard and over are used in the concrete, no two stones to be closer than 9 inches vertically or 12 inches horizontally.

The work is under the supervision of a board of engineers, appointed by the government, of which Mr. C. N. Monsarrat is chairman, having associated with him Mr. Ralph Modjeski, of Chicago, and Mr. C. C. Schneider, of Philadelphia. Mr. J. D. Wilkins is resident engineer for the board at Quebec, and has charge of all inspection. Messrs. M. P. and J. T. Davis, of Quebec, have the contract for the masonry, Mr. S. H. Woodard, of Noble and Woodard, consulting engineers, New York, being superintending engineer for the contractors in charge of the entire work.

NICOL HALL, A NEW ADDITION TO QUEEN'S UNIVERSITY.

On Wednesday, October 16th last, there was formally opened for inspection an addition to the many handsome buildings of the University that will in future be known as "Nicol Hall," in recognition of the many philanthropic deeds of Prof. William Nicol.

The building will be occupied by the mining and metallurgical departments and the basement of the building is given over to the fire laboratories, gasoline furnaces, gold and silver mills, balance-room with chemical laboratories, metallurgical laboratory, equipped with roasting furnaces, blast furnaces and necessary appliances, etc.

On the main floor there is a large classroom, with accommodation for eighty students, there are research laboratories, and Prof. S. F. Kirkpatrick's room. The halls are very bright and it is the intention to use them for a museum.

The second floor contains a drafting room, lecture room, a private office and library of Prof. John Gwillim.

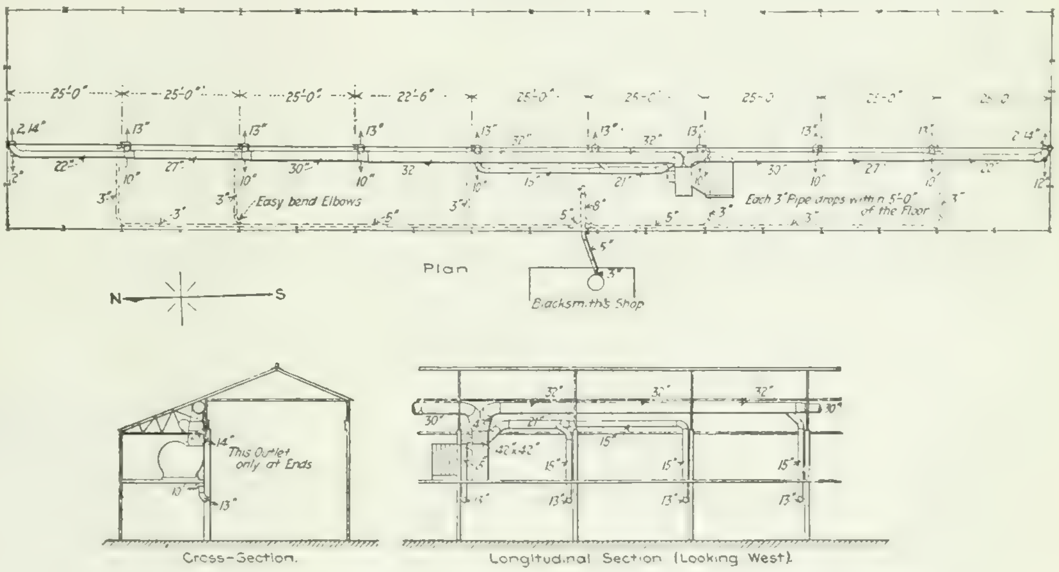
The third floor has not been fitted up as yet.

HEAT TRANSMISSION THROUGH CORRUGATED IRON.

An investigation to determine the coefficient of heat transmission through corrugated iron sheathing has recently been conducted by the Green Fuel Economizer Company, of Matteawan, N.Y., with the view of securing reliable data to be used in the calculation of the heating requirements of such buildings. Experiments were made in a shop of the company, used for the manufacture of fans and blowers.

The building is 225 ft. long by 48 ft. wide, with an average height of 32 ft. There are continuous windows on one side 15 ft. high and on the opposite side 19 ft. high. Otherwise the building is covered with corrugated iron of single thickness without lining. The crevices at the eaves are filled with asbestos and the corrugated iron is cemented in at the bottom, and other measures have been taken to make the building as air tight as possible. The exposure of the windows is east and west, the smaller windows being on the east side.

A study of the available data on the subject showed the coefficient for the rate of heat transmission through single windows with a southern exposure to be 1 b.t.u. per square foot per hour per degree difference in temperature between inside and outside, according to Prof. Homer Woodbridge. For northern exposure the same authority suggests adding 35 per cent., for eastern exposure 15 per cent. and for western exposure 25 per cent. According to Mr. Ludwig Dietz, quoting Dr. Rietschel, of Berlin, and also the specifications of the Prussian Government, the coefficient for single windows is 1.026, with an increase of 10 per cent. for northern, northeasterly or northwesterly exposures and 10 per cent. for especially strong winds. The only figure for corrugated iron without sheathing that has been found is one of 2.132 by Dr. Rietschel, but without any statement as to whether this refers to superficial wall area or to the actual surface of the iron.



Plan and sections of New Fan Building, Green Fuel Economizer Company.

The formula commonly employed for the determination of the coefficient of heat transmission from one fluid to a solid substance and from the solid to a second fluid is of the form,

$$k = \frac{1}{\frac{1}{Ai} + \frac{1}{Ao} + \frac{x}{e}}$$

wherein Ai is the transmission from the inside fluid to the wall surface and Ao is the coefficient of heat transmission from the outside wall surface to the second fluid, e is the conductivity of the material in heat units per square foot per hour per degree difference per inch of thickness, and x is the thickness in inches.

For the value of Ai and Ao Mr. Grashof gives the following equation:

$$a = c + d + \frac{(40c + 30d)}{10{,}000} T$$

in which c depends upon the velocity of the fluid. Dr. Rietschel gives for air at rest c = 0.82; in slow motion, as in contact with cold windows, c = 1.03; in rapid motion, as outside of buildings, c = 1.23. d for glass is given as 0.60 and for sheet iron as 0.57. T for single windows is given as 36, no value being given for iron.

Calculating from the above values, we find that for a single glass window Ai is 1.84 and Ao is 2.07. For sheet iron the value for Ai equals 1.81 and for Ao equals 2.04.

For e Dr. Rietschel gives 190 for iron and 6.6 for glass. It will therefore be seen that the third term in the denominator of the expression for k can be neglected for iron and is practically negligible for glass.

Using the values of Ai and Ao just found, k for a single window works out as 0.958 and for a single thickness of sheet metal as 0.955, practically the same.

This, however, is not taking account of the additional surface of the sheet metal wall due to the corrugations. The corrugated metal used in the building under discussion has one corrugation to every 2½ in., the depth of the corrugation being 1 in. The actual surface of the metal is approximately 1.35 times the superficial area. This would make the rate of heat transmission for corrugated sheet iron, figured on the basis of superficial area, approximately 1.35 times 0.955, or 1.29.

According to the engineers conducting the test the values obtained by Grashof's method for both glass and sheet iron are lower than the values used in ordinary practice. This may possibly be explained on the hypothesis that the constants used in ordinary practice have been increased to account for losses due to leakage, the opening and shutting of doors, etc. Weight is lent to this view by the results of the tests which follow, bearing in mind that the construction of the present building makes it practically air tight. At the same time the values obtained were slightly greater than Grashof's formula would call for. The sheet-metal-working machinery and shafting housed in the building were in constant operation during the test, producing heat which was not measured, while, on the other hand, doors were being opened for the passage of men and materials on an average of once every ten minutes.

The total surface of the building is made up of approximately 7,538 sq. ft. of window, including the sash, 8,247 sq. ft. of wall surface and 11,925 sq. ft. of roof, the walls and the roof being given in superficial area. The total of wall and roof areas is 20,172, which, increased by the factor 1.35 to account for the corrugations, gives 27,130 sq. ft. total metal surface. The total superficial expanse of the building is 27,710 sq. ft., and the total actual surface, counting the metal in the corrugations, is 34,658 sq. ft.

The building is heated by a Green's hot-blast heater, consisting of an engine-driven centrifugal fan drawing through a "Positivflo" heater made up of six sections of four rows of pipe each, the sections measuring 7 x 8 ft. The heater is ordinarily drained of condensate and air by a Dexter vacuum system. There are altogether 6,816 lineal feet of 1-in. pipe in the heater, or 2,272 sq. ft. of heating surface. The air is distributed throughout the shop by circular sheet iron conduits with outlets directed down into the zone occupied by the workmen.

The fan and heater had been running for about two hours when the first readings were taken at 8:30 a.m., and the temperature of the shop was maintained constant until readings were discontinued at 11:30 a.m.

During the test the fan was run at 258 r.p.m., receiving 22,416 cu. ft. of air per minute, figured to 50° Fahr., the air actually being received by the heater at 73° Fahr. and delivered from the fan at 156° Fahr. The temperature of the steam in the heater was 212° Farr. The temperature of the air delivered from the farthest outlet was found to be 141½° Fahr. Under these conditions the temperature of the building, measured 3 ft. from the floor, was 66° Fahr., and measured in the gallery 70° Fahr., the temperature out of doors being 15° Fahr.

For the determination of the total heat two methods were employed. First it was calculated from the amount and rise in the temperature of the air passed through the heater, and, secondly, from the condensation in the heater. For the latter purpose the steam pipe from which the steam was introduced to the heater was carefully drained and the condensate from the heater was weighed. Figured by the air method, the consumption of heat was 2,084,000 b.t.u. per hour, and by the condensate method 2,029,730 b.t.u. per hour.

Using the air figures, the average rate of heat transmission through the superficial area of the building, that is, not counting the corrugations, was 1.42 b.t.u. per square foot per hour per degree difference, and using the steam value 1.38 b.t.u.

According to Professor Woodbridge's figures for the rate of heat transmission through the windows, the result obtained for a window on southern exposure equals 1 b.t.u. per square foot per hour per degree difference, which, however, is to be increased 15 per cent. for eastern exposure and 25 per cent. for western exposure, or in the present case an average of approximately 20 per cent. Figuring the window surface as 1.2, the value for the corrugated iron, figuring superficial area only, is 1.5, or figuring the whole surface of the iron 1.13, that is, less than an equivalent amount of glass surface. According to the engineers the explanation in that case may be that the corrugations in the iron protect the surface to a certain extent, that is, that the rate of heat transmission per square foot of actual surface (instead corrugated area) is less than it would be if transmitted through a flat iron surface.

Using the value obtained by Grashof's method for the glass windows, namely, 0.958, the value for the actual iron surface would be [illegible], but, in the opinion of the engineers, on the basis of this formula, there would be no reason for assuming [illegible] such difference between the iron and the glass.

Allowing for the usual indeterminate conditions, it is suggested that in calculating the heat supply for buildings of this kind provision be made for a coefficient of transmission of [illegible] b.t.u. for the whole wall and roof area.

The coefficient of transmission through the surface of the heater tubes, by the way, was [illegible] b.t.u. per square foot per hour per degree mean difference in temperature between the air and the steam, figured by the ordinary arithmetical method in which the average difference in temperature between the steam and the air is assumed to be the difference between the steam temperature and the mean of the air temperature on entering and leaving.

Figured according to the logarithmic formula, which takes account of the fact that the air arises more rapidly in temperature in passing over the first rows of tubes than in passing over the later rows of tubes, the value is 10. The mean physical velocity of the air through the heater was 1,210 ft. per minute.

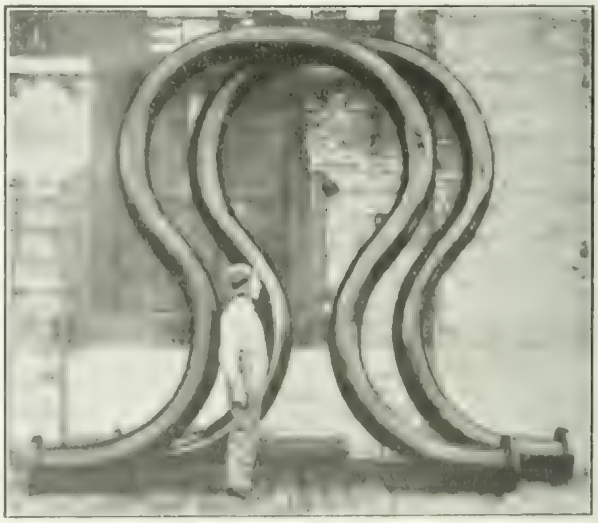
In a subsequent test, with air entering at 72° Fahr. and leaving at 166° Fahr. and steam at 213° Fahr., in which the velocity of the air was 760 ft. per minute, a coefficient of transmission of 7.5 (logarithmic) was obtained. Ten and seven and a half are in the ratio of 0.64 powers of the respective velocities, that is, the coefficient did not vary directly as the velocity, as frequently asserted. If instead of mean velocity flow in pounds of air per minute through the heater is used, which amounts to the same thing as velocities reduced to a standard temperature, the coefficients are found to be in the ratio of the 0.62 powers of the rates of flow.

◆

LARGE PIPE BENDS.

The illustration shows two "N" bends each containing 34 feet of 10-inch full weight pipe, made for the city of Lethbridge, Alberta, and ordered through the Winnipeg, Manitoba, branch of Crane Co. These bends measure 11 feet 10 inches, face to face, and 10 feet 11 inches, centre to centre in height. They have a 3-foot 2-inch radius with four 10 by 17½ extra heavy No. 295 E. welded flanges. The weight of each bend is 1,570 pounds.

The bends are part of the main steam piping in the Lethbridge power plant. One bend is in a vertical position, suspended from the roof truss, the other lies horizontally, supported from I-beams in the [illegible]. The working steam pressure of the line is 160 pounds, with superheat of 130 degrees. The engineer of the plant preferred to take care of expansion with these large "N" shaped bends rather than with sliding expansion joints. The specifications called for piping having a tensile strength of [illegible] pounds to the square inch, an elastic limit of [illegible] pounds per square inch, elongation of [illegible] per cent. in 8 inches, and a reduction in area of [illegible] per cent. Owing to the large size of the bends they had to be welded at the top of the bend, there being about [illegible] feet of straight pipe at that point.



Large Pipe Bends for Lethbridge, Alberta.

CHEMISTRY OF SEWAGE PURIFICATION.*

By Dr. Arthur Lederer.†

Sewage may be purified in part either by mechanical, chemical, or biological means, in combination or separately. Thorough knowledge of all the agencies at work in the biological purification of sewage has not been attained. The clarification of sewage by chemicals is easily explained by the reaction taking place, and the mechanical action of the floc formed. Since biological treatment is very largely used, more time will be devoted to that general process.

Unless specifically stated to the contrary, the remarks in this paper refer to dilute domestic sewage, and not to trade wastes. The treatment of sewages containing trade wastes, or of trade wastes themselves, is a problem in itself, requiring many different processes. The chemistry of the purification of trade wastes depends largely on the character of the wastes. As a rule, such wastes do not interfere with the common methods of disposal, unless they are present in in excessive quantities, or are poisonous, either to men, animals, or fish.

Physical Characteristics.—The physical characteristics of weak domestic sewage, from a large sewerage area as represented by the area draining to the 39th Street testing station, in Chicago, are subject to variations, depending, in part, on the rain-fall or snow-fall. In dry weather the sewage appears turbid, with a yellowish cast from the urine and feces; a perceptible quantity of settling suspended matter is present, in color ordinarily light gray, changing to dark gray, or even black in the storm-water sewage. The odor of the fresh sewage is slightly gaseous, but not at all repugnant as might be supposed. Other sewages might show different physical characteristics, depending upon the water consumption and other factors. As a rule, American sewages are far more dilute than foreign sewage, because of the great waste of water in the United States. A European sewage may, therefore, have not only a more repugnant appearance, but will often possess a strong putrid odor. The development of such an odor depends upon the amount of oxygen in solution.

Changes in Sewage on Decomposition.—The sewage handled at the 39th Street testing station contains some oxygen in solution, as well as nitrites and nitrates, during the greater part of the year, in particular during the winter. Such a sewage is called a fresh sewage. When the oxygen content—the dissolved oxygen as well as the oxygen in the nitrites and nitrates—becomes exhausted, the sewage turns stale, and the organic matter begins to break down, marking the first step toward the ultimate mineralization of the organic putrescible matter,—a change due mainly to the powerful activity of bacteria and enzymes. At this stage the free ammonia gradually increases, combining with the carbon dioxide to form ammonium carbonate. The organic carbon is oxidized as long as free oxygen persists in the sewage. Eventually anaerobic decomposition follows, resulting in the formation of gaseous decomposition products, of which hydrogen sulphide is very prominent. Free nitrogen is likewise released. The sewage becomes septic. The larger the proportion of putrescible matter present, and the smaller the amount of oxygen in solution, the quicker does a sewage become septic. The carbonaceous and nitrogeneous compounds present in the sewage are further attacked by anaerobic micro-organisms,—an action which frequently produces a nuisance.

The term septic has never been strictly defined, but may cover the lack of oxygen in the fluid, and the toxic or septic effect of anaerobic decomposition products upon aerobic organisms. Sometimes reference is made to an over-septic condition, which, to the writer's understanding, is one based upon the inhibition of the growth of anaerobic organisms by their own decomposition products. The term to-day is used vaguely, and requires standardization.

Physical Record.—In our laboratory we record the physical properties, as well as the quantities of settling suspended matter in the sewage, and any peculiarity in color. Sometimes the color becomes distinctly yellowish, a reddish precipitate gradually settling out. In such a sample the alkalinity is found to be low, and the sulphates high. We have traced this to the discharge of pickling liquor wastes from a wire works.

Preservation of Samples.—The odor of samples of sewage, or purified effluents, is not recorded as a routine procedure. The reason is that the samples are collected over 24 hours for crude sewage, and over, 48 hours for other effluents. To avoid change in the chemical constituents, a preservative is added,—in our case chloroform to the amount of 10 c.c. to one gallon of sewage. The chloroform effectually hides any odor present, unless hydrogen sulphide occurs in large quantities. As an additional precaution, the samples are kept in cold storage up to the time of analysis.

Exhaustive study into the question of the preservation of sewage samples has shown us that, even in a storage period as short as 6 hours, perceptible changes will occur in the nitrogeneous constituents of a fresh unpreserved sewage. At room temperature, the addition of 10 c.c. of chloroform to one gallon of sewage checks the decomposition to some extent, but even in such cases, immediate analysis is often desirable to obtain accurate results. Cold storage alone is a fair preservative. The combination of chloroform and cold storage is the best obtainable method at present. An ideal preservative is lacking for liquids, like sewage, of changing character. It should be odorless and colorless, and should not affect any of the constituents present or interfere with the analytical determinations.

Suspended Matter.—During the various stages of sewage purification, it is important to observe the physical and quantitative changes in the suspended matter, since the aim to-day is to remove as much as possible at the outset, in order to obtain a fresh effluent. In studying the efficiency of a device, frequent determinations are necessary both for the influent and effluent, extending over a considerable period, before an opinion can justly be formed of the percentage removal of suspended matter.

The settling suspended matter should be clearly distinguished from the non-settling suspended matter, in studying the efficiency of a settling device. Much of the suspended matter in sewage, particularly on large areas, occurs in a finely divided, or colloidal state, not capable of sedimentation even on prolonged storage; hence, when a settling tank is removing perhaps 35% of the total suspended matter, it may actually be taking out 100% of the suspended matter capable of settling. On prolonged storage, however, some of the colloidal matter may coagulate, and material previously in silution will also change to apparent settling matter. This is particularly true for strong sewages. From our analysis of the composition of the settling and non-settling suspended matter, it is evident that the percentage if volatile matter is greater in the non-settling portion. This may have a very important bearing upon the true character of a settled sewage from the standpoint of a prospective nuisance in a stream.

The settled suspended matter is termed sludge. The percentage of volatile and fixed matter depends upon the character of the sludge, a fresh sludge containing more volatile matter than fixed matter, a septic sludge being higher in mineral constituents. The content of moisture may run from 85% to 95%, depending upon the device.

---

*Read before the Chicago Section of the American Chemical Society.

† Chemist and Bacteriologist, The Sanitary District of Chicago

Since the determination if the settling suspended matter is of importance in the control of a sedimentation plant, the daily variations may be advantageously followed by determining the loss of suspended matter on settling gravimetrically, or else by measuring the number of c.c. of settled matter in a conical-shaped glass holding one liter. Such glasses are used in Germany, and may be of value in dealing with strong sewages containing considerable amounts of settling suspended matter, but in our weak American sewages the control is not as satisfactory, since the 39th Street sewage, for instance, contains, on an average, only 140 p.p.m. of total suspended matter, of which from 40% to 50% is capable of settling. In our case, actual gravimetrical determinations are made of the total volatile and fixed suspended matters by the Gooch crucible method.

Sprinkling filter effluents contain, as a rule, some suspended matter, but of a different character from the original floating or colloidal matter. A sprinkling filter is not built primarily as a means of removing suspended matter, but as a machine to oxidize and mineralize the organic material delivered to it. In the long run, a sprinkling filter should deliver, in its effluent, nearly as much solid as received. At times the effluent may be very clear. Some observers claim that more is delivered. The effluent, however, is greatly improved from the chemical standpoint, and also from the standpoint of putrescibility. The suspended matter, when unloaded, may give rise to putrefaction if stored in considerable quantities, and may become septic, so that shallow secondary settling basins may change a non-putrescible filter effluent into a putrescible final effluent.

Oxygen Consumed.—The time-honored oxygen-consumed test indicates the amount of oxygen absorbed by the oxidizable matter during titration in acid solution with permanganate, and in particular the amount of organic carbonaceous matter present. At present there are so many modifications of the test, that the results from various laboratories cannot be directly compared, without knowledge of the method employed. In our laboratory the 30-minute water bath boiling method is used. For comparative purposes this is a valuable test, although the figures obtained do not represent anything absolute. The result covers only a small percentage of the total carbon. The organic carbonaceous compounds vary in their resistance toward acid permanganate solution. The average of the oxygen consumed in our sewage is about 50 p.p.m.; the average of the effluent of a sedimentation tank is about [illegible] p.p.m.; and the average from the sprinkling filter is about [illegible] p.p.m.

It is important to remember that the oxygen-consumed test does not represent the oxygen which the liquid would absorb under natural conditions in a water course. From the practical standpoint, a far superior test is one which in- [illegible]

Nitrogen.—[illegible]

the ammonia was converted mainly into nitrate, but if the living organisms in the soil were paralyzed by chloroform vapor, or other antiseptics, nitrification did not take place. For the activity of these organisms the presence of oxygen is essential, as well as of a base to neutralize the nitrous and nitric acid which is formed. Moderate temperatures are most favorable, but the action may take place even at temperatures as low as 3° or 4° Cent. Species have been isolated which require very little or no organic matter for their subsistence. Such bacteria seed themselves in biological filters, and nitrify or mineralize the material coming to them. In general, the larger the bacterial surface the greater the nitrification will be for a given application of liquid. The size of the material and rates of application have to be varied for the process attained. In an intermittent sand filter, only 100,000 gallons can be applied to an acre in a day, whereas in a coarse grain sprinkling filter from 2,500,000 to 3,000,000 gallons can be applied to an acre in a day. A sand bed 5 ft deep would give a much higher nitrification than a sprinkling filter bed 5 ft. deep of stone from 1½ to 2 in. in size, at the rates mentioned. Overloading a filter will interfere with nitrification. It is interesting to note how short a period is required to establish nitrification on a large scale. The nitrates represent the last step in the oxidation of the nitrogenous matter, and serve as food for the higher developed living organisms. These organisms, in dying, form the starting point of another nitrogen cycle.

As yet our understanding of the nitrifying organisms, and the processes involved, is very meagre, so that in the future, research will be desirable to learn the exact action taking place. Possibly the nitrification process can be intensified by artificial means.

Denitrification.—It is interesting to note that certain species of bacteria have the power of reducing nitrates to nitrites, free ammonia, and free nitrogen, in contradistinction to the nitrifying group. Grayson and Dupetit made the first observations in 1882, and concluded that denitrification was essentially the result of combustion of organic matter by the oxygen of the nitrates. Frankland and Beyerinck have added to our knowledge. Many organisms have been found which do not bring about denitrification.

Because of the research into the protein molecule, I wish to speak of the nitrogenous intermediate products, which in sewage disposal are frequently productive of disagreeable odors, as for instance indol, with its putrid odor, or ammonia, with its characteristic odor. Free nitrogen, as mentioned, is produced by the denitrifying action.

Significance of Nitrogen Cycle.—The nitrogen cycle offers a good index to the efficiency of a modern sewage filter of any kind. In a settling tank we do not expect much change in the nitrogen, except the elimination of some of the organic nitrogen in the settling suspended matter. In a more extended storage period the free ammonia may increase, and the nitrates and nitrites decrease, provided the sewage originally applied was not septic. In a septic tank the free ammonia ordinarily increases, and the nitrates and nitrites decrease, or become entirely eliminated. The increase in the free ammonia in a septic tank results from the reduction of nitrates and the breaking down of the organic nitrogen. The biologic treatment on sprinkling filters and sand filters is an oxidizing process, and should result in an increase of the nitrates and nitrites. The organic nitrogen is decreased in a filter, on account of the bacterial decomposition and the escape of the volatile nitrogenous products and free nitrogen proper.

Determination of Nitrogen.—The organic nitrogen, as well as the free ammonia, the nitrates and nitrites, are determined as a routine procedure on all our samples from the sewage testing station. The method for the determination of the organic nitrogen is that introduced at the

Columbus testing station, and consists in the digestion of the sample by concentrated sulphuric acid, subsequent neutralization and direct nesslerization. The free ammonia is distilled previous to nesslerization. Very often the sample is nesslerized directly after adding a few drops of potassium hydrate and copper sulphate, the resulting precipitate being allowed to settle. The nitrates are determined by the napthylamine-sulphanilic acid method, and the nitrates by aluminum reduction in alkaline solution.

Formation of Hydrogen Sulphide.—Another interesting topic in the chemistry of sewage is the formation of hydrogen sulphide, the history of the sulphur cycle resembling that of the nitrogen cycle. Its presence in sewage indicates putrefactive changes as a rule, since sulphur is an element of the protein molecule, and as such is always present in small quantities in sewage. Plants absorbing mineral sulphates convert them into organic sulphur. On breaking down, organic sulphur yields hydrogen sulphide which becomes oxidized again to sulphates, either by chemical or biological means. Just as nitrates can be reduced to free ammonia, so are sulphates capable of reduction to hydrogen sulphide. Apparently the sulphur cycle is influenced more by purely chemical reactions than is the nitrogen cycle, but in both cases the changes are largely the result of bacterial activities.

The principal question for further study is the generation of hydrogen sulphide from inorganic sulphates, since hydrogen sulphide is one of the constituents most intimately connected with the development of a nuisance, and may also be responsible for damage to concrete work. Practically all sewage bacteria will form the gas in artificial media containing sufficient organic sulphur. Any sewage containing hydrogen sulphide may form a black sediment typical of septic conditions, the sediment consisting mainly of ferrous sulphide, since iron is almost always present in sewage in varying amounts. Other gases, however, may originate from the destruction of organic sulphur, as for instance, mercaptan. The formation of hydrogen sulphide, however, from sulphates is of more importance perhaps than its formation from organic sulphur, since sulphates are often present in large quantities. The reaction is undoubtedly due to specific types of bacteria, rather than to a wide group. Beyerinck first noted the phenomenon, and stated that the best conditions for the reduction of sulphates were the absence of oxygen, the absence of sugar in the culture media, and the presence of phosphates and other suitable solids. Only small quantities of nitrogen compounds are necessary. The optimum temperature is around 25° Cent. Beyerinck isolated an organism, the spirillum desulphuricans, a strictly anaerobic organism reducing sulphates. Other important work has been carried on by Van Delden, Letts, and recently by Dr. Buchanan.

Significance of Hydrogen Sulphide.—Hydrogen sulphide in sewage may not only be responsible for a local nuisance, since amounts as small as 3 p.p.m. can be noted under outside conditions, but on discharge into a stream it will draw upon the dissolved oxygen present, and often to such an extent that fish life will be seriously interfered with. In addition, hydrogen sulphide by itself is a poison to fish. The reduction of sulphates has been observed in many sewages in the United States and abroad, particularly when the sulphates are high from the introduction of trade wastes. In some cases the disintegration of concrete has been a serious matter, due to the oxidation of hydrogen sulphide to sulphuric acid by the atmospheric oxygen.

One of our settling tanks, a modified Dortmund tank, or, as Professor Phelps calls it, a biolytic tank, affords a typical case of active sulphate reduction. At times as much as 40 p.p.m. of hydrogen sulphide have been observed in the effluent. This can be traced directly to bacterial activity.

Before dismissing this topic, I will mention the classic work of Winogradsky, who made an exhaustive study of the oxidation of free sulphur by higher bacteria, such as beggiatoa. The beggiatoa utilize the sulphur as a source of energy, taking up from two to four times their weight without increasing in growth. Requiring but small quantities of organic matter they flourish in sulphur springs, the decomposing hydrogen sulphide liberating amorphous sulphur. The sulphur in turn is oxidized to sulphates. The effluent of our biolytic tank is quickly oxidized in a sprinkling filter. The effluent of the filter, however, contains abnormally large amounts of sulphate, and the top of the filter is covered by a silk-like growth of sulphur bacteria.

In a sewage-disposal plant there is, as a rule, no occasion to test for hydrogen sulphide as a routine procedure. The sense of smell or a simple lead acetate paper test should suffice, unless some peculiar case requires special investigation.

Chlorine.—The chlorine in a domestic sewage originates largely from the urinary chlorine, and indicates approximately the strength of a sewage. It can be easily determined by direct titration with silver nitrate solution, using potassium chromate as an indicator. Except as an index to the strength of the sewage, the chlorine determination has no further significance. The presence of industrial wastes containing chlorine, or of ground waters or sea water, may prevent us from drawing conclusions. On an average, the sewage of 39th Street contains about 40 p.p.m. of chlorine, indicating a dilute sewage.

Alkalinity.—The alkalinity has little significance in the interpretation of results, since industrial wastes may cause abnormal figures. Sewage ordinarily is slightly alkaline, considerable quantities of acid waste being required in order to turn it acid in the sewer. The average alkalinity of our sewage is 220 p.p.m., calculated as calcium carbonate. We titrate our sample with 1/50 normal sulphuric acid. Methyl orange is used as in indicator.

Fats.—In domestic sewage the fats and fatty bodies result largely from the use of soap in laundries and from household wastes containing grease. On Monday there is a slight increase in the fatty content of our sewage, but the addition is not great, since on our watershed there is a large proportion of apartment houses where washing is spread over several days of the week. No attempt is made to separate the fat from the soaps. On the addition of sulphuric acid, a certain quantity of sewage is evaporated to dryness, and the total fat extracted with ether. The average amount present in our sewage is approximately 25 p.p.m.

Total Solids.—The total solids in sewage are not now determined as a routine procedure, being largely of scientific interest. In our case the amount is about 600 p.p.m., or 0.6 of a gm. per liter. This indicates the extreme dilute character of our sewage.

Dissolved Oxygen and Stability.—Dissolved oxygen and putrescibility will be discussed together, since while both are determined separately, neither is by itself as instructive as when studied in connection with the other. The two determinations not only furnish a key to certain phenomena in biologic sewage disposal, but when their relation is better understood the solution of many problems will be attained. In a popular sense, putrescible matter is material which draws upon the oxygen in solution for its oxidation. However, inorganic compounds sometimes utilize oxygen in solution for their oxidation as well. From the standpoint of sewage disposal by dilution, or in studying the effect upon fish life, it is immaterial how the oxygen is used up. During the colder season, fresh dilute domestic sewages contain, as a rule some oxygen which in a short time becomes exhausted, and anaerobic conditions set in. The liquid then enters a stage where oxygen is quickly absorbed when supplied in any form.

In the control of a sewage-disposal plant, the determination of the putrescibility is more important than the determination of the oxygen, and in comparison with the other constituents, the knowledge of the putrescibility or stability is of the greatest importance. With this test a plant can be controlled to better advantage than by any elaborate chemical analysis. The reason for this is simple. The ultimate aim of any disposal plant is to make the putrescible matter more or less stable. The putrescibility test indicates the degree of oxidation obtained, and the determination of the dissolved oxygen gives a fixed figure of the absolute amount available for further oxidation. Both factors are important in studying a nuisance or fish life. A high oxygen content, in itself, does not indicate stability.

Determination of Dissolved Oxygen.—In our laboratory, the Winkler method has been used to determine the dissolved oxygen in the manner described in the "Standard Methods of Water Analysis" adopted by the American Public Health Association. The sample is collected carefully in order to avoid aeration. Manganous sulphate and an alkaline solution of potassium iodine are then added. The precipitate of manganous hydrate is allowed to settle; sulphuric acid is then added, and the free iodine in the solution titrated with standardized sodium thiosulphate. The equivalent of free iodine is calculated to oxygen. The results are expressed either in p.p.m., or in percentage saturation. In the latter case the temperature must be considered. Normal fresh water which has not undergone temperature changes ought to be 100% saturated, but may be sub-saturated or supersaturated, depending upon conditions, such as the season of the year, the sunlight, the presence of algae, or sudden changes of temperature.

As an alternative method, the American Public Health Association has recently recommended the Levy method for the determination of dissolved oxygen. This consists, briefly, in the conversion of a ferrous salt into a ferric salt by the oxygen in the water. The residual ferrous salt is titrated with the permanganate solution. At present the use of either method is a matter of choice.

Determinations for dissolved oxygen should be made on the spot to avoid a loss of oxygen, particularly in putrescible samples. From a study of this question in our laboratory, we have concluded that only fresh saturated and uncontaminated water like that from Lake Michigan can be kept for a number of hours without showing a reduction in oxygen. Even then the sample should be kept in a cool, dark place. The addition of a small quantity of formaldehyde allows an extension of the storage period, but it is preferable to add the first two reagents in the Winkler method in order to form the precipitate, where the determination cannot be made on the spot.

Determination of Putrescibility.—The putrescibility test has been almost universally adopted by various sewage purification plants. The one most in favor is the so-called methylene blue test devised by Spitta and Weldert in Germany. A dilute solution of methylene blue is added to a definite portion of the effluent in a sterile bottle; the mixture is then incubated at 20° Cent. and the number of hours or days required to reach the blue color is discharged. This decolorization takes place only in putrescible samples, and [illegible] the formation of [illegible] the [illegible] by [illegible] has been [illegible]. Some prefer an incubation temperature of 37° Cent. to obtain quicker results, but this temperature is not [illegible] because it does not correspond to actual conditions, as does the temperature of 20°. Furthermore, a [illegible] will [illegible] at 20°, which [illegible] at the lower temperature. Phelps has [illegible] a [illegible] stability [illegible] the [illegible] of a sample can be expressed in terms of [illegible]. [illegible] figures [illegible] the proportion of [illegible] compared with the total amount required to effect the complete oxidation of a sample in question. The sample should be kept in the incubator for twenty days before being discarded, but from a practical working standpoint this is neither necessary nor desirable. Ten days storage as a maximum is sufficient, and often four days will give results sufficiently accurate for practical purposes. Samples which show signs of decolorization after four days may be held for further observation. The exact hour of decolorization is difficult to fix, but an experienced observer can avoid material mistakes in estimating the end point.

Index of Permissible Dilution.—The putrescibility test outlined is eminently practical and valuable, but is not a quick method. Recently Phelps devised another method to give the desired information in a shorter time. The test in principle is not new, for it has long been known that organic putrescible material will absorb oxygen in solution, and the rate of absorption under certain conditions has rightly been looked upon as a good index to the putrescibility of the sample. Only recently, however, could the permissible dilution be calculated for a sewage effluent under certain assumed conditions. The procedure is to mix a small quantity of sewage carefully with fresh aerated water in definite proportions, and to incubate the mixture at 20° Cent. for a number of hours. To hasten the result, the dilution may be lowered. The dissolved oxygen is determined in the mixture at the start and again after the lapse of several hours. With these two figures in hand, the percentage of sewage permissible in a stream under assumed conditions can be calculated. In the formula are terms for the period of contact and the percentage of dissolved oxygen to be available at the desired point in the flow. With our present knowledge of this test, the same assumptions must be followed from time to time in order to get comparable results, since the formula in its present state is not as perfect as may be, owing to the lack of knowledge of the shape of the curve for this bacterial reaction. The results obtained, however, are very practical and of great value. The method requires more accurate and careful work than the methylene blue test, and at present is open only to a skilled chemist.

Bacteria.—Most of the chemical changes in biologic sewage purification are in reality the result of bacterial activity. The significance of these bacteria in general is of interest largely from the scientific standpoint. The removal of disease-producing bacteria, however, is a question of practical interest. Sewage disposal devices, in themselves, are not built, primarily, as bacterial removers, and cannot be relied upon unless sterilization of the effluent with chloride of lime be added as a sure means for removing bacteria. In a chemical precipitation process, the bacteria may be reduced partly by sedimentation and partly by the germicidal properties of the chemicals employed. In a plain settling tank the reduction of bacteria is due to sedimentation. In a sprinkling filter or in a contact bed the reduction is undoubtedly the result of mechanical detention as well as the action of higher developed organisms. The unfavorable environment may also be an influence. Secondary settling basins will reduce the number of bacteria again by simple sedimentation. The effluent of a filter may contain [illegible] of the original number of bacteria present originally. Biologic sewage purification may eliminate the putrescible matter, but if bacteria purification be desired, disinfection only will secure the result.

In our laboratory the method employed to determine the number of bacteria is to plate 1 c.c. of the sample, properly diluted, on a litmus lactose agar medium. The temperature of incubation is 37°, and the time of incubation two days for the [illegible]. It is well known, however, that no artificial medium, be it an agar or a gelatine medium, will permit the growth of all bacteria ordinarily present. Therefore, the count per c.c. indicates but a portion of the true number. More colonies will develop on gelatine than on agar.

Methods of Sewage Disposal; Dilution, and Sedimentation.—I shall not attempt to discuss here the question of sewage disposal by dilution, other than to point out that such a method is entirely legitimate within the oxidation capacity of the body of water into which the sewage is discharged. I will, therefore, turn to a consideration of the methods of preliminary treatment which may be covered by simple sedimentation, decomposition, either aerobic or anaerobic, and chemical precipitation. In the operation of a sedimentation tank, sludge is removed frequently in the early stages of decomposition. The resultant improvement of the sewage from the standpoint of dilution will, of course, vary with the composition of the sewage and the amount of suspended matter present. We have recently demonstrated the fact that the simple removal of settling suspended matter improves the physical character of the sewage and its relative stability to some extent, but not to as great an extent as might be assumed from the actual physical improvement. In other words, the removal of 50 to 60% of the suspended matter will improve the character of the sewage from the standpoint of dilution from 25 to 30%. This means that the additional removal of the pseudo-colloidal matter will improve the liquid far out of proportion to the quantity of suspended matter thus removed. A device which would remove this fine suspended matter, without resorting to biologic treatment, would undoubtedly furnish an effluent which on a large scale would be intermediate between the preliminary or partial purification effected by settlement, and the more complete purification made by a sprinkling filter. In some cases it might suffice where preliminary purification alone would not.

Septic Tank.—The anaerobic decomposition of sewage finds its widest application at present in the septic tank. This process may also be called a hydrolytic or liquefying process, and is substantially the same as that in the ordinary cesspool. The cellulose decomposes, forming hydrogen and marsh gas. Carbon dioxide and fatty acids are produced as by-products. Nitrogen is formed, probably due to nitrate reduction. Thirty-two degrees Cent. is the optimum temperature for the decomposition of cellulose; therefore a septic tank shows more violent ebullition of gas during the hot season, and frequently unloads large amounts of suspended matter. In our climate not enough gas is produced for any practical purpose, but at Matunga, in India, the gas from a septic tank has been utilized for driving an engine to pump sewage and for lighting and cooking purposes.

The ammoniacal fermentation taking place in sewage is due to the presence of urea. It starts readily and is frequently completed in the sewer itself. In septic-tank treatment the protein substances are the ones responsible for the foul odors, since hydrogen sulphide, mercaptan, indol, skatol, and various amines result from their decomposition. Fats when present in appreciable quantities may give rise to an objectionable rancid odor.

It is still a question whether the decomposition taking place in sewage under anaerobic conditions, as in a septic tank, is an advantage in the further purification. Current practice favors the treatment of a freshly settled sewage. However, treatment of what may be called a "semi-digested" liquid has, apparently, some points in its favor, since compounds which are ultimately formed by these putrefactive processes yield more readily to oxidation than do the higher complex bodies originally present. On the other hand, the anaerobic decomposition products are probably inimical to the aerobic organisms present in the body of the filter.

Biolytic Tank.—In our biolytic tank, a remarkable reduction of the organic nitrogen has taken place, accompanied by the excessive formation of hydrogen sulphide. The pseudo colloidal matter has been completely eliminated, leaving nothing save a slight amount of black sediment and the hydrogen sulphide odor. All this occurs in less than four hours. Without further oxidation the effluent from this tank would be a nuisance, and a detriment from the dilution standpoint.

The chief objection to-day to the use of septic tanks is that they may produce a nuisance, and may discharge sludge in hot weather when the ebullition is a maximum. For these reasons the separate digestion of the settled suspended matter is recommended, particularly in double-deck tanks of the Emscher type.

The septicity of the sewage is a point worthy of comment. If we assume that hydrogen sulphide is the proper index of the increase in septicity, the formation of insoluble ferrous sulphide might be accepted as a measure, provided enough iron were present in solution to combine with all of the hydrogen sulphide. The key to the question probably lies in the bacterial control of the septic tank process, but a far deeper knowledge of the species involved is required than we possess at present.

Sludge.—Whether sludge be fresh or old, its ultimate disposal has been and still is a problem for sewage experts. In order to fully appreciate the difficulties encountered in the commercial utilization of the product, it is necessary to consider its physical as well as its chemical composition. Fresh sludge is a black semi-liquid substance with an odor varying from that of burnt rubber to an acrid putrid stink. The specific gravity varies 0.01 to 1.06. In our case the grit chamber sludge frequently contains considerable quantities of heavier material, and its specific gravity may be as high as 1.35. The average quantity of moisture is from 85 to 95%, the percentage of organic matter 60, and of fixed matter 40 when calculated on a dry basis, in fresh sludge. The nitrogen on a dry basis amounts approximately to 2%, the fat varying from 1% to 5%.

Many schemes have been suggested for the utilization of sludge as fuel, as filling for fertilizer and as material for gas, or even the manufacture of alcohol. Only in isolated cases under peculiar conditions has any process for the recovery of any by-products been successful. For instance in Bradford, England, where the sewage contains a deal of wash water from wool pulleries, fat has been successfully extracted from the sludge. The difficulty of the quick removal of the moisture from the sludge makes its use as a fuel doubtful. For the same reason drying the sludge for fertilizer purposes is uneconomical. Old sludge thoroughly digested contains much less volatile matter than the fresh sludge, the amount decreasing frequently from 60% to 40% of the total dry matter. In Germany and England, sewage sludge has been sold or given away to neighboring farmers, but the general experience has hitherto demonstrated the difficulty of disposing of sludge continuously in any such manner.

Partial purification of sewage can be accomplished under semi-aerobic conditions, as in a Dibdin slate-bed, which is akin to a contact bed. In this device nematode worms, infusoria, and bacteria accumulate and work over the sludge. Experience in this country with the slate beds has not been favorable.

Chemical Precipitation.—The colloidal matter in crude sewage may be eliminated by the use of chemicals as a precipitant. Ferric sulphate, aluminum sulphate, lime and ferrous sulphate have been frequently used in various combinations. The chemical to be employed and its quantity is largely governed by the composition of the sewage, and the cost of obtaining the chemicals. The quantity of sludge resulting is larger than from any other method of clarification. The effluent is low in suspended matter and is susceptible of treatment on filter beds at a high rate. Beyond a certain point, however, the application of chemicals does not reduce the amount of suspended matter appreciably. A concentrated sewage is better adapted to chemical clarification than a weak sewage.

Comparison of Methods.—More complete purification may be accomplished, either on intermediate sand filters, contact beds, percolating or trickling filters. The suspended and colloidal matter is mechanically retained by the filter material to be worked over by the biological life in the filter, which quickly forms in a new bed as a slimy coating on the surface of the particles of the filter material. The chemical change in the liquid is called nitrification or mineralization. When the bed becomes clogged, nitrification gradually ceases. In a sprinkling filter it is favored by the spraying of the liquid, which undoubtedly aids the oxidation process following. As a rule, more nitrates are formed in a sprinkling filter than in a contact bed, but less than in a sand filter.

The deeper the writer progresses into the field of sewage disposal, the more he realizes the amount of work that is still required to make it an exact science or art. The co-operation of biologists, entomologists, chemists, and sanitary engineers is required. The sanitary chemist is mostly concerned with the investigations of the biologic features, a thorough knowledge of which will materially aid in bringing about a better understanding of the facts already accumulated, as well as the solution of new problems. For the industrial chemist, the most fertile field for investigation is the ultimate solution of the sludge question. At present we are able to reduce the quantity of the sludge to a minimum, and to prevent offense, but we realize that certain constituents, even though small in quantity, may some day prove of commercial service. The economies to be obtained, however, will be available only in large plants where careful operation is possible.

PURIFICATION OF WATER BY STORAGE.

In a paper read before the International Congress on Hygiene and Demography, held in Washington, September 24th, Dr. A. C. Houston gave a discussion on the purification of water by storage. He stated that the purification of water by storage is discussed under three main heads: (1) Sedimentation; (2) Equalization; (3) Devitalization. The following comprise the chief conclusions so far arrived at:

(1) Storage reduces: (a) the number of bacteria of all sorts; (b) the number of bacteria capable of growing on agar at blood-heat; (c) the number of bacteria, chiefly excremental bacteria, capable of growing in a bile-salt medium at blood-heat; (d) the number of coli-like microbes; (e) the number of typical B. coli; (f) the amount of suspended matter, color, ammonical nitrogen and oxygen absorbed from [illegible]

(2) Storage alters certain initial ratios, for example (h), [illegible] the number of typical B. coli to a disproportionately greater extent than it does the number of bacteria of all sorts; [illegible] to a greater extent than those yielded by the permanganate test.

(3) Storage, if sufficiently prolonged, devitalizes the [illegible] and the cholera vibrio.

(4) [illegible] "equalizing" effect.

NATURAL GAS BELT IN WESTERN CANADA.

Some important finds of natural gas have recently been made in the Canadian West, within the limits of what seems to be a long, but narrow gas belt, running north and south, in the neighborhood of the 112th meridian. Mr. Aubrey Fullerton, in a recent issue of the "Mining and Engineering World," states that the latest strike was made in June at Tofield, near Edmonton, the capital of Alberta. At that point, after several borings had been made, a flow of gas was struck at a depth of 1,054 ft. The well was at once capped and the flow tested. It has since been gaining in volume, and gives every indication of being permanent, while the quality of the gas, for both lighting and heating purposes, is excellent.

Other towns in the surrounding district are arranging for borings of their own, in the belief that a great gas vein underlies the whole country. Indications of gas have been found at various times during recent years.

A great gas-tapping project is now under way at the southern end of this same belt, where the wells at Bow Island have been piped for a supply to the city of Calgary, 180 miles to the west. The pipe line, which was constructed by Corcoran & Co., of Pittsburg, has just been completed, and when the system is in full working order gas will be sold in Calgary at rates varying from 15 cents per thousand for the larger power consumers, to 35 cents for domestic use. The project represents a $3,000,000 investment.

The Bow Island wells are in the immediate neighborhood of Medicine Hat, whose natural gas system, now in use for some years, has made the town prominent. The town uses natural gas almost entirely for lighting and fuel, and an average householder's bill for both runs at from $20 to $30 a year.

In the northern section of the belt is the biggest gas well. The Athabasca River, for at least a good part of its course, runs through a country that seems to be underlain with gas, and a tract of 100,000 square miles is saturated with petroleum. At Pelican Rapids, at a point on the Athabasca River, 200 miles north of Edmonton, is a gas well that has been burning for fourteen years, and gives no sign of lessening in flow. A photograph taken last winter shows an immense gas jet whose flame is nearly 50 feet high, and of very substantial circumference.

The Pelican well was found in 1898, when the Geological Survey of Canada sent a party of oil-diggers into the north to see if the reported existence of petroleum was a fact. They got their outfit in over the wilderness trail, and set to work. When the drill reached a depth of 820 feet it struck gas. The flow was so great that it drove back the drill, and the noise of the escaping gas could be heard two or three miles away. After the survey party went away some one came along and lighted the jet, and it has been burning more or less continuously ever since.

The report to the Geological Survey in regard to the Pelican well recommended that a new bore at the depth of 820 feet, where the first large gas vein was encountered, "should be at least 10 inches in diameter; then it would be possible to reduce the casing four or five times, giving that many different lines of pipe to be used in getting by these gas veins." Meanwhile the search for oil was of necessity abandoned, and until the railroads get into the country there is little chance of the great natural resource being developed. The big gas jet is still blazing high and fiercely but wastefully, and a great coal area further north is similarly on fire, and has been for many years, burning slowly from within. The whole region is a vast depository of natural fuel. Oil oozes out along the shores of Great Slave Lake and the Mackenzie River, and tar drips all summer long from the banks of the Lower Athabasca and Great Slave Rivers.

FIELD SURVEYS FOR ROAD CONSTRUCTION.

At the American Road Congress at Atlantic City, Mr. E. L. Griggs, Associate Professor of Civil Engineering in the University of Georgia, presented a paper, which is reprinted below practically in full, in which he describes the methods of making the actual field surveys necessarily precedent to the proper construction of highways.

Before a survey of a road is made it should be known how the construction of it is to be carried out as that determines in a large measure how much engineering work should be done.

If the road is to be constructed by contract, and especially if the consideration is based on a price per yard of material handled, then justice to both parties to the contract demands a full and most accurate survey and determination of volumes.

While to take the other extreme, if a county is building its roads with its own labor, convict for example, much less engineering work may be done. The question of exact cost in this case is not so important and the determination of volumes is for construction purposes only.

Preliminary to the final decision of the location of a new road or, what is nearly equivalent, a radical relocation of an old road, a thorough study of all the feasible routes is essential. For this purpose a most useful instrument is the Plane Table or Traverse Table. We use the simplest form for this purpose which is 14 or 15 ins. square and weighs only a few pounds. With its aid all the probable lines are gone over and plotted, the distances being obtained with sufficient accuracy by pacing, while any determining features such as residences, roads, streams, etc., are triangulated in. Property lines crossed are also noted as bearing on the question of rights of way over the individual properties. A useful adjunct to the plane table in this preliminary study is a good hand level, with which comparative elevations of ridges, etc., passed over are very conveniently estimated and then noted on the map.

This work requires only one man for its execution and equipped with only these light instruments he can cover considerable ground in a day. If he is careful to make copious notes on the map it will show when completed not only the lengths and directions of the lines but also the character of the country over which the road would pass and the number of homesteads served. This latter is, of course, one of the really governing features of the final selection. This map also furnishes facts that will aid the engineer in answering the questions of the too persistent patron who has personal ends to serve.

After this preliminary work is completed and the final selection of the location is made then we are ready to actually stake out the road. If the road is to be constructed by contract then the regular work of a railroad survey should be done. The line should be carefully measured and staked, levels run and profiles made, cross-sections taken, slope stakes set and volumes accurately determined. All these operations are essential to a just settlement of the contract but they entail heavy engineering expenses.

In the State of Georgia, as in some of the other States, most of the roads are built by convict labor and here such reasons for great accuracy do not exist and quicker and more economical engineering methods may be used. For it is of far greater importance that a road should have easy grades, perfect protection from water and a good surface than that its curves, for example, should be theoretically correct. If a road is so located and graded that the material taken from the cuts will just make the fills why should we bother about the exact number of yards of material handled? Short sharp curves and quick reverse curves are both disagreeable and dangerous with rapid automobile traffic and are to be avoided.

In making our road surveys the road is staked out by a transit party in the usual manner of staking out a railroad location. The stakes are set every 100 ft. but on one side instead of the centre of the road so that they will not be disturbed in construction. Long curves are laid out in the usual method of deflection angles. Short curves, however, can be put in much more economically in point of time by setting the stakes over on offsets from the tangents. For instance, for a two-station curve the previous tangent is prolonged straight 100 ft. to the vertex, the angle with the forward tangent measured and the degree of curve decided upon. The stake at the vertex is then moved over on the curve. The distance the stake is moved over is equal to 1.75 ft. for every degree of deflection or 2 deg. of curve. For example, if the angle between the tangents is 16 deg., then the curve will be 8 deg., and the stake at the vertex will be moved over four times 1.75 ft., or 7 ft. The effect of this is to put the stake almost exactly on the curve, but the forward tangent will be found 0.6 ft. from the position it would have occupied if it had been laid out in the regular way, the curve shortened between 1 and 2 ft. from the recorded length, and the degree of curve slightly changed.

If, however, the central angle was larger and four stations of an 8 deg. curve decided upon, then the stakes at stations one and three would be set over 7 ft., while the stake at the vertex would be set over four times seven, or 28 ft., since the offset varies directly as the squares of the distance in 100-ft. lengths. That is, at station two the distance set over would be four times that at station one, and at station three, in a six-station curve, it would be nine times that at station one. Very little time, however, is saved in using this method for curves over 400 ft. long.

In the case of the four-station 8 deg. curve mentioned above the near half of the curve is almost exactly located while the forward tangent is again found away from its theoretical position, about 5 ft. in this case, and the whole curve shortened about 10 ft. from its recorded length. This difference of about 2½ ft. in one hundred will not affect the grade and it is also to be remembered that it is not cumulative but rather balancing. For if the curve is staked out on the outside of the curve and a centre line afterwards measured it will be found that the centre line to the point of tangency is still shorter than the curve as staked out. This will tend to balance when the curve is staked on the inside

Another very convenient method of laying out a curve and especially if one happens to be without his instrument, is one derived from the method given by Searles in his Field Engineering. At the point of curvature the previous tangent is prolonged 100 ft. further and perpendicular to it at its end in the direction of the proposed curve is laid off a distance equal to 1.75 ft. times one-half the proposed degree of curve for the first station of the curve. For the second station, and all succeeding stations, the line through the two preceding stakes is prolonged 100 ft. and perpendicular to it is laid off a distance equal to twice that for the first station or 1.75 ft. for every degree of curve. In order to get on the tangent at the end of the curve the line of the last two stakes is prolonged 100 ft. and the perpendicular laid off is equal to the one laid off at station one. For example, if we propose to use an 8 deg. curve the perpendicular laid off for the first station of the curve after leaving the tangent and for the first station on the forward tangent would be 1.75 ft. times one-half of eight, or 7 ft., and for all other stations it would be 1.75 ft. times eight, or 14 ft.

The transit party also determines accurately the location of the property lines crossed, so that the exact area of the right-of-way on each separate piece of property may be found.

After the line has been staked out the level party goes over it and stakes levels, the rod being held on the ground by the stake. Levels are also taken at the opposite side of the road, the width of the road being measured by pacing. Profiles are made of each side of the road approximately paralleling each other on the same piece of profile paper. This will give sufficient information to very closely approximate the balancing of the cuts and fills without the necessity of cross-sectioning. No slope stakes are set, as the cuts are usually light. The road bed is graded down to its proper depth and the banks afterwards shaped up.

We have sometimes carried out the whole operation of surveying a road with a party of only three men: an instrument man carrying a transit equipped with level tube and stadia hairs, a rodman carrying a self-reading level rod and a stakeman.

The instrument man, after he has set up his instrument and gotten his alignment, signals the rodman forward or backward until he is the proper distance away as shown by the stadia, then lines the rod in for the exact position of the stake. After this is driven he determines the elevation of the station by using his instrument as a level. As the distances are usually in hundreds of feet and the telescope horizontal no stadia notes will have to be kept or reduced. If the ground is practically level transversely no further levels need be taken, but if not the rodman must return, after going as far as the rod can be read, and hold his rod on the opposite side of the road. This method is very laborious and subject to errors by the instrument man overlooking some of his manifold operations and is suggested only for short pieces of work or when assistants cannot be had.

The stakes are of course numbered when set and if the foreman of construction is an experienced man he is simply furnished with a profile with the cuts and fills for each station written on it, or merely a list of the stations with the amounts of the cuts and fills. If he is not so experienced he will require considerable more supervision by the engineer.

Some may infer from what has been said that since certain approximations in the surveys are to be used, the services of the engineer may be dispensed with as unnecessary and the road located by the eye alone. Such, however, is very undesirable. The knowledge, judgment and experience of an engineer are always needed for the proper location of a road, and the responsibility should be his for grading the road and so balancing the cuts and fills, yet keeping within the limits of allowed grade, that the minimum amount of earth will be handled, and for placing proper culverts that the storm water may be at all times taken care of.

Experience has shown that the cost of construction is often very materially increased by not having proper grade stakes set beforehand. As an example, on one occasion in grading a hill, 6 ins. seemed enough to take off. So it was plowed to this depth and the dirt hauled to the next fill and the road shaped up. The grade still did not look right and [illegible] tions might have been gained if the road had been located [illegible]

TEMPERATURE EQUIVALENTS OF WIND VELOCITIES.*

By W. H. Whitten.

A comparison of records taken at the group of buildings of the Harvard Medical School on the total heat expended and average temperatures and average wind velocities showed that one mile of wind movement per hour required substantially the same amount of heat supply as one degree change in temperature. A further study of similar records, however, has shown that there is a greater proportion of loss due to wind movement as the temperature drops.

This led the author to make investigations as to the impact effect of wind of the same velocity at different temperatures. It was found that there is a regular rate of increase in effective pressure as the temperature drops, although the wind velocity remains constant. This regular rate of increase of pressure is maintained only while the barometer readings are normal. A barometrical change caused changes in the impact pressure. The exact rate of this change was not determined, but the fact of such change was detected, the tendency being for an increase in pressure as the barometer rose and for a decrease as it fell.

It was estimated that, with the barometer and the wind constant, the increase in pressure is 0.4 per cent. per degree drop in temperature. It was also found that the non-pressure or suction on leeward sides of buildings increased in about the same proportion. The point at which heat loss from one mile of wind movement per hour and temperature were equal seemed to be between 36 and 39 degrees above zero. Above this temperature, the effect of wind became less important than the temperature changes, and below it, correspondingly more important.

For example: If, at 37 deg. plus, one mile of wind movement per hour is equal to one degree drop in temperature, at zero one mile of wind movement per hour will equal

$$1 + (37 \times 0.004) = 1.148 \text{ deg.}$$

If the temperature increases to 50 deg. plus, then one mile of wind movement equals

$$1 - (13 \times 0.004) = 0.948 \text{ deg.}$$

As a rule for personal guidance, the author has adopted the following: From 40 to 15 deg. plus, one mile of wind movement per hour is equal to one degree drop in temperature; from 15 degrees plus to 20 degrees minus, one mile of wind movement per hour is equal to 1.15 degrees drop in temperature. This is for buildings constructed in the ordinary manner, that is, without protected windows. Applied strictly to the glass surface, with leakage standardized, the loss from wind movement may be calculated as only three-sevenths of the loss under usual and ordinary conditions. This not only applies to the sides having the so-called greatest exposure, but, owing to the suction or non-pressure existing on the sheltered sides, should be applied to all sides of the building.

SEWAGE DISPOSAL AND WATER POLLUTION.

This question was discussed at the meetings of the Great Lakes International Pure Water Association and the National Association for the Prevention of Pollution of Rivers and Harbors, which have just closed in Cleveland, Ohio. At these meetings Dr. Allan J. MacLaughlin repeated his opinions as recently given before the International Joint Commission at Ottawa, to the effect that to compel cities along the Great Lakes so to treat their sewage that it would not contaminate the lakes into which it is dumped, would place upon these cities an unnecessary and unjustifiable expense, which would bankrupt the cities in most cases.

Dr MacLaughlin's evidence as given before these bodies does not agree very well with some of his statements as they appear in a report known as Bulletin No. 83 of the United States Hygienic Laboratory, entitled "Sewage Pollution of Interstate and International Waters." There he states that "unfortunately, the Detroit River is so grossly polluted that the city of Wyandotte has suffered terribly from typhoid fever. Undoubtedly, Wyandotte and Munroe also should filter their water supplies and protect themselves, but they should not be required to treat a raw water, which puts an unreasonable strain and responsibility on their filter plant." Many other statements similar to the above might be quoted which make it rather hard to appreciate Dr. MacLaughlin's stand in his evidence before the International Joint Commission.

It is interesting to follow the reasoning used in the above mentioned bulletin. He states that with the present rate of discharge of the St. Lawrence River Lake Ontario would require over six years to empty itself if all inflow were stopped, and then he adds that this means that the water in Lake Ontario is capable of purifying an enormous amount of organic matter, and that with the existing pollution the water should be pure outside of the zones of polluted water which surround the water-front of cities and towns and the mouths of large rivers.

The zone of pollution is a most uncertain one, as has been well demonstrated in the vicinity of Toronto. Prevailing winds may force the area of sewage-polluted water many miles from its ordinary boundary. Thus, the benefits of six years' storage of water in Lake Ontario are rather minimized. Dr. MacLaughlin states that the pollution by the Niagara River, including the sewage of Buffalo, the Tonawandas and Niagara Falls (together with the Canadian towns) is subjected to natural purifying agencies in its passage over the Falls and through the river. The results of bacteriological examinations show that the pollution at Niagara-on-the-Lake is a great deal higher than at Buffalo or Lake Erie. The effect of the Niagara River as a purifying agency is practically negligible, for it is only a matter in time of about twelve hours for water to pass from Lake Erie to Lake Ontario.

While it is true that the danger of sewage pollution of Lake Ontario is minimized by the depth of the lake and its enormous capacity for storage, at the same time it must be recognized that Lake Ontario is becoming constantly more infected. In the very near future, some experts say immediately, means must be taken to treat the sewage of the cities on the Great Lakes and the rivers flowing into them. Therefore, since this is true, the sooner the control of pollution of the Great Lakes is placed in the hands of the International Joint Commission the better it will be, in the ultimate, for both countries.

MATHEMATICS AND THE ENGINEER.

Theory and practice, in the minds of most engineers, have not a proper relationship. It is too commonly accepted by the profession to-day that a distinct line must be drawn between the purely theoretical man and the practical designer and constructor. We often hear the statement made that theory is all right, but practice and experience are the safest in the long run. As a matter of fact, there is no line to be drawn between theory and practice.

It is true that it is hard to analyze the strength of any engineering structure by means of mathematics without a practical knowledge. At the same time, it will be readily admitted that the progress made in engineering design and construction during the past few years has been due to the application of mathematics in the analysis of the stresses in their component parts.

In an address delivered by Sir William H. White, at the recent International Mathematics Congress held at Cambridge, another view of the utility of mathematics to the engineer is given. No one knows, he pointed out, any method by which the strength of a ship can be settled à priori, by deduction from the results of laboratory experiments on the physical constants of the materials used in its construction. All that is possible in getting out the scantlings of a ship, of larger size than ordinary, is to take as a model a ship which experience has proved to be of satisfactory strength. This is treated as a girder loaded in a hypothetical and purely arbitrary fashion. The stress which would result from this load is calculated, and a similar hypothetical load is then applied to the proposed vessel. Should the calculation show that this calculated, but wholly hypothetical, stress is not greater than in the model, the scantlings are considered satisfactory. The whole process, in fact, amounts to little more than an application of the rule of three, and experience shows that in this instance the procedure is legitimate. In fact, in a great number of cases we can find by mathematical methods the relative strength of two structures; but mathematical methods afford us generally no data as to the absolute strength of either. Indeed in certain cases, they fail even to indicate fairly the relative strength of similar members of different materials. Some years ago, for instance, the purchaser of a large testing-machine had considerable difficulty in persuading the builders of a well-known type to supply him with one having a steel beam. They wished to supply cast-iron, and submitted calculations which represented the latter to be not only stronger than the proposed plate-steel substitute, but stiffer. In the end, however, they gave way, but supplied their cast-iron model to another customer, with the result that it broke in seven pieces some eighteen months after being put into service. Taking a narrow view as to the field occupied by theory, it would be permissible to maintain that there was here a serious discrepancy between theory and practice; but, although it is not possible to express in mathematical form the difference in the reliability of a tough and of a brittle material, the difference cannot be neglected in any theory that claims to be in any way complete.

Mathematics to a great extent has been responsible for the benefits of our present day civilization, and it will always be the basis for engineering design. Mistakes have been made, and will continue to be made, not through the use of mathematics, but through the use of wrong assumptions on which the mathematics are based.

MONTREAL HARBOR COMMISSION

The announcement of the resignation of Major George Washington Stephens from the position of chairman of the Board of Harbor Commissioners of the port of Montreal brings to its end a Commission which has appeared to shipping and commercial circles of Montreal almost ideal. The resignation of Major G. W. Stephens came shortly after those of his two fellow-commissioners, and to some extent was no doubt occasioned thereby. Mr. Stephens makes that fairly clear in his letter of resignation, in which he refers to the manner in which the three Commissioners always worked in harmony, and expresses the view that harmony of that character is essential to the effectiveness of a commission. He considers, therefore, that it is best to retire and give the government an opportunity of electing an entirely new commission.

Part of the success of the commissioners and the cleanliness of their administration was no doubt due in large part to the fact that none of them were in financial need of the appointment. The chairman is a millionaire, and the financial remuneration attached to his position was of little consequence to him, and would be largely exceeded by the cost of maintaining the position. Messrs. Ballantyne and Geoffrion are wealthy men, and would also make more money attending to their own businesses.

The post of chairman of the Commission is one which demands the highest type of executive ability and imaginative power.

The government can only be praised for the appointments made to the chairmanships of the Transcontinental Railway Commission in Mr. R. W. Leonard, and to the International Joint Commission in Mr. C. A. McGrath. The action of the government in the selection of a new Gommission will be awaited with much interest. It is to be hoped the choice of a chairman will fall on a man of engineering training and of the requisite administrative capacity.

◆

TRINIDAD ASPHALT MINING.

The consumption of Trinidad asphalt, mainly for street construction and in a minor degree for chemical and other purposes, increases from year to year. The bulk of it is recovered from the pitch or asphalt lake on the island situated on elevated ground about fifteen miles from the sea shore. Smaller quantities are recovered by open pit mining in the close vicinity of the lake, where various deposits have accumulated from overflows in prehistoric times. The lake covers about 40 hectares, and is very deep; its surface is solid and hard enough to carry people. The asphalt is cut off with large hoes; the pieces so recovered are carried by hand into trucks attached to cable trams, and removed to the sea shore for export. A comparatively small portion of the output is, previous to being exported, freed from its water contents in a refinery on the island. The crude asphalt represents a brownish-black mass with a peculiar smell; it contains about 30 per cent water, 30 per cent mineral substances, and the rest is bitumen. The bitumen averages 82 per cent C, 10.5 per cent H, 6 per cent S, and 1 per cent N. The yearly export has now reached about 180,000 tons. Of late a liquid asphalt, or rather a highly asphaltic mineral oil, has been recovered on the island and exported, after the elimination from it of the liquid oils. It is particularly suitable for softening the hard Trinidad asphalt. The natural generating and hardening processes, which have ultimately resulted in the production of the asphalt, are of a very complicated nature; sulphur seems to have played a conspicuous part in them in conjunction with oxidation and polymerisation processes.

COST OF WATER SOFTENING BY LIME.

The members of the Metropolitan Water Board, London, England, have recently issued a pamphlet under the title of "Eighth Report on Research Work," by Dr. A. C. Houston, and a perusal of its contents would leave an impression that this board had spent considerable time since the issue of the seventh report on the financial economics of softening and sterilization of water and of the effects of time on bacteriological and pathogenic organisms when treated with germicidical agents of varying strengths.

(10,000 gallons=100,000 lbs.)

Temporary hardness of water as carbonate of lime, or its equivalent in soap destroying power, parts (or lbs.) per 100,000 parts (or lbs.) = lbs. per 10,000 gallons (100,000 lbs).	Cost of quicklime (10 lbs. 2¢.) and the amount to be added to soften the water.					
	Theoretically, that is 1 lb. of carbonate of lime requires ·56 lb. quicklime.		Practically, that is assuming that from ·75 to 1·0 may actually be required (owing to free CO_2 inert lime, &c.)			
			BASIS 1. 1 lb carbonate of lime requires ·75 lb. quicklime.		BASIS 2. 1 lb. carbonate of lime requires 1 lb. quicklime.	
	lbs. lime.	cents.	lbs. lime.	cents.	lbs. lime.	cents.
1	·56	·112	·75	·15	1	·2
2	1·12	·224	1·50	·3	2	·4
3	1·68	·336	2·25	·45	3	·6
4	2·24	·448	3·00	·6	4	·8
5	2·80	·560	3·75	·75	5	1·0
6	3·36	·672	4·50	·9	6	1·2
7	3·92	·784	5·25	1·05	7	1·4
8	4·48	·896	6·00	1·2	8	1·6
9	5·04	1·008	6·75	1·35	9	1·8
10	5·60	1·120	7·50	1·5	10	2·0
11	6·16	1·232	8·25	1·65	11	2·2
12	6·72	1·344	9·00	1·8	12	2·4
13	7·28	1·456	9·75	1·95	13	2·6
14	7·84	1·568	10·50	1·1	14	2·8
15	8·40	1·680	11·25	1·25	15	3·

The method of softening water with lime may be explained by the following equation:—

Bicarbonate of lime.		Quick lime.		Carbonate of lime.		Water.
$CaO, CO_2 H_2O, CO_2$	+	CaO	+	$2 CaO, CO_2$	+	H_2O
100 62	+	56	=	218	+	18

Fifty-six parts of quicklime (CaO) are required to combine with 62 parts of hydrated carbonic acid (H_2O, CO_2), holding the 100 parts of carbonate of lime in solution. As the hardness of a water, however, is expressed in terms of carbonate of lime, 0.56 part of quicklime is required to precipitate 1 part of carbonate of lime.

In practice considerably more quicklime is required, because the free as well as the combined carbonic acid in the water has to be acted upon and, in addition, part of the quicklime (CaO) may have become hydrated (CaO, H_2O), and therefore less active weight for weight, and part may be inert (carbonate or impurities), and, further, the mixing operations may be imperfect.

The free carbonic acid, of course, is a constant factor, for all degrees of hardness, which it is sought to remove.

The accompanying table shows the working cost of softening 10,000 gallons of water with quicklime, irrespective of interest on capital expenditure, depreciation, labor, etc., and is based on a price of $4.80 for a ton of lime. Lime in this country is somewhat higher, so that this must be allowed for.

The cost remains the same whether quicklime or slaked lime is used, but the above weights of quicklime must be multiplied by 1.32 to obtain the comparative effective weights of slaked lime.

The above results are expressed as parts (or lbs.) per 100,000 parts (or lbs.), which is the same as lbs. per 10,000 gallons. To convert into grains per gallon and "degrees" of hardness, multiply by 7 and divide by 10. No account is here taken of permanent hardness, which requires a different kind of treatment for its removal.

The wastage of lime due to free carbonic acid being a constant factor, the figures in the last two columns are only approximately correct—thus the wastage at 1 and 15 (due to CO_2) being the same, it is proportionately cheaper to soften to 15.

To take an example:—A water has a total hardness of 21, the permanent hardness being 7 and the temporary hardness 14. It is required to soften 10,000 gallons from 21 down to 11 (i.e., 10 parts). The amount of quicklime required would be, theoretically, 5.6 lbs. (costing 1.12 cents), but practically about 7.5 (costing 1.5 cents) to 10 lbs. (costing 2 cents) would be needed. Erring somewhat on the side of exaggerating the cost, it may be said that 10 lbs. of quicklime, costing 2 cents, would be needed to reduce the total hardness from 21 down to 11 (10 parts) for every 10,000 gallons of water treated.

◆

A NEW BRONZE.

The great strength necessary for bronze used in the construction of machinery, the keen competition existing between manufacturers, and the wide fluctuations in the price of tin, have induced metallurgists to study the question of substituting for the rather expensive tin bronze some special brass compositions (so-called zinc-bronzes) which not only have the advantage of being cheaper, but also surpass the tin bronze, so far as the breaking strength and elongation quality are concerned, at the same time offering the same resistance to attacks by acids.

The fact that despite the aforementioned advantages claimed for zinc bronzes, tin bronze still obstinately keeps its ground in most of the large foundries and in nearly all the minor ones, is unquestionably due to rather serious drawbacks, which even the best zinc bronzes, so far known, present along with their above-mentioned advantages.

The principal drawbacks may briefly be summarized as follows:

These zinc-bronzes generally have a very complex composition, mostly containing addition of metals not easily fusible and which unite only with great difficulty. On account of these two features the preparation of the alloy can only be carried out in a very complicated and expensive way, often even necessitating the separate preparation of distinct compositions, so-called "preparatory alloys."

The zinc-bronzes have a strong tendency toward separating when cooling down in the mould: the so-called "sweating" (liquation) takes place, which destroys the homogeneity of the smelted metal, the splitting tendency of which increases, whereas its chemical stability greatly suffers.

It is obvious that metal additions, which have to be forcibly dissolved, either by resorting to preparatory alloys or to incessant mixing before casting, take advantage of the first opportunity to separate, which opportunity presents itself during the solidification of the metal in the mould, or, in other words, during the period when a regular development of the process is of utmost importance.

*In accordance with the requirements as adopted by the fifth International Congress for the testing of manufacturers products and materials, the said congress held at Copenhagen in 1909.

Furthermore, all zinc-bronzes contain iron, manganese or aluminum, and most of the time the compound of these three metals. These additions cause the formation of an oxide scale on the surface of the smelted metal; this scale or pellicle is indestructible and is continually being formed anew even if every precaution is taken in cleaning off the surface. This pellicle may also be carried in the mould, where it is constantly formed afresh; it often gives rise to troubles by intruding into the casting in the form of slag incrustation or superficial impurities.

Another and perhaps the most important drawback attached to the best zinc bronzes known to date is the fact that they shrink considerably when cooling down, bringing about a tendency to form flaws (blow-holes) in the castings.

As the result of numerous series of systematically conducted researches, the foundry laboratory of the engineering works of Escher Wyss and Company, Zurich, Switzerland, has succeeded in producing a new bronze, which, besides being one of the best [illegible] compositions, [illegible] breaking strength and tenacity, without presenting the disadvantages outlined above.

[illegible]

At the engineering works of Escher Wyss and Co., at Zurich, Switzerland, and at Ravensburg (Wurtemberg), this new bronze, "Universal Bronze," has been used on a large scale for several years in the manufacture of any kind of machinery parts exposed to heavy and sudden stresses, such as wedges, bearings bushes, valves, stuffing boxes, screws, screw heads, wings of screw propellers, runners for turbines and turbo-pumps, etc.

Particularly in the construction of turbo-pumps for raising impure water or acids, the employment of "Universal Bronze" has been a success. This bronze has proved to resist the wear and tear of these liquids in a way so far unknown. "Universal Bronze" may also be forged, rolled, stretched and bent in cold condition, whereby its qualities of resistance are being considerably increased (see table). The low price should particularly be noted as same is considerably cheaper than ordinary tin bronze (4c. per lb.)

A few co-efficients of resistance obtained at tests made with "Universal Bronze" are stated in the attached table. As to the resistance to stresses produced by shock by testing the flexure on a notched bar (the results obtained are stated in the table in the last column), it should be noted that these tests have been carried out in accordance with conditions agreed upon by the fifth congress for testing materials held at Copenhagen in 1909. The figures obtained in the annexed table, therefore, cannot be compared with those based upon testing methods by Charpy, Fremont or Guillery.

◆

INDUSTRIAL ACCIDENTS.

According to the record of industrial accidents maintained by the Department of Labor, that for the month of September shows there to have been [illegible] workmen killed and [illegible] injured, a total of [illegible]. Compared with the record for August, this is an increase of one fatal and 114 non-fatal. The trades and industries in which the greatest number of accidents occurred were: Steam railway service, in which there were [illegible] fatal and [illegible] non-fatal; metal trades, with 3 killed and [illegible] injured; mining, with 10 killed and 42 injured, and the building trades, with 10 killed and 33 injured.

WINTER TROUBLES ON ELECTRIC RAILWAYS.*

By Charles J. Jones.

The operation of electric railways in sections of the country where there is little or no snowfall, differs but little from the regular performance at other seasons. Where the winter is a rainy season of a few months the problem becomes one of railway construction, requiring waterways of sufficient number and capacity and properly located so as to avoid breaks in the roadbed due to washouts. In our northern districts, where the snowfall is of some importance, the question of maintaining the schedule in winter becomes at times a difficult one and a source of anxiety. Snow, sleet, ice and frost are the trouble makers, and the manager who contends successfully against them is the one who has made full preparation before the winter had made its appearance.

The maintenance-of-way department should see to its waterways and bridges. Where pile bridges are maintained over streams, such tools and explosives as may be necessary to protect the supports from ice should be on hand and ready for use. Heaving of track by frost is a menace to the safe operation of trains, and is a frequent cause of delay to the service. It seems almost impossible to obviate this trouble entirely, but as it is usually the result of poor drainage, it is important that all ditches in the cuts should be cleaned before the frost comes. Certain cuts cannot be drained properly by the ordinary ditch, and it then becomes necessary to lay drain tile a few feet below the ditch in order to draw away the moisture from the subsoil.

Sleet and ice coupled with high winds are serious factors to be considered in the proper maintenance of transmission lines and the assurance of a continuous supply of power. Poles and cross-arms should be carefully inspected and strengthened where necessary; new insulators should replace doubtful ones, and all wires (telephone, trolley and transmission) should be looked over and the weak places made strong. On lines where the third rail takes the place of the trolley wire, the same careful inspection should be made and proper attention given to the insulators, underground cables (with the necessary drainage thereof) and the cable terminals. The loss of power for a short time during the progress of a winter storm may mean the loss of train service for many hours.

The handling of snow may be considered under two heads: 1, Methods of preventing snow from accumulating; 2, Methods of removing snow.

Methods of the first class as applied to interurban lines include the widening of cuts and the use of snow fences. Where trouble from snow drifts occurs annually, a permanent board fence may be erected in place of the usual right-of-way wire fence. Frequently we use boards nailed to the regular fence, supporting them by nailing to the fence wire and to an intermediate post. Portable snow fences may be set out in the fall and removed in the spring. These are usually made in panels about 16 ft. long and 6 ft. high, and should be set from 50 to 100 ft. from the track.

As a rule, landowners do not object to allowing these fences on their land, but in some cases compensation is demanded. A wise forethought while securing right-of-way, has in some instances provided for the right to use portable snow fences on the adjoining property, and where possible this should always be done. These fences cost about 25c. per lin. ft., and when properly placed are extremely valuable in preventing the snow from drifting into the cuts. As the snow piles up around them, these fences can be raised on the drifts or set farther back as occasion warrants.

There seems to be no reason why the usual wire right-of-way fence should not be replaced in places subject to snow drifts by hedges of osage orange, honey locust, Japan privet, tartarian honeysuckle, or other hardy growth, which could be kept trimmed to fence height. In addition to acting as a partial protection against drifting snow they would make a permanent right-of-way fence, neat in appearance and effective in preventing cattle from passing through.

Methods of the second class, referred to as the "removal of snow" are various. They include many devices, from the man with the shovel to the light rail scraper and the powerful mechanical plow. The man with the shovel is not to be disregarded, as he is an essential factor in any snow-fighting equipment. His limitations, however, are apparent to anyone who has attempted to clean snow from track with a hundred and more men in the face of a gale of wind, the air dense with drifting snow and the temperature about zero. He no doubt has felt not only the effect of exposure to the storm, but also that of discouragement when, upon looking back, he has found that the section just cleared from snow was again full.

On city lines it is usual to equip the cars with scrapers, which are under the control of the motorman and so arranged that the blades are held on the rail under pressure. On all unpaved streets and highways it is important that the mud and dirt should be scraped aside and leveled down before it becomes frozen. If this is not done, the scraper will not be able to reach the rail and the motor and gear casings will be dragging on the high places.

The rotary broom sweeper is used especially on city lines and, being very effective, should be included in the snow-fighting equipment of all companies operating cars on streets and highways. These sweepers may also be equipped with wings which push the snow beyond the range of the brooms. As the sweeper throws a cloud of snow it is important that it should be operated by men of good judgment, as the flying snow is very likely to frighten horses. The electrical equipment to operate these sweepers varies according to the ideas of the purchaser, but the mistake of having slow-speed motors to drive the brooms should be avoided.

On lines operating on private right-of-way in the open country the high-V-shaped nose plow and centre-share plow prove to be highly efficient. These plows also are equipped with adjustable side wings to push the snow farther aside. These types of plows practically force their way through the snow and the secret of their success is weight of car and high speed. They should have the speed of the fastest passenger car on the system, in order to be able to run ahead of the regular cars and keep clear of them, and also for the purpose of clearing a large track mileage. The writer has passed through snow drifts varying from 2 to 10 ft. deep and 2,000 ft. long with a snow plow of the centre-nose type built on a flat car 34 ft. long (50 ft. over points of plows), with wings open to clear a width of 11 ft. It was weighted down with rails and old iron; equipped with four 125-h.p. motors, and geared to a speed of 72 miles per hour.

Passenger, freight and express cars are frequently equipped temporarily with a small nose-plow attachment, and are able to cut their way through snow that otherwise would stop them. In sections where the snow conditions are severe, the rotary snow plow is much to be desired. This type of plow has a large pan or hood in front, with spreading wings to collect the snow as the car is driven forward. Within the hood is a revolving wheel fitted with blades which cut the snow and carry it upward, throwing it a considerable distance to the side.

The movement of cars through snow soon forms a crust which becomes harder as the motor casings continue to drag on it. This hard centre not only checks the speed of the cars, but causes a loss of power in proportion to the extent to which the casings ride on it. This condition becomes at once apparent if a car having smaller wheels than the others is run over the line. When such a car comes to the hard centres it soon stops, and efforts to move it brings only spinning wheels. Upon examination it is found that the motor casings are riding on the crust of snow and raising the wheels from the rails, destroy the traction effort. To remove this hard centre we have the scraper and flanger, which is usually lowered and raised by compressed air. In some cases a device with steel points arranged in the form of a tooth harrow is used successfully to break down the hard centre. In congested terminals and streets where the snow can no longer be pushed aside by the wings of snow plows, etc., it becomes necessary to load it on wagons or cars and haul it to the most convenient place for unloading.

---

* Abstract of a paper read before the Illinois Electric Railways Association.

Snow storms vary in intensity and in kind, and it is hardly possible to depend upon a single type of snow plow or sweeper to overcome them all. Certain types of plows are better adapted to control certain storms. To have at command any or all of the above mentioned snow-fighting devices is not alone sufficient; there must be organization for the work. The organization should be carefully planned in advance and the men included therein fully instructed and trained, so as to avoid confusion or misunderstanding when the emergency arises. Men trained to a particular work of this kind should be kept there, if possible, as experience is a valuable asset. The men should be instructed to report for duty immediately upon the first snowfall and be ready to take charge of the work allotted to them. The superintendent or officer in charge should be where reports of progress or difficulty can reach him promptly, so that he can act in accordance therewith with precision. The work must be started with the appearance of the storm, without waiting until reports come in of the cars being stopped.

Having an organization and equipment, it is also important that the equipment be thoroughly overhauled and put in condition for immediate service at the beginning of winter. When the threatened danger has made its appearance, there is no time for repairs or the purchase of shovels and brooms or plows. A contest against the storms of winter is war, so let us follow the adage "In time of peace, prepare for war."

◆

SURFACE OILING AND CONSTRUCTING OIL MACADAM.

The city of Oakland, Cal., has been employing heavy asphaltic road oil on its macadam construction so as to make it suitable for light traffic under modern conditions. A description of the methods employed in this work and the results obtained were given by Mr. Wm. J. Baccus, commissioner of streets, of Oakland, in a paper presented at the [illegible] Munici-palities, held at Berkeley, Cal., September 23 to 28. Mr. [illegible]

Surface Oiling Methods.—Our methods of surface oiling [illegible]

square yard gives the best results. This oil is then covered with fine, clean screenings already at hand in the gutters, sufficient to prevent the oil from running into the gutters or adhering to passing vehicles. The street is then rolled with the steam roller and thrown open to traffic. It has been the custom in the past to allow the oil to stand for one or two days before screening, with the thought that the irregularities in the application will disappear, but this has several objections, and it is no longer necessary since we have adopted the use of the pressure oiler. The method described is applicable only to streets in fairly good repair. If so badly worn that half of the street must be covered with rock to produce a uniform surface, it is doubtful if the results will justify the expenditure. In such cases it is now our practice to scarify the street, harrow, reroll and reconstruct as oil-macadam, the oil having a penetration of two or three inches.

Surface Oiling Cost.—Our costs have varied between 5 and 12 cts. per square yard for ordinary surface oiling on different streets. Assuming that the street is in fair condition, and eliminating the cost of patching ruts and holes, which is not properly chargeable to oiling, a cost of 6 cts. per square yard should not often be exceeded. This does not include office expenses or general supervision. This assumes about ½ gal. of oil per square yard. More oil adds to the cost directly by the cost thereof, and indirectly by increasing the amount of screenings that must be used.

Following is a statement in detail of oiling several streets recently in Oakland, aggregating about .7 mile and having an area of 11,738 sq. yds. These streets were hard and smooth and in a hill section of the city:

	Total.	Per sq. yd.
6,000 gals. oil at 4.38 cts. (delivered)..	$263.12	$0.0224
160 yds. screenings at $1.75 (delivered)	280.00	.0238
3 days steam roller at $15.00..........	45.00	.0038
Oiling—		
District deputy 2 days at $5.00.....	10.00	.0009
Sub-foreman 5 days at $3.00......	15.00	.0012
Labor, 25 days at $2.50............	62.50	.0053
Cleaning Street—		
Deputy, ⅔ day at $5.00..........	3.33	.0003
Sub-foreman, 2 days at $3.00......	6.00	.0006
Labor, 10 days at $2.50............	25.00	.0021
Cart and driver, 2 days at $4.00 per day	8.00	.0007
Total	$717.05	$0.0611

Or about 6 1/10 cts. per sq. yd.

Results From Surface Oiling.—To make clearer the significance of these figures, apply them to a certain group of streets, comprising one sprinkler route in another part of the city. This route is also in a hill section and comprises 4.26 miles, besides a number of blocks not sprinkled because already oiled. The average daily cost for sprinkling is $3.68 for water and $5 for driver, horses and carts, a total of $8.68 per day. Allowing 250 days per year, the annual cost for sprinkling is $2,170. The estimated cost [illegible] twice per year, together with special cleaning of culverts and gutters during and after storms, is [illegible] would be [illegible] the streets were oiled. The total saving, on these two items alone, of sprinkling and cleaning, would be $2,170, plus [illegible] office expense and general supervision. The estimated cost of oiling being about 72,240 sq. yds. at 6.1 cts., is $4,407. Therefore, if the oil surface lasts on the average one year eight months over the district, the expense of oiling this sprinkler route is justi- [illegible] Other routes, on [illegible] less, would not [illegible] the oiling, while others [illegible]

Patching is done intermittently on macadam streets, at such intervals that we have no satisfactory figures on cost per mile per year. Patching on oiled streets must be done systematically and more frequently, because the public demands a smoother surface on an oiled street. Therefore, until more definite figures are obtainable, we must assume that there will be no decrease in the cost per mile per year for patching as a result of surface oiling, but that the same amount of money, or a small increase, will give better service. The saving will appear in lessened wear and tear on vehicles and greater convenience to the public.

Oil Macadam: Methods.—Our method of constructing oil macadam, summarizing briefly from our specifications, is as follows:

After the roadway has been brought to the proper subgrade . . ., and after the curbs and gutters have been constructed, a layer of broken stone, having a depth varying regularly from 8 ins. at the centre of the roadway to 6 ins. at the gutters, measured before rolling, shall be spread on said sub-grade. . . . The aforesaid layer of broken stone shall then be covered with a layer of screenings of sufficient depth to fill the voids in said layers of broken stone, and then thoroughly rolled with a 10-ton roller until the screenings have worked down into the broken stone and the roadway presents a uniform surface. All depressions occuring in said roadway during the rolling shall be brought to the required grade with broken stone and screenings of the same size and quality as is used in the aforesaid layers.

The aforesaid broken stone and screenings, after being thoroughly rolled and before the rolled surface has been disturbed, shall then be sprayed uniformly with oil at the rate of 1 gal. to the square yard of roadway surface covered, and allowed to remain in this condition for a period of not less than 48 nor more than 72 hours. A light layer of screenings shall then be spread over this oiled surface, after which the roadway shall be sprinkled with water and thoroughly rolled with a 10-ton roller.

The roadway, prepared as hereinbefore specified, shall then be allowed to become thoroughly dry, after which oil is to be sprayed uniformly over the surface at the rate of ½ gal. to the square yard of street surface covered. Screenings, to the extent of preventing the oil surface from adhering to vehicles shall then be dusted over said oiled surface and thoroughly rolled.

Oil shall be applied to the pavement under pressure of at least 30 lbs. per square inch. . . .

All of the above-mentioned oiling shall be done only while the atmospheric temperature is above 65° Fahr., and even then only during such periods as the sun is shining. No oiling will be permitted when the layer of broken stone or the screenings are in any way wet.

The oil is a residuum of an asphaltic oil and contains 85 per cent. of asphalt, having a penetration of 80. The temperature, volatility and allowable impurities are specified in detail.

Good workmanship and materials are necessary to secure results. In general, it may be said that the same precautions must be observed as for plain macadam, with several that are special to this work. Dirt, and dust in quantities, must be excluded. The greatest difficulty, and one that requiries experience and judgment to overcome, is in securing that amount of penetration that will use all of the oil (that is, take the surplus from the surface) and yet allow enough near the surface to produce finally an asphaltic appearance. The kind of rock and screenings used, the amount of screenings, the amount of rolling, the moisture present, and the weather are all conditions that must be considered. In general, it may be said that the voids should be well filled and the stone compacted before the first oil is brought on the work, but the surface should be quite porous, even open. After the first oiling should come the greater part of the rolling. In fact, before the second oiling the street should be as thoroughly compacted as can be done with a roller weighing at least 250 lbs. per lineal inch of tread. In some cases there has been a tendency to reduce the amount of rolling below the requirements of plain macadam. This should not be permitted. Oil macadam requires fully as much rolling as plain macadam.

In some places we have used and are planning to use more extensively in the future, a better class of oil macadam. This is constructed in two courses. The first consists of 4 or 5 ins. of ordinary macadam sized rock, screened, rolled and practically completed as for plain macadam. Then we spread 3 ins. of rock, not exceeding 2 ins. in size, and proceed much as already described in detail. We try to confine the penetration of the oil to the second course.

With neither type of oil macadam, nor in fact, with surface oiling, do we try to secure a uniform asphaltic appearance immediately upon completion. If we should, the material would adhere to passing vehicles and we would find it necessary to spread more screenings. It requires several weeks or months, and in some cases a year, for the surface to assume its final appearance.

Oil Macadam: Cost.—We have no figures showing the additional cost of constructing oil macadam over and above the cost of constructing plain or water-bound macadam, except such as can be deduced from our experience in surface oiling and from a comparison of contractors' bids. Roughly we figure that oil macadam, constructed as already described, costs from 1½ to 2 cts. per square foot more than plain macadam. Perhaps it would be fair to say that comparison of bidding prices shows an average increase of about 15 cts. per square yard. For oil macadam complete, as described, we are paying this season from 8¼ cts. per square foot to 9¾ cts. per square foot, or from 74 to 88 cts. per square yard. These prices, of course, include the contractors' profits, cost of collection and all overhead expenses. Where the pavement is constructed in two layers, the cost is increased again about 12 or 15 cts. per square yard. Two-layer work being better in all classes of macadam, this further increase, of course, is not chargeable to the use of oil.

Before closing this paper, it might be well to explain our reason for using oil macadam on new construction and on reconstruction instead of the cheaper process of surface oiling. As already indicated, the results are more permanent. If it be necessary to restore the asphaltic coating of oil macadam after the lapse of several years, it can be done with even less expense than original surface oiling on plain macadam. A mere surface of oil is removed within a period varying from two to five years by the action of traffic and storm water, but these agents seem to have little effect on oil macadam except at the surface. Furthermore, it is claimed, on proof of experience, that surface oiling frequently encourages raveling by preventing the renewal of the moisture that is so necessary to preserve macadam. Theoretically this should be particularly true of streets oiled soon after construction before traffic has secured final compaction. This difficulty should not be observed where the upper half or more is bound with oil. Furthermore, we have found it extremely difficult to secure a surface of oil that will adhere to the macadam and that will not "roll" or "wave." Every precaution must be observed to have the street clean and to adjust the quantity of oil to the requirements of the street. With oil macadam, however, we have more latitude within reasonable limits, for if the street finally shows a deficiency of oil at the surface, the fault can always be corrected by a light third application.

In conclusion, it may be said that it is our policy to permit the use of standard asphalt pavement on light traffic streets, but not to urge such construction excepting near the business district; to use oil macadam on all new construction in the residence districts; to surface oil, as rapidly as funds permit, all plain macadam streets that are in condition to be treated economically; and to reconstruct with oil macadam all plain macadam streets whenever such streets become worn out, unless conditions require a better pavement.

◆

AMERICAN ROAD BUILDERS' ASSOCIATION.

Arrangements for the American Good Roads Congress and ninth annual convention of the American Road Builders' Association at Cincinnati, O., December 3rd, 4th, 5th and 6th, have been practically completed. The plan adopted last year of considering certain specified subjects each day will be adhered to this year, although a somewhat greater subdivision of the main topics has been made. The first session, on Tuesday, December 3rd, will be devoted to the usual addresses of welcome and responses, and a presidential address by Nelson P. Lewis, Chief Engineer of the Board of Estimate and Apportionment of New York city, and president of the American Road Builders' Association. Six of the seven remaining sessions will be devoted to the presentation of technical papers and their discussion, and one session will be used for the annual business meeting of the Association.

The tentative programme of the technical sessions includes three papers on the organization of highway departments of States, large cities and small cites, respectively. The first will be presented by Major W. W. Crosby, Consulting Engineer of the Maryland State Roads Commission; the second by Wm. H. Connell, Chief Engineer of the Bureau of Highways, Philadelphia, Pa., and the third by a speaker yet to be announced. The development of a plan for a State or county road system will be treated in a paper by an authority yet to be announced, as will also the construction of stone and brick pavements. The building of earth and gravel roads will be treated in a paper by Robert C. Terrell, State Commissioner of Public Roads of Kentucky. The subject of bituminous pavements for cities will be presented in a paper by George W. Tillson, Consulting Engineer of the Borough of Brooklyn, New York city, and Ellis R. Dutton, Assistant City Engineer of Minneapolis, Minn., will describe the construction of wood block pavements by the day labor plan now in force in that city. Three papers on questions of importance to all engaged in either road or street work will be presented by Col. Wm. D. Sohier, [illegible] of the Massachusetts Highway Commission, who [illegible] Clifford Richardson, Consulting Engineer, New York city, who will [illegible] Arthur S. Lewis, Secretary and Superintendent, Lincoln Park Commission, Chicago, Ill., who will discuss the value [illegible]

[illegible]

OPERATING RESULTS OF IMHOFF SEWAGE TANK.

The Imhoff sewage tank at Winters, California, has now been in operation for over four months and the operating results were described by Mr. Fred H. Tibbetts, designing engineer, in a recent paper before the League of California Municipalities. The design of the tank is similar to other Imhoff tanks previously described in this journal, especially those at Chambersburg, Pa., and Winchester, Ky. A brief description of the structural features of the tank at Winters is here given, however, to aid in the interpretation of the operating results later described. The information is abstracted from Mr. Tibbetts' paper.

Features of Design.—The sewage disposal works at Winters were designed to accommodate a population of 3,000, which is twice the present number, so that no enlargement of the work will be necessary in the near future. The estimated daily sewage flow is 75 gals. per capita, 225,000 gals. for the assumed population of 3,000. There are two tank units with sludge digesting chambers capable of storing six months' sludge production. The chambers are 20 ft. in diameter and have an effective depth for storing sludge of 6.5 ft.; the sludge capacity amounts to 1,950 cu. ft. for each tank or a total of 3,900 cu. ft. Estimating the amount of sludge at 0.007 cu. ft. per capita per day, the amount from 3,000 persons, therefore, would be about 3,780 cu. ft. in six months.

Communication between the upper and lower chamber of each tank unit is afforded by 10-in. slots. The trough bottoms slope toward the slots at an angle of 45 deg., which is assumed to be steep enough to allow the solids which settle on them to slide down and pass into the sludge chamber. The sewage as it enters the sedimentation tank passes under two scum boards set 1 ft. apart, with their lower edges 18 ins. below the water surface. These intercept floating matter and if the scum forms back of or between the boards it may be removed by raising the planks which cover this space. The arrangement at the outlet end of the tanks is identical with the inlet and provision is made for reversing the direction of flow periodically so as not to get a greater accumulation of sludge in one tank than in the other. The bottom of the sludge digesting chamber is an inverted cone with a height of 5 ft. and a diameter of 20 ft. The depth of sewage will be such that the sludge at the bottom will be under 19 ft. of water.

When the sludge is being removed water may be discharged into it from five points to stir it up and make it slide down to the intake of the sludge pipe. Around the base of the vertical walls of the beginning of the bottom slope is a 2-in. water pipe for flushing. There are four 1-in. openings spaced around the tank at 90 deg. intervals and a branch running to the lowest point of the tank.

Sludge is removed from each tank by an 8-in. outlet pipe of cast iron coated with coal tar to protect it from the action of the sewage. The intake end of this pipe is at the lowest point of the sludge chamber and the discharge end is in a square concrete manhole 5 ft. below the sewage level of the tank and is fitted with a shear gate. When this gate is opened the sludge will be forced into the manhole from the bottom of the sludge chamber by a 5 ft. head of water and from here will flow by gravity to the sludge drying bed.

The tanks are covered by a reinforced concrete roof [illegible] ins. thick, high enough above the sewage surface to allow the formation of a sludge mat. Manholes [illegible] ins. at the side and [illegible] ins. at the centre of each tank are provided for removing this mat if it becomes necessary to do so. All parts of the roof of the sludge chamber slope to some one of these three manholes, so that the gas bubbling from the working sludge will have free passage to the vents.

A 10-in. galvanized iron pipe connects with each of the three gas chambers and extends 10 ft. above the roof.

To give complete control of operation a 2-ft. concrete channel to carry the sewage runs entirely around the tank and is provided with stop planks, so that the sewage may run through both tanks in reverse direction, through the first tank only or by-pass both tanks. The major part of the sedimentation takes place in the first tank and it is proposed to reverse the flow through the system every week or so in order to equalize the accumulation of sludge. If it should prove that one tank is sufficient for the present population to be served, the second tank may be by-passed and held in reserve until needed. The tanks are located near the site of a proposed public park; for this reason it was considered advisable to cover them.

Operating Results at Winters.—The Imhoff tanks at Winters have not been in operation long enough to give very definite ideas of what may be expected of them, as they were first put into service about four months ago. The operation has been under the supervision of Mr. Luke Gregory, who, although without experience in sewage disposal, has given unusually careful and intelligent supervision. Three progress reports have been obtained from assistant engineers since that time, but no analyses have been attempted. The last inspection was made on September 20, by the writer, in company with Mr. Gregory. The system is completed, but all the houses have not yet been connected and the amount of domestic sewage delivered is much less than that for which the tanks were designed. The effluent from the tanks has been quite clear and comparatively free from solids, except at times some finely divided black humus matter. At first, while the flow was very small, a slight odor might be detected, but this appears to be hardly perceptible at present. During the greater part of the period of operation, only one tank has been in use. Lately a part of the sewage has been diverted so as to enter the outer end of each unit, being taken off at the centre opening. This makes the tanks operate in parallel rather than in series, as was intended.

Bacterial action is decidedly active, as evidenced by the continual rising of large quantities of gas bubbles. Most of these bubbles rise in the centre manhole, which collects gas from the largest portion of the sludge wells. Although gas was escaping in large quantities no odor of hydrogen sulphide could be detected, even close to the open manholes. The heaviest mat was found in the centre manhole of the first tank. This was about 6 ins. thick, the manhole being 3 x 4 ft. All of the other floating solids would probably be not more than six more cubic feet, making in all about 12 cu. ft. of floating solid material in the entire tank. This is a very small quantity compared to the amount of material usually found in the floating mat of a septic tank, and indicates that a large proportion of the solids do not hold enough gas to keep them continually floating.

The mat was similar to that usually found on a septic tank, and when judged by the odors given off was not nearly so offensive. Some of the material from the lower part of this mat was taken out and examined. It consisted of a black homogeneous mass containing very little fibrous material and having little odor other than that suggestive of tar or crude oil. The mat on the side manhole of the first tank was but about 2 ins. thick, similar in appearance to that in the centre. Bubbles were rising here also, but in not nearly such large quantities as appeared in the centre. This was due also in part to the fact that most of the solids fall nearer the centre of the tank, after passing through the slots from the sedimentation chamber.

The sludge deposited in the bottom of the tank has been measured by Mr. Gregory, who found it to be about 2 ft. thick. No sludge has yet been drawn out. Since the capacity of the sludge well permits of an accumulation of something over 6 ft. before this will become necessary, no observations on the character of the sludge from the bottom have yet been made.

It was found that a slight mat had formed on the sedimentation chamber longest in use. This mat was very thin, probably not over ½ in., and its origin has not been definitely ascertained. The slope of the partitions between the sedimentation chamber and the sludge wells is 45 deg., or 1 on 1. It may be that some finely divided solids have remained on this surface for a period long enough for putrification to set in and have bubbles form, causing them to float. Or it may be that, as was observed in the Philadelphia experimental tanks, some solids are contained in the sewage, which are light enough to float of themselves. Gas and scum is so small compared to the amount of sewage passing through that it cannot be a serious defect. Later designs of Imhoff tanks call for slopes of 1 on 1½ for these surfaces, and perhaps with such steeper slopes there would be less tendency for scum to form in the sedimentation chambers.

As will be noted from the description, a cover was placed on the tanks. This was done in spite of the fact that both Dr. Imhoff and Dr. Rudolph Hering of New York considered it unnecessary. In general, a cover is, undoubtedly, not required. The writer, however, believes it better to cover any sewage disposal works operated in close proximity to residences, as there is undoubtedly less odor in any type of works which is covered. At Winters, the pipes arranged for conduction of the gas from the tanks have been brought together and extended so that the point of discharge is now about 30 ft. above the ground. The operator states that previous to this there were, on quiet mornings, objectionable odors in the immediate vicinity of the tanks. This condition was relieved upon the extension of the pipes. The effluent has been concentrated in a closed iron pipe and taken down to the creek bed, where it flows through a channel in the gravel for a distance of about 100 ft. to the main stream of the creek, which is very low at this season of the year. The only odors noticeable about the entire plant were in the 100-ft. channel through the gravel. This could be readily eliminated by diverting the flow of the creek so that the point of discharge of the tank would be under water.

The cover has been found efficient in preventing the use of the tanks as a breeding place for mosquitoes, and the operator has found it desirable to make all openings as nearly tight as possible except for the gas pipes and effluent pipes.

During the summer months a large amount of cannery waste, estimated by the operator as high as 150,000 gals. in 10 hours, was discharged into the sewers, and found its way to the tanks. This material is strongly alkaline from the use of lye in the fruit canning process. It is stated by the operator that upon its arrival at the tanks, sludge decomposition as evidenced by the formation of gas bubbles, ceased. Also that the velocity of flow through the tanks was too high to admit of thorough sedimentation, and that at such times objectionable odors were given off and the effluent was dark and contained considerable suspended solids. Normal action was quickly resumed, however, when the cannery wastes were diverted from the disposal works.

◆

TO UTILIZE LUMBER REFUSE.

Vancouver sawmill owners propose to utilize lumber refuse now being consumed in huge burners at the mills to make electrical power and steam heat, and to offer the same for sale. Application is made to the civic authorities for the necessary permission to lay wires and pipes for transmission purposes. The movers in the scheme say they can offer electricity to the city at ¾ of a cent or one cent per kilowatt.

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

BOOK REVIEWS.

Artistic Bridge Design.—A Systematic Treatise on the Design of Modern Bridges according to Aesthetic Principles. By Henry Grattan Tyrrell, C.E., Bridge and Structural Engineer. Chicago: The Myron C. Clark Publishing Co. Cloth; 6 x 9 in.; 294 pages; 242 figures (about 80 full-page half-tones). Price, $3.00 net.

Reviewed by C. R. Young, B.A.Sc., Consulting Engineer.

Although several comprehensive discussions of bridge æsthetics have appeared in the transactions of the great engineering societies and as chapters in general treatises on bridge design, Mr. Tyrrell's book is the first one in English, as far as the reviewer is aware, to be given over entirely to the consideration of this subject.

The author's purpose, as disclosed in the sub-title, is a commendable one, and, broadly judged, he has treated the subject well. Such criticisms as a careful reader may make are largely those of detail, and cannot be said to challenge the value of the book as a whole.

After a splendidly-written introduction by Mr. Thomas Hastings, of Carrère & Hastings, the well-known architectural firm, of New York, the author justifies his choice of subject by showing the importance of bridges, their effect on civilization and progress, and the necessity for artistic bridge construction. He then proceeds to establish "Standards of Art in Bridges," stating and discussing the following five —

1. Conformity with environment.
2. Economic use of material.
3. Exhibition of purpose and construction.
4. Pleasing outline and proportions.
5. Appropriate but limited use of ornament.

In the fourth chapter, which, it would seem, in the interests of logical arrangement, should have preceded the one just mentioned, the author effectively sets forth the "Causes for Lack of Art" in bridges. Chapter V., entitled "Special Features of Bridges," is given to the consideration of bridges carrying buildings, memorial arches, towers, etc., [illegible] it has been made to include [illegible] the [illegible] general [illegible] of the kind of bridges from the stand-point of the material employed and the selection of the [illegible] "Principles of Design" are elaborated in Chapter VI., [illegible] the "Standards of Art" [illegible] in Chapter III. In Chapters VII. to XI., inclusive, are discussed the various [illegible] illustrations, [illegible] a full page each. On the page facing each illustration is a brief description of [illegible]

[illegible] that

"there is no greater jar to æsthetic feeling than to see a bridge in which this principle (symmetry) is violated with large spans at one end and smaller spans at the other, or with the principal span noticeably out of centre" is scarcely supported by reference to an elevation of the Walnut Lane bride at Philadelphia. Lack of symmetry is, of itself, not a source of disappointment if the reason for it is distinctly apparent and does not arise from sub-aqueous conditions. Nor is disappointment occasioned if a part of the bridge is obscured from view, or if the bridge is so large that the whole structure cannot be seen in elevation at any one time. Again, the alleged necessity of indicating in some way on the surface the absence of spandrel filling where spandrel curtain walls are used (p. 22) is not defensible if the arch ring is accentuated in proportions consistent with a spandrel-filled arch. It might further be pointed out that the three designs for girder bridges by the author, shown on pages 51 and 52, are not wholly free from the defects which commonly mar such structures. In two of them the abutments lack face batter, thus giving an impression of instability; in all of them an even, rather than an odd, number of fascia panels are employed; and in one the turned balusters are large enough to effectually dwarf the girder itself.

There is a certain looseness of expression in portions of the book, indicating undue haste in writing. For example, the author speaks of certain buildings being "adorned with art" and stone bridges displaying "an amount of art . . ." Trusses are said to resist bending "by the counteracting moments in the upper and lower chords."

One regrettable feature of the book is the paucity of references to the work of those who have done most to shape and define the aesthetic principles which the author is able to re-state, possibly in improved form. Of the fourteen foot-notes, twelve refer to the work of the author and two other sources of information. The critical reader will scarcely believe that the division of honors in the references bears a proper relation to the division of labor in the development of the subject.

Apart from these and certain other criticisms which might be made, the value of the book is unquestionable and everyone who is responsible for the design of bridges should own, or have access to, a copy.

The Metallography of Iron and Steel.—By Albert Sauveur. Published by Sauveur & Boylston, Cambridge, Mass. 450 pages; size, 7½ x 10½; fully illustrated. Price, $[illegible], post-paid.

Reviewed by T. R. Loudon, B.A.Sc., Metallurgical Engineer.

Metallography has in the past few years received a great deal of attention in the literature of the day. One would not be [illegible] in saying that more attention has been devoted to the metallography of iron and steel than to any of the other metals, and, indeed, it is only to be expected that this would be so when the complexity of the composition of iron and steel is taken into account, together with the commercial importance of iron and steel. It is readily seen, however, that the very fact that a great deal has been written on the subject constitutes the main difficulty that is encountered by the student or the engineer who wishes to get authoritative opinion along these lines, and who, not being a specialist on the subject, has not very definite ideas where to look for information. The need for an up-to-date treatise on the metallography of iron and steel has long been felt.

In view of the above mentioned state of affairs, it is not surprising that such an authority as Professor Sauveur should undertake to compile a work on the metallography of iron and steel.

Professor Sauveur's book is divided into twenty-four lessons, a list of which is given at the end of this review; a chapter on the apparatus of the metallographic laboratory, and two appendices on the manipulation of apparatus and the nomenclature of microscopic constituents. The illustrations throughout are very clear; this being particularly true of the microphotographs of the various specimens. To anyone at all familiar with the photographing of metallographic specimens this will be keenly appreciated. Only too often is good subject matter spoiled by blurred microphotographs that convey no real idea of actual conditions.

It might be pointed out that the system of dividing the book up into Lessons instead of Chapters rather detracts than adds to the value of the book. There is, perhaps, rather too much of the academic suggested, whereas really the book is written with a good, practical style. Then, also, the numbering of the pages by the Lesson, i.e., beginning anew at each Lesson instead of consecutively from the beginning of the book with an ordinary index, is certainly not a time-saver.

In Lesson No. I. on Pure Metals, the author very clearly points out the difference between crystalline growth and the formation of grains. The term crystalline grains as applied to grains resulting from crystallization is a good one.

In Lesson No. 5, page 12, under the heading Micro Test for the determination of carbon in steel, the statements made are perhaps a trifle misleading. It is said that, "after a little experience and by taking the necessary precautions it will be found that, in the case of decidedly hypo-eutectoid steels at least (steels containing, say, less than .6 per cent. carbon) results are obtained fully as accurate as those of the colorimetric method, and on the whole more reliable, since the possibility of serious errors is practically eliminated." Undoubtedly the author refers to steels that are supposed to be homogenous in composition. Even admitting the value of the microscope in determining carbon content, the great trouble is that such a determination merely holds for the surface examined—the steel one-eighth of an inch below this surface may be, and often is, of a different carbon content. By chemical means, however, drilling being taken, a better average is obtained. Of course, one must admit that serious errors do often occur in colorimetric determinations, but these are mainly due to lack of skill. The same applies to the microscope. One cannot agree with the author that "after a little experience" carbon contents can be estimated. It requires a good deal of experience. As a check the microscope is invaluable, but should be used very guardedly in making determinations of carbon content.

In the investigation of the effects of mechanical and heat treatment on steels, the practical value of metallography is at once seen. This is undoubtedly the great field for metallography. In Lessons XI. to XIV., on the mechanical treatment, annealing and hardening of steel, Professor Sauveur has given a very thorough presentation of the subjects. The illustrations show very clearly the effects of the treatment to which the specimens have been subjected. These portions of the book form a valuable practical piece of scientific literature.

Lessons that should be at the end and not the beginning of the book seem a trifle strange. One can make very little real progress in the metallography of iron and steel before understanding the equilibrium diagram of iron and carbon. Be this as it may, it is pleasing to note that Professor Sauveur takes the stand that in iron carbon alloys above about 1.7 per cent. carbon, the eutectic formed is that of austenite and cementite, and that any graphite that may be found subsequently, results by the breaking up of the cementite into ferrite and graphite. This is surely the more practical way of treating the subject. The explanations of the iron-carbon diagrams are very clear, the points of historical interest being very neatly worked into the subject.

The entire book is a valuable addition to scientific literature. The book can be said to contain everything pertaining to the metallography of iron and steel written from an ardent metallographer's point of view.

The following is a detailed list of the Lessons in the book: Pure Metals, Pure Iron, Wrought Iron, Low Carbon Steel. Medium High and High Carbon Steel, Impurities in Steel, The Thermal Critical Points of Iron and Steel, Their Occurrences, Causes and Effects (three Lessons), Cast-Steel, Mechanical Treatment of Steel, The Annealing of Steel, The Hardening of Steel, The Tempering of Hardened Steel, Theories of Hardening of Steel, Cementation and Case-hardening of Steel, Special Steels (two Lessons), Cast-Iron, Impurities in Cast-Iron, Malleable Cast-Iron, Constitution of Metallic Alloys, Equilibrium Diagram of Iron-Carbon Alloys, The Phase Rule, and two Appendices mentioned before.

Theory of Structures.—By R. W. Angus, B.A.Sc., Professor of Mechanical Engineering, University of Toronto. Published by the Engineering Society, University of Toronto. Cloth; size, 6¾ x 9¼ in.; 232 pages, 147 figures. Price, $3.00.

The full title of this volume is the "Theory of Machines, Including the Principles of Mechanism and Elementary Mechanics of Machinery." The book is intended as a text-book for students in engineering in the University of Toronto. The subjects treated in the chapters are: The Nature of the Machine, Motion in Machines, Velocity Diagrams, The Motion Diagram, Toothed Gearing, Bevel and Spiral Gearing, Trains of Gearing, Cams, Forces Acting in Machines, Crank Effort and Turning Movement Diagrams, The Efficiency of Machines, Governors, Speed Fluctuations in Machinery, Proper Weight of Flywheels, Accelerations in Machinery. The method of determining the velocities of parts of machines, used in the volume, is called the phorograph method, and is here published for the first time. This gives a convenient graphical method for determining accelerations, kinetic energies of links, etc. The whole matter covered in the treatise is presented in readable form, and is very clearly written. To the student or engineer interested in the study of the theory of machines the book will be of considerable assistance.

Modern Organization.—By Charles DeLano Hine. Published by The Engineering Magazine Company, N.Y. Cloth; size, 5 x 7½ in.; 110 pages. Price, $2.00.

This volume is the latest addition to the Works Management Library, issued by The Engineering Magazine Company, and is the first complete statement of Major Hine's theory and practice of "unit organization" that has been put forth. The unit system applied on the Harriman lines has been remarkably successful in promoting efficiency without causing trouble. It is peculiarly interesting, because it seems to involve so little physical change and to depend so completely upon the apparently subtle, but after all, very direct internal improvement that is brought about when the official is given a new viewpoint of his work and its relation to co-ordinate departments. The system establishes a third mode of bringing line direction and staff guidance into co-operation, a mode essentially different from either Emerson's efficiency staff or Taylor's functional management

The chapters assembled in this volume appeared originally in The Engineering Magazine as a series of articles, which ran from January to July, 1912. The volume forms a comprehensive definition of this philosophy of management, and forms a valuable addition to Efficiency Management textbooks.

Energy and Velocity Diagrams of Large Gas Engines.—By Paul L. Joslyn. Published by the Gas Engine Publishing Co., Cincinnati, O. Cloth; size, 6 x 9 in.; 70 pages, 62 diagrams. Price, $2.00.

The designer of large gas engines has to consider many things which on small engines are often left to be worked out after the engines has been built in its first form. With small engines it is not so expensive or so difficult to change some points, and it frequently happens that very radical changes in construction are so effected. But with the engine of several thousand horse-power it is impossible to do this. So far as can be done, everything must be worked out in advance. Castings and machine work run into a large amount of money on engines working on blast furnace gas, and to scrap a cylinder or a bed casting because some change is found necessary may amount to several thousand of dollars in initial expense, manufacturing cost, delays, etc. In this book, the author gives the methods of laying out energy and velocity diagrams for large engines operating on blast furnace, producer or natural gas, with instructions as to their use, etc. The data given is the result of actual designing of this character on some of the largest engines built in American and Europe, and will be found of inestimable advantage to the designer working on engines of this character.

Central Station Heating.—By Byron T. Gifford. Published by Heating and Ventilating Magazine Co., New York. Leather; size, 5½ x 9 in.; 208 pages.

Central Station Heating during the last three or four years has received a great impetus, and a new era in this branch of engineering is rapidly dawning. With the increased attention and interest it has become desirable that the engineers interested in this department of engineering design should have the existing data on the subject presented in concrete form. Central station heating in its broader sense is properly classed as a public utility, and will eventually be controlled by the different utility commissions. As the development of these plants increase the field for them will become larger. Many of the elementary principles of the science of heating have been omitted, but [illegible]

The Materials Used in Sizing.—[illegible]

[illegible]

Handbook for Highway Engineers.—By Wilson G. Harger and E. A. Bonney. Published by McGraw-Hill Book Co., 239 West 39th Street, New York. Size, 4 x 7 in.; 500 pages. Price, $3.00.

This admirable publication is divided into two parts:—
Part I. Theory of Design.
Part II. Practice of Design and Construction.

The authors are men actually engaged on roadwork, and are, therefore, in a position to state clearly and well the subject matter of the text.

The publication contains the information ordinarily used in the design and construction of roads warranting an expenditure of from $5,000 to $30,000 per mile.

The information is presented in a compact and convenient form, and in addition to a table of contents there is a complete index.

It is a book valuable to experienced and inexperienced road-builders alike.

The cost data furnished is a valuable contribution to the literature on road-making, but the table and lists of quantities is if anything more useful.

The following questions are dealt with in logical sequence: Grades and Alignment, Pavements, Surveyors, Estimating, Construction, Specifications, and in addition the book contains sixty-seven tables.—E.A.J.

Concrete Highways.—Published by the Association of American Portland Cement Manufacturers, Land Title Building, Philadelphia, Pa. Paper; size, 6 x 9 in.; 95 pages. Profusely illustrated; free.

Every person interested in the good roads movement is aware of the latest development in this important work through the use of concrete. This new type of road is now the subject of extended experiments by the United States Government. It has met with such pronounced success in Wayne county, Michigan, as to give that locality national celebrity. The Association of American Portland Cement Manufacturers has published for free distribution a comprehensive book, entitled "Concrete Highways," which will interest road supervisors, contractors and taxpayers in every section of the country. The book, which is handsomely and profusely illustrated, contains nearly a hundred pages. It was prepared by expert road engineers, and goes into every detail of construction, concluding with a tabular digest of concrete pavements in all sections of the country. The various chapters include discussion of bituminous compound wearing surfaces, grouted pavements, reinforced concrete pavements and specifications for the one and two-course types. In fact, the book covers the entire subject in the most reliable and authentic way. Road supervisors especially will find it of inestimable value, and the taxpayer will be extremely interested in the economical results obtained by the introduction of these durable concrete highways.

Tunneling: A Practical Treatise.—By Charles Prelini, C.E., author of "Earth and Rock Excavation," "Dredges and Dredging," "Earth Slopes, Retaining Walls and Dams"; Professor of Civil Engineering, Manhattan College, New York. Sixth edition, revised and enlarged. New York: D. Van Nostrand Co. Cloth; [illegible] Price, [illegible]

This standard treatise on tunneling needs little comment, for it is now in the sixth edition, and is recognized as an authoritative exposition of the subject. During the few years that have elapsed since the publication of the first edition of this work, the art of tunneling through different soils, and especially under large bodies of water, has made considerable progress. During the last ten years no less than eight sub-aqueous tunnels, involving the construction of sixteen tubes, have been constructed for the service of the city of New York alone.

This edition has been revised, so that the entirely new methods which have been introduced by professional men are here presented in due prominence.

Space has also been given to important tunnels recently built. This material illustrates the various methods discussed in the text, and brings out more clearly the characteristics of the different methods of tunnel excavation. The volume now forms an admirable treatise on the subject, and will, no doubt, meet the present requirements of both engineers and students.

Design of Steel Mill Buildings.—By Milo S. Ketchum, C.E., Dean of the College of Engineering and Professor of Civil Engineering, University of Colorado. Published by McGraw-Hill Book Co., New York. Third edition; cloth; size, 6½ x 9 in.; 562 pages; 66 tables and 270 illustrations. Price, $4.00 net.

In this third edition Professor Ketchum has brought this treatise on the design of mill buildings and the calculation of stresses in frame structures to date.

In the preface to the first edition he states that the book is intended to provide a short course in the calculation of stresses in frame structures and to give a brief discussion of mill building construction. The original edition admirably filled the place allotted to it by the author. The book has received a well-merited appreciation since it was first published. In this edition the chapters on Stresses in Frame Structures and Stresses in Bridge Structures have been re-written and enlarged; the "Specifications for Steel Frame Buildings" have been revised and re-written and many changes have been made in the text. The additions to the book include two Problems in Graphic Statics, and Appendix III., "Structural Drawings, Estimates and Designs."

A Textbook of Physics.—Contributors: A. Wilmer Duff, E. Percival Lewis, Charles E. Mendenhall, Albert P. Carman, R. K. McClung and William Hallock. Edited by A. Wilmer Duff, D.Sc., Professor of Physics, Worcester Polytechnic Institute, Worcester, Mass. Third edition, revised. P. Blackiston's Son & Co., Philadelphia. Cloth; size, 5½ x 8½ in.; 686 pages; 595 text illustrations.

This textbook of Physics has now reached its third edition, the first edition being published in 1908. As noted, it is the combined work of seven experienced teachers of College Physics. For this edition, entirely new parts on Heat, and Electricity and Magnetism have been prepared, and extensive changes have been made in other parts. To facilitate reference a list of tables of constants has been given, and the indexes have been somewhat increased.

Machine Design.—By H. D. Hess, M.E., Professor of Machine Design, Sibley College, Cornell University. Published by J. Lippincott Co., Philadelphia. Cloth; size, 6 x 9½ in.; 368 pages; 18 plates; 318 figures. Price, $5.00 net.

The book deals specifically with machine design as applied to hoists, derricks and cranes. While the book is written with special reference to the student, it will be well received by the practising engineer, particularly those who are directly engaged in the design of this particular field.

A determination of the stresses in frames and machinery is developed by the use of elementary theoretical principles. While empirical formulas are used throughout the book where the conditions call for such use, the theoretic development is used where possible. Many examples are shown throughout the text, and these are practically all drawn from present-day practice.

The book is divided into twelve parts under the following headings: Introduction, Frames and Girders, Brakes and Clutches, Winches and Hoists, Pillar Cranes, Jib Cranes, Under-braced Jib Crane, Inverted Post Crane, Wall Crane, Overhead Electric Travelling Cranes, Hoisting Engine, Locomotive Cranes.

The Introduction includes a discussion of the properties of materials and fibres used in this class of machine design, and a few pages are given to an exposition of the elements of graphic statics, followed by a discussion of rolling and sliding friction crane blocks and block efficiencies for chain and wire rope. The other parts of the book are devoted to a presentation of the theory of columns and beams, methods of determining stresses in different frames, the various forms of brakes and clutches, and the remaining portion of the book takes up under the several headings the design of different types of cranes.

The treatise will be a most valuable one as a book of reference for the practising engineer and as a textbook for the student.

Engineering Index Annual, 1911. 530 pages; cloth; edited and published by The Engineering Magazine, 140-142 Nassau Street, New York. Price $2.00. With this volume (the tenth) a continuous index to the engineering and technical literature of the past twenty-seven years is available.

Utilization of Peat Fuel for the Production of Power. A report by B. F. Haanel, B.Sc., chief of fuel testing division, Mines Branch, Department of Mines; being a record of experiments conducted at the fuel station at Ottawa, 1910-11. Eugene Haanel, director, Mines Branch, Department of Mines, Ottawa.

◆

CATALOGUES RECEIVED.

Cranes, Etc. Herbert Morris, Limited, Empress Works, Canadian office 79 Peter Street, Toronto, forward very complete catalogue covering all the different types of lifting machinery made by them. Catalogue is bound in cloth, 472 pages, and is printed on a heavy enameled paper.

Stump-Pulling Machinery. A pamphlet forwarded by the Clyde Iron Works, Duluth, Minn., entitled "Cutting the Cost of Clearing Logged-off Land." This is a catalogue of stump-pulling and land-clearing machinery placed on the market by this company. The pamphlet is [illegible] attractively printed and illustrated.

Tool Holders, Drills, Etc. Armstrong Brothers' Tool Company, 330-357 North Francisco Avenue, Chicago, Ill., who are manufacturers of tool holders, ratchet drills, drop forged wrenches, etc., forward their catalogue [illegible] illustrating different types of their tools, together with a price list.

Suction Gas Plant. The British-Canadian Engineering and Supply Company, Limited, 122 Phœnix Block, Winnipeg, forward pamphlet entitled "No Power on Earth is Cheaper," being a description of the Ruston patent suction gas plant.

Tar Macadam Highways. The Barrett Manufacturing Company, of New York, Canadian agents, the Paterson Company, Limited, forward reprinted article entitled "Rhode Island's Tar Macadam Highways."

Hammer Drills. The McKiernan-Terry Drill Co., 115 Broadway, New York, forward illustrated catalogue of different types of their "Busy Bee" hammer drills.

Universal Packing. The H. W. Johns-Manville Company forward folder descriptive of their universal packing for use on rods, plungers and pistons.

Turn-Down Lamp. The Canadian General Electric Co., Limited, Toronto, forward folder illustrating a few of the many applications of the "Economical" turn-down lamp.

Modern Welded Pipe. The National Tube Company, of Pittsburg, Pa., have recently issued a book which gives a short history of the industry and considerable information relative to modern tubular products.

Sewer Flushing and Its Cost. A book on sewer flushing and a discussion of the cost of flushing at intervals; includes a discussion on the design of flush tanks. Issued by the Hydraulics Department, Merritt & Company, Camden, N.J.

Freight and Package Handling Machinery. Being Bulletin No. 74, illustrating the different types of freight and package handling machinery manufactured by the Jeffrey Manufacturing Co., Columbus, Ohio.

Motor Locomotives. A pamphlet issued by Ironside, Son & Dyckerhoff, 40 Mincing Lane, London, E.C., illustrating their "New Century" motor locomotives for surface haulages, also railway and passenger services.

Filters. Royles, Limited, Irlam, near Manchester, England, forward a complete set of their catalogues illustrating gravel filters, air heaters, calorifiers, steam traps, valves, etc.

Hydraulic Accumulators. Catalogue No. 84, just issued by the Watson-Stillman Co., and illustrating, tabulating and fully explaining the seven principal types of accumulators which they manufacture. A few pages are devoted also to accumulator accessories and to special hydraulic testing apparatus, reservoirs, etc. 56 pages; 6 in. by 9 in. A copy may be obtained by addressing the Watson-Stillman Co., 50 Church Street, New York.

The Pedestal Pile. The MacArthur Concrete Pile & Foundation Co., of 11 Pine Street, New York City, has recently published a new edition of their book, "The Pedestal Pile." The general layout of the book is the same as that of the first edition, but it contains a number of illustrations and descriptions of work recently completed and also other additions to the text. As the book contains much valuable data on the bearing power of soils, frictional resistance, etc., besides a complete description of the Pedestal Pile and how it is constructed, it should prove of interest to every engineer and architect.

Concrete Bridges. The Universal Portland Cement Company, Chicago, has published an attractive little booklet showing illustrations of a number of different highway bridges and giving a brief description of each. This booklet is entitled "Concrete Highway Bridges."

Appliances for Burning Fuel Oil. The Tate, Jones & Company, Inc., Pittsburg, has published a booklet entitled "Appliances for Burning Fuel Oil," which discusses oil as a fuel and illustrates and describes its various types of oil burners. Pumping systems for pumping, heating and regulating the oil flow to burners are also described.

COAST TO COAST.

Ottawa, Ont.—A sub-committee of the Dominion cabinet council has been appointed to consider the recommendation of the Royal Society of Canada for the establishment of a system of research stations throughout the country.

Vancouver, B.C.—By a vote of 37 to 24 the Vancouver Board of Trade rejected the report of the special committee which recommended that the Canadian Northern Railway be required to pay the city at least $2,000,000 for its terminals at False Creek.

London, Ont.—Scarcity of labor is proving a serious handicap to the extension work now being carried on by the Street Railway Company and they have notified the civic officials that they will be unable to complete their agreement by December 1st.

Saskatoon, Sask.—The Roberts filtration plant recently installed in Saskatoon is giving satisfactory results. The water is not only pure, but the bacterial contents are reduced to an infinitesimal point, with the result that the water is practically sterile.

Province of British Columbia.—The pay-roll of the Canadian Northern Railway for the month of September on account of construction work carried out in this province amounted to $1,454,000. The previous record for abnormal pay-rolls came to $1,100,000.

London, Ont.—Hon. Adam Beck is reported to have said that a friendly suit will be started against the Dominion Government in an endeavor to secure for the Hydro-Electric Commission control of all rivers in the province and of surplus water in the canals.

Athabasca Landing, Alta.—What is reported to be the heaviest flow of natural gas in the Peace River District has been located at this point. A pressure of 600 pounds to the square inch has been recorded so far and great precaution is taken to guard against accidental ignition.

Portage la Prairie, Man.—Mr. Hobbs, a civil engineer of Winnipeg, has arrived here to begin the work of locating a route for the proposed boat canal between here and Lake Manitoba. Some of the deep creeks extending into the prairie from the lake towards this place will be utilized in connection with the scheme.

Fort William, Ont.—The new million-dollar dock of the Canadian Pacific Railway has been placed in commission and the first freighter, laden with coal, will steam up the well-dredged McKellar River. A freighter laden with ten thousand tons of coal can be completely unloaded in ten hours at this new dock.

Outlook, Sask.—The bridge of the Canadian Pacific Railway across the Saskatchewan River at this point was sufficiently completed a day or two ago to allow trains on the main line between Edmonton and Minneapolis to pass. This bridge is a little over three thousand feet long and 156 feet high.

Sydney, C.B., N.S.—The "Duke of Connaught," the large drydock for Montreal, has been safely brought to this port. The trip across the Atlantic was made with difficulty, the towing cables parting five times. On one break the huge dock drifted thirty-five miles before it could be again secured to the tugs.

Quebec, Que.—Word has been received that Mr. Gauthier and Mr. Tremblay, of St. Jerome, Lake St. John, and Mr. Bedard, of Cape Bouge, three members of the expedition sent from Quebec in July by the government to survey the proposed James Bay route, were drowned in the Nottawa River during their journey.

Regina, Sask.—The commissioner of public health of Saskatchewan has strongly recommended the city of Regina to install a chlorinization plant for the purpose of treating the city water. This treatment of water by chloride of lime destroys typhoid bacteria without in any way injuriously affecting the water. While the source of Regina's water supply remains unprotected, it is the duty of the city to thus treat its water supply, thereby making it perfectly safe to drink. The water has been found by the city health officer to be polluted. He has recommended that it be boiled, but this is not always practicable. A chlorinization plant is very inexpensive to install and easy to operate.

Montreal, Que.—Judgment has been handed down by the Public Utilities Commission giving a general approval to the plans submitted by the Montreal Electrical Commission for the placing of the wires on St. Catherine Street, from Guy to Mance, underground. This approval is not, however, final, as certain modifications may be found necessary later, and the Electrical Commission can submit further recommendations and suggestions on which the Utilities Commission may act on its own responsibility without another inquiry. Work will be started next spring, and all the wires on this section of St. Catherine Street are expected to be safely stowed away in the conduit by the end of 1913. The conduits will be under the sidewalk at both sides of the street, ready access being given by large manholes at street intersections, and service manholes for making connections at various points. Sufficient space for all the wires will be provided, the conduits being 26 inches wide and 26 inches high. When the work is finished the appearance of Montreal's great shopping thoroughfare will be completely changed.

Regina, Sask.—Under an amendment to the Public Works Act of Saskatchewan, the Minister of Public Works was given power to make regulations governing townsites and subdivisions, and in accordance with this amendment regulations were brought into force on July 19, 1911. These regulations have undoubtedly accomplished a large amount of good in stopping undesirable subdivisions from going on the market and the selling of lots entirely unsuited for building purposes. The government sees that if a lot is sold a house can be built upon it, that there is proper access to it, and that the land is dry. A school site of at least one acre in every subdivision is insisted upon, and other provisions safeguarding the public interest are inserted in the regulations. The government, however, does not try to force any particular theory of town planning upon those laying out annexes. During the twelve months prior to February 29, 1912, there were 562 plans of subdivisions registered in the survey branch, as against 272 for the previous year. The fees to cover inspection and other services rendered by the department are about $4 per acre, and have resulted in the addition of about $60,000 to the revenue during the past year.

◆

MEETINGS.

UNIVERSITY OF MANITOBA.

Research work was the main theme in an address given by Dr. A. H. R. Buller at the opening session of the University of Manitoba. No university, he stated, could live to itself alone. It would indeed be shameful for the University of Manitoba to acquire all its knowledge from without and to contribute nothing. Besides this, there remained the consideration that the best teaching is always done in an atmosphere of research. To encourage research, professors should be free from lectures for at least half of every day. The question might be asked, what is the practical value of research work? Dr. Buller's reply was that the dollar was not the only form of wealth, and that intellectual wealth is the most valuable possession of any people.

A RECORD IN CONCRETE MIXING.

The rapidity with which concrete work can be done by an experienced gang and efficient machinery is exemplified by the following record recently made by workmen employed by the city of Toronto on Dundas Street, Toronto, using a Koehring No. 14 street mixer, made by the Canada Foundry Company, Limited. Seven hundred bags of cement, each weighing over 87 pounds, were put through the concrete mixer. It was also fed four cars of broken stone. Approximately 235 tons of concrete came out of the other end, and were laid in the roadway. This all happened in a working day of 540 minutes, so that about a ton of concrete was made, handled, and put in place every two and a third minutes. The 235 tons of concrete measured 175 cubic yards. In other words, it would have formed a pillar five feet square and [illegible] feet high—[illegible] feet higher than the Lumsden building.

Placing Concrete on Foundation for Civic Car Lines, Toronto.

◆

GENERAL REQUIREMENTS OF WOOD-PRESERVING OILS.

The value of any creosote as a preservative against decay is fundamentally dependent upon its ability to prevent the development of wood-destroying fungi. This prevention may be accomplished in either of the following ways:

1. By introducing a material sufficiently poisonous to wood-destroying fungi to prevent their development.

2. By introducing a material which will sufficiently exclude moisture so as to reduce the amount of either below that required by the fungi for their development.

In the past the creosotes which have been successful have generally possessed, at least to some extent, both of these properties; but the first is generally considered the more essential. In recent years, however, there has been some tendency to use materials not markedly antiseptic, but primarily intended to exclude moisture. As yet, however, it has not been completely demonstrated, nor generally accepted, that a product can be obtained to fulfil entirely the second requirement.

Aside from these considerations, it is of course essential that the creosote be of such a nature as to remain in the wood for the desired period of protection. In this connection its relative solubility in water and its volatility are important. However efficient it may be in poisoning the food supply or preventing the absorption of moisture, if it will not remain in the wood with a considerable degree of permanence, its ultimate value will be small. Where the treated wood is to be placed in wet situations or under water, as in the case of piling, a soluble preservative is inefficient; and a volatile preservative is especially unsuited for timbers exposed to the air in warm climates.

The relative ease with which a preservative can be injected is of much importance in wood-preserving operations; for this reason a product which is not sufficiently fluid at temperatures which can be conveniently used at commercial treating plants is undesirable. The presence of free carbon is known to decrease the penetrance of creosote and for this reason is objectionable.

◆

AMERICAN MINING CONGRESS.

As a result of the determined campaign for reduced rates to the fifteenth annual convention of the American Mining Congress, which will be held in Spokane, Wash., November 25-20, the transcontinental railroads have announced the following rates: From Missouri River points to Spokane and return, $[illegible]; from Chicago and return, $[illegible]. Tickets on sale November 9, 10, 11, 21, 22 and 23, with final return limit December 31. A rate of one and one-third fares, on the certificate plan, has been granted from local points.

DRAINAGE SCHEMES IN SASKATCHEWAN.

In a country such as the province of Saskatchewan, where the cultivated area is so small a percentage of the total acreage, it might at first sight seem superfluous for the people to spend much money and energy upon reclamation schemes, but the comparatively low cost per acre of such reclamation work, and the great fertility of what would otherwise be waste land, render such schemes very attractive.

Prior to the passage of the Drainage Act of 1909, the only drainage schemes in the province were built directly by the government out of the general revenue funds. The Act is now becoming more widely known amongst the agricultural community, and as a result there are several propositions under way at the present time. The following is a brief epitome of the working of the Act.

A petition to the government is prepared, which must be signed by resident owners representing at least one-half of the lands of resident owners. Upon receipt of the petition an engineer is appointed to prepare plans, estimates, and a report upon the feasibility of the scheme. When the report has been received and the plans examined, the whole must be submitted to the Lieutenant-Governor-in-Council for his approval. If approved, the next step is to advertise that it is the intention of the government to proceed with the work under the Drainage Act. The cost of the ditch is assessed against all the lands benefited. The signers of the petition have the privilege of withdrawing for any sufficient reason, such as, for instance, that the scheme is to cost more than they anticipated. After these withdrawals, if half the land of resident owners is not still represented, then no action takes place and the scheme falls through, otherwise the government proceeds to issue debentures, running for a term of from 20 to 35 years, to be retired by the assessments which are collected by the municipality.

There is no doubt that in course of time the Act will be more and more widely taken advantage of. The adoption of the Act not only gives a legal right to enter upon land and construct a drain, but renders possible very valuable reclamation work which would probably be beyond the means of a municipality or of any private company of settlers.

The drainage schemes mentioned here are all of them under way, and on some of them a large amount of construction work has already been done. There is the Egg Lake drain in township 20 range 15 west of the second meridian; a very large scheme near Invermay; one at Rama, and another near Shellbrook. The largest scheme of all is the reclamation of flooded lands southwest of Rouleau. It is estimated that this proposition will cost in the neighborhood of $40,000, but if carried out in its entirety will result in the reclamation of from thirty to forty thousand acres of land.

◆

MODULI OF ELASTICITY.

In a paper recently read before the Society of Engineers, Professor F. H. Hummel gives values of Young's modulus for a number of materials, as the result of experiments made on the flexure of thin strips:

Material.	E. Lb. per Sq. In.
Celluloid (1)	347,500
Celluloid (2)	547,000
Drawing-paper (in direction of rolling)	304,000
Drawing-paper (across direction of rolling)	581,500
Thick stiff paper	852,000
Box-wood	174,000
Whalebone	503,000
Copper	15,000,000
Brass	11,600,000
Aluminum-nickel alloy	10,000,000

PERSONAL.

MR. C. DURBAN, of the main drainage department, city of Toronto, has been appointed assistant city engineer of London.

MR. REGINALD A. DALY, formerly of Napanee, Ont., has been appointed head of the Geological Department of Harvard University, Cambridge, Mass., U.S.A.

LIEUT.-COL. GEORGE W. STEPHENS, chairman of the Montreal Harbor Board, in a letter to the Hon. G. D. Hazen, Minister of Marine and Fisheries, announces his resignation from the board.

MR. HARRY ANGUS, B.A.Sc., consulting engineer, Confederation Life Building, Toronto, has given up his practice and gone in with the Canadian Domestic Engineering Company, at their Toronto office.

MR. R. W. BROCK, director of the Canadian Geological Survey, visited Rossland, B.C., on his way east from Victoria, where he had been attending the British Columbia meeting of the Canadian Mining Institute.

MR. C. C. KRONK is in collaboration with Mr. Wynne-Roberts upon the question of development of electrical power for the province of Saskatchewan, and is making investigations into the possibility of economical transmission of such power.

MR. R. E. CHADWICK, who has been recently appointed as eastern manager in charge of the Montreal office of the Foundation Company, Limited, and who succeeded Mr. Alexander Allaire in that position, was born in Toronto. He is an honor graduate of the University of Toronto in mechanical engineering in the class of 1906. Mr. Chadwick was bridge engineer for the city of Toronto during 1909-10. He joined the Foundation Company, of New York in the first part of January, 1911, as superintendent on the Woolworth Building. In May, 1911, he joined the Foundation Company, Limited, of Montreal, Canada.

Mr. R. E. C. Chadwick.

DR. W. W. ANDREWS has been engaged in determining how the gumbo soil, found in some parts of the province of Saskatchewan, can be best treated to render it fit for road traffic. The work is being done under the Board of Highway Commissioners of the Province.

MR. M. J. BUTLER, general manager of the Dominion Steel and Coal Company, has resigned his position. Mr. Butler, as is well known, was deputy minister and chief engineer of the Department of Railways and Canals from 1905 to 1907 at Ottawa, when he was appointed to the general managership of the Dominion Steel Corporation. It is not known what he has in mind, although it is reported that he will become connected with another large undertaking.

MR. L. O. BEAM has resigned the position of inspector of public works of the province of Saskatchewan and has joined the staff of the R. J. Lecky Company. Mr. Beam was a bridge foreman under the old Territorial Government, whose outside staff he joined in 1889. He was afterwards in charge of ferry construction, and was appointed inspector of public works on the inauguration of the province in 1905. As a thoroughly practical man, with a thorough knowledge of all kinds of steel construction work, Mr. Beam's loss is a serious one. No successor has as yet been appointed.

MR. R. O. WYNNE-ROBERTS has been investigating since July 1st the lignite coal fields of Saskatchewan, in order to ascertain the feasibility of the generation of power and the distribution of it throughout the southern part of the province. Mr. Wynne-Roberts was city engineer of Cape Town during the Boer war, and was a consulting engineer in London, England, for some years. Since coming to Canada he made an inquiry into the water supply of the city of Regina.

COMING MEETINGS.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Monthly Meeting will be held in the Rooms of the Society, 413 Dorchester Street West, Montreal. [illegible] Chairman Henry Holgate.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Annual Convention to be held at Dallas, Texas, November 12th to 15th, 1912. Secretary, A. P. Folwell, 50 Union Square, New York.

NATIONAL ASSOCIATION OF CEMENT USERS.—December 12th to 18th. Annual Convention, Pittsburgh, Pa. President R. L. Humphrey, Harrison Building, Philadelphia, Pa.

AMERICAN CIVIC ASSOCIATION.—Annual Convention will be held at Baltimore, Md., November 19th to 22nd. Secretary, Richard B. Watrour, Union Trust Building, Washington, D.C.

AMERICAN RAILWAY ASSOCIATION.—Nov. 20th. Annual Meeting at Chicago, Ill. Secretary, W. F. Allen, 75 Church St., New York.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. Secretary, E. L. Power, 150 Nassau St., New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; [illegible]

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

[illegible] a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the [illegible]

[illegible] Building, Vancouver, B.C. Headquarters: McGill [illegible]

[illegible]

[illegible]

MUNICIPAL ASSOCIATIONS

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, [illegible] P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, [illegible] Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; [illegible] Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. [illegible] Hon. Secretary, Alcide Chaussé, No. 5 Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, [illegible] Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan [illegible] Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only, unless otherwise noted, at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
10-24	Construction of about 7¾ miles of Combined Sewers, New Westminster, B.C. ....(P. & S.)	10-10
10-24	Supply of 10,400 ft. reinforced concrete pipe, New Westminster, B.C. ....(P. & S.)	10-10
10-24	Supply of 1,660 ft. of 48" steel pipe, bends and specials, New Westminster, B.C. ...(P. & S.)	10-10

◆

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

TENDERS.

Albert, N.B.—Tenders for the construction of a wharf with approach and a bed for vessels, at Albert, Albert Co., N.B., will be received until November 18, 1912, at the office of R. C. Desrochers, secretary, Department of Public Works, Ottawa. Specifications, etc., at the office of that department, and at the offices of F. G. Goodspeed, Esq., district engineer, St. John, N.B., and on application to the postmasters at Albert, N.B., Moncton, N.B., Hillsboro, N.B., and Sussex, N.B.

Bassano, Alta.—The corporation of the town of Bassano, Alta., invite tenders, to be received until November 18th, 1912, for labor and materials required in connection with the waterworks system. Geo. B. R. Bond, secretary-treasurer. (See advt. and full particulars elsewhere in The Canadian Engineer).

Brandon, Man.—Tenders will be received at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa, until November 6th, 1912, for the construction of horse stable, Experimental Farm, Brandon. Plans, etc., at the office of Mr. H. F. Matthews, Architect, Winnipeg; the Superintendent, Brandon Experimental Farm, and at the office of the Secretary.

Cherhill, Alta.—Tenders for the erection of a school house in School District No. 2735, will be received until October 30th, by John Seedhouse, Secretary, Cherhill, Alta.

Dunnville, Ont.—Tenders for one steel elevated tank of 100,000 imperial gallons' capacity, will be received until November 11th, 1912, by B. L. Edgecombe, Chairman of Water commission. Alan Mair Jackson, superintendent. (See advt. in The Canadian Engineer).

Kamloops, B.C.—Tenders will be received up to noon of November 14, 1912, for the construction of intake dam and flume system for the proposed hydro-electric power plant on the Barriere River. Plans and specifications may be seen at the office of the City Clerk, Kamloops, and at the office of DuCane, Dutcher & Co., consulting engineers, Suite 911-914 Rogers Building, Vancouver, B.C. J. J. Carment, city clerk.

Kindersley, Sask.—The corporation of the town of Kindersley, Sask., invite tenders for all labor for constructing steel water supply main and distribution system, consisting of about 3 miles of 10-inch to 4-inch pipe, with specials, valves and hydrants, and to be completed July 1st, 1913. Tenders to be received until October 31st, 1912. D. MacTavish, Secretary-Treasurer.

Ottawa, Ont.—Tenders for the supply of sorting cases for post offices, and tenders for rural mail sorting cases for postal service, will be received until October 30th, 1912. Plans, etc., at the office of Mr. T. A. Hastings, Clerk of Works, Postal Station "F," Toronto, Ont., and at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa, Ont.

Ottawa, Ont.—Tenders for the re-erection and completion of a Lobnitz rock breaker, will be received until November 14, 1912, at the office of R. C. Desrochers, secretary, Department of Public Works, Ottawa. Plans, etc., at the office of the secretary, and at the offices of T. H. Schwitzer, Esq., mechanical superintendent, Birks Building, Ottawa, Ont.; and C. E. W. Dodwell, Esq., district engineer, Halifax, N.S.

Paris, Ont.—The time for the reception of tenders for additions and alterations to public building, Paris, is extended to Monday, November 4th, 1912. R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Toronto, Ont.—Tenders will be received until November 5th, 1912, addressed to the Chairman of the Board of Control, City Hall, for gradings, concrete walks, sewers, and supplying of 30-inch cast iron pipe, on a number of streets in the city of Toronto. Specifications may be seen at the office of the Commissioner of Works, Toronto. H. C. Hocken (Mayor), chairman, Board of Control, City Hall, Toronto.

Toronto, Ont.—Tenders for the installation of one or more fifteen million imperial gallon pumping engines and boilers at the main pumping station, will be received until noon of December 10th. Specifications, etc., may be obtained on application at the office of Mr. James Milne, mechanical and electrical engineer, Department of Works, City Hall, Toronto. H. C. Hocken (Mayor), chairman, Board of Control, City Hall, Toronto. (See advt. in Canadian Engineer.)

Winnipeg, Man.—Tenders for 17 library bookcases required in connection with the St. John's and Kelvin Technical High Schools will be received at the office of the Winnipeg School Board until November 7th, 1912. Full particulars may be had from J. B. Mitchell, Commissioner of Supplies.

Winnipeg, Man.—Tenders addressed to the Chairman, Board of Control, will be received until October 31st, for supply of labor and materials required in the excavation of earth for an 18,000,000-gallon reservoir. Plans, etc., at the office of the City Engineer, 223 James Avenue. M. Peterson, Secretary, Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders addressed to the chairman, Board of Control, will be received at the office of M. Peterson, secretary, Board of Control office, Winnipeg, until November 8th, 1912, for supply of twenty-five 36-inch gate valves for the domestic water works system. Specifications, etc., at the office of the City Engineer, 223 James Ave.

CONTRACTS AWARDED.

Beaverton, Ont.—Construction of breakwater, sheet piling and dredging: Contract given to D. Conroy, Esq., of Peterboro, Ont., at $41,874.

Fairhaven, Deer Island, N.B.—Construction of public wharf: C. A. Huntley, Esq., of Parrsboro, N.S., at $5,750.

Fort William, Ont.—Dredging: The Great Lakes Dredging Co., Ltd., of Port Arthur, at 25c. per cubic yard, place measurement.

Lanoraie, Brethier Co., P.Q.—Partial reconstruction and extension to wharf: Contract given to Arthur Taigneault, of Longueuil, P.Q., at $6,345.

Lethbridge. Alta.—The contract for the building of the Empress Theatre on Fifth Street, has been let to Messrs. Smith Bros. & Wilson. The building will cost $25,000.

Massett, B.C.—Contract for the construction of wharf here has been awarded to W. G. Gillett, of Vancouver, at $4,875.

Niagara Falls, Ont.—The contract for the installation of a new centrifugal pump has been awarded to the Canada Foundry Company, of Toronto, their contract price being $5,700. Tenders were also received from the following:—Messrs. Escher Wyss & Co., Montreal; John Inglis Co., Toronto; Buffalo Steam Pump Co., Buffalo; John McDougall Iron Works, Montreal; Drummond McCall Co.

Port Arthur, Ont.—The Canadian Stewart Co. are reported to have [illegible] the contract for [illegible] eight story building. Excavation has been begun.

Regina, Sask.—Messrs. Lyall-Mitchell Company were the successful tenderers to bid for the work of erecting a new warehouse for the H. G. Smith Company, Ltd. The cost of this work will be $[illegible]. The construction will be of [illegible] mill method.

Seaforth, N.S.—The Dominion Government has awarded a contract to the [illegible] Co. for the construction of a breakwater at this point to cost $[illegible].

◆

RAILWAYS STEAM AND ELECTRIC

Edmonton, Alta.—The directors of the Edmonton Interurban Company have commenced construction operations on an electric line from the city to St. Albert, a distance of [illegible] miles. This company, organized by Canadian and French capitalists and has a charter which empowers it to construct and operate about [illegible] miles of electric lines in the province of Alberta. Mr. [illegible], of Paris and Vancouver, is the representative for the French investors and [illegible], consulting engineer, is in charge of construction work.

Regina, Sask.—The Grand Trunk Pacific will build a [illegible] mile spur to connect Regina with the present line from [illegible], which runs southward to the international boundary and links up with the Great Northern.

LIGHT, HEAT AND POWER.

Brantford, Ont.—The ratepayers carried the hydro-electric by-law with a majority of 248. This calls for an expenditure of $115,000. T. H. Jones, city engineer.

Toronto, Ont.—Street lights will be erected on both sides of the Lake Shore Road from West of Keele Street to Sunnyside railway crossing.

Vancouver, B.C.—The following tenders have been received by the corporation council for the installation of lighting facilities on several streets.

Main Street—Standard Engineering Company, $7,490; Electrical Construction Company, $5,256; Mather, Yuill & Company, $5,307; M. P. Cotton Company, $7,899; Hudson Brothers, $7,333; Waugh, Misener and Bailey, $3,850.

Granville Street—Standard Engineering Company, $4,930; Electrical Construction Company, $3,650; Mather, Yuill & Company, $3,704; M. P. Cotton Company, $5,385; Hudson Brothers, $7,333; Waugh, Misener and Bailey, $3,850.

Carrall Street—Standard Engineering Company, $10,700; Electrical Construction Company, $7,527; Mather, Yuill & Company, $7,641; M. P. Cotton Company, $10,695; Hudson Brothers, $7,333; Waugh, Misener and Bailey, $3,850.

Hastings Street East—Standard Engineering Company, $6,850; Electrical Construction Company, $4,001; Mather, Yuill & Company, $4,216; M. P. Cotton Company, $6,180; Hudson Brothers, $4,359; Waugh, Misener and Bailey, $3,850.

Victoria, B.C.—The management of the British Columbia Electric Company have decided on a further expenditure of $1,500,000 to bring the capacity of the Jordan River plant up to 24,000 h.p. This is in addition to the increase that has just been commenced.

◆

GARBAGE, SEWAGE AND WATER.

Niagara Falls, Ont.—Notice of a by-law to build a trunk sewer along Muddy Run, has been given to the city council, Mr. J. C. Gardner, City Engineer.

Toronto, Ont.—The municipal controllers have had submitted to them the specifications of the new $350,000 pumping equipment to be installed in the main pumping station. Commissioner Harris will call tenders in a short time if the plans meet with the approval of this body.

Winnipeg, Man.—Col. Ruttan, city engineer has estimated the cost of a new reservoir to be erected on Logan Avenue West, to be $532,000. Tenders for the excavation work are to be called in a few days.

◆

BUILDINGS AND INDUSTRIAL WORKS.

Calgary, Alta.—A party of Vancouver capitalists are about to erect a factory in this city for the manufacture of paper from waste straw. This plant will cost about $75,000.

Fort William, Ont.—As soon as plans are passed the Canadian Northern Railway will erect a station in this city to cost about $20,000.

Fort William, Ont.—Alderman O'Donnell, of the municipal council, is advocating the erection of a civic rock crushing plant for use in the various paving works to be carried on by the city.

Guelph, Ont.—Dr. Howitt, medical health officer, has recommended the erection of a civic rendering plant to cost $1,500.

Guelph, Ont.—A report states that the management of the Page Hersey Company, will increase the capacity of their pipe mills by the addition of a $[illegible] plant, providing that satisfactory arrangement regarding a fixed assessment can be concluded with the civic officials.

Medicine Hat, Alta.—The directors of the Medicine Hat Rolling Mills, at a meeting held recently, decided to commence building operations at once. Messrs. A. J. Scott and B. Shragge, of Winnipeg, Manitoba, are interested in the project.

Montreal, Que.—A new $5,000,000 plant for the manufacture of steel barrels and commercial packages is to be

Tarvia

Preserves Roads
Prevents Dust—

Section of Government Parkway, Ottawa, Canada, treated with Tarvia B.

The Property Owners' Investigation.

IN the City of St. Thomas, Ont., the property owners on Gladstone Avenue contemplated petitioning the City Council to improve the roadways. They commissioned one of their number to visit various American cities, inspect pavements and make a report. Their investigator, Mr. E A. Horton, visited various cities in New York and New Jersey. In his report he made the following statements:

"I saw a 'Tarvia X' road in Rochester which extends from the city to the lake front, a distance of about six miles. It had been in use for eighteen months, and when I saw it, it was in excellent condition, with heavy traffic over it every day. I........inspected a piece of road in Newark........the surface when finished was smooth, and to my mind was one of the finest pieces of road it was my privilege to see. We then inspected another piece of 'Tarvia X' which had been done by the Road Commission two years ago........Constant heavy traffic passes over this road every day, and trucks have loads of from 6 to 8 tons. Steel-tired drays were used with most of their heavy traffic. This piece of road, as I saw it, did not show any wear whatever, and was apparently in as good condition as when it was put down.

"I did not confine my attention to Tarvia roads as I saw (here he mentioned five of the commonest types of road treatment) and every other kind of road that is known.

"I must say after making enquiries from people who were in no way interested, nor did they know I was seeking information, that everyone had a good word to say for the Tarvia road. I have no hesitation in recommending it for use on our street, and at the estimate cost that has been given us, after seeing the many pieces of road that I have seen, I think it is the cheapest road that can be built."

The foregoing is quoted from the St. Thomas, Ont., Journal on February 20th, 1912. Since that date Gladstone Avenue has been constructed with Tarvia X.

Anyone who will investigate the road problem with the same thoroughness will reach similar conclusions. Tarvia is made in three grades:

"Tarvia X" for use in constructing roads and pavements.

"Tarvia A" for hot surface applications.

"Tarvia B" (applied cold) for dust prevention and road preservation.

Booklet describing the latest developments in methods for building tarviated roadways and pavements will be sent free on request. Address our nearest office.

THE PATERSON MANUFACTURING COMPANY, LIMITED
MONTREAL TORONTO WINNIPEG VANCOUVER
THE CARRITTE-PATERSON MANUFACTURING CO., LIMITED
ST. JOHN, N.B. HALIFAX, N.S.

erected near Montreal, a group of influential Canadians, including Sir William Van Horne, Sir William Mackenzie, and Messrs. George F. Johnston, C. W. McLean, and J. Wesley Allison, having secured from the Steel Package Company of New York the patents to carry on the business in Canada. The new concern is to be known as "The Canadian Steel Package Company," and it is probable that Sir William Van Horne will be the first president.

Montreal, P.Q.—Mr. L. G. Read, consulting engineer and financier, is at the head of a recently formed syndicate that propose to erect a number of large buildings on the water front of this city and rent out various spaces to manufacturers for the carrying on of their business.

Ottawa, Ont.—The management of the Ottawa Electric Railway Company have received a permit for the erection of a $25,000 addition to the car barns on Coburg Street.

Ottawa, Ont.—The management of the Merchants Bank of Canada will erect a tall office building in this city. It will be 8 story in height and will be erected on the lot now occupied by the Seybold building.

Port Arthur, Ont.—W. H. Nelson has commenced the construction of a 2-story block at corner of Cumberland St. and Cameron St. Estimated cost $30,000. J. E. Jenkinson, contractor.

Port Arthur, Ont.—The Industrial department of the municipality state that a large plant for the manufacture of wire, nails, fencing, etc., will be established in this city. Messrs. Swimmerton and Bruitnel, Montreal, are acting for the interested parties in the preliminary stages of the proposition.

Preston, Ont.—The council will ask the ratepayers to vote on an industrial by-law in connection with the locating in this town of a large industrial manufacturing concern. The names of the interested parties are not made public.

Prince Albert, Sask.—Mr. H. C. Struchen, of Minneapolis, U.S.A., has completed all arrangements with the municipal council for the erection of a $250,000 pulp and paper mill.

St. Thomas, Ont.—The Industrial Committee have appointed a committee to make a thorough report on the standing of a Detroit shoe manufactory that desire to locate in this city. Ald. Saunders is a member of the committee.

Toronto, Ont.—The municipal board of control have received an offer to rent the property now occupied by the Bay Street fire hall. It is reported that a syndicate headed by ex-alderman Norman Heyd will erect a tall office building if the terms of the agreement meet with the approval of the [illegible]

Vancouver, B.C.—Mr. J. W. Weart, is forming a company [illegible] 15 story [illegible] building in this city, to be completed by April 1914. The cost of this work is placed at $700,000 and already the directors of the scheme are considering the calling of tenders and other building materials that will require time for delivery.

CURRENT NEWS.

Haileybury, Ont.—The plant of the Energite Explosive Company, at this point was destroyed by an explosion the force of which gave the entire town a severe shaking up.

Montreal, P.Q.—Chief Tremblay, of the Montreal Fire Brigade, has recommended that the civic officials purchase a fire boat for the protection of the rapidly growing harbor of this city.

Preston, Ont.—A report states that the management of the Preston Car and Coach Company, Preston, Ont., have made an offer to the Toronto city council to build the cars required for operation on the proposed civic car lines.

Regina, Sask.—It is reported that an early start will be made on a hotel for the Grand Trunk Pacific Railway costing $1,000,000.

St. Lambert, P.Q.—The following tenders have been received for the construction of an outfall sewer:—Superintendent of works, $75,070.76; C. J. Wills (Montreal and London, Eng.), $76,000; A. S. Dickison, $79,100; T. Guay, $80,332; J. Jackson, $85,000. Eight applications for specifications, etc., had been received. The original estimate for the work was $99,622.60, which included a 10 per cent. contingent. To each of the above contracts must be added $18,580.80 for pipes to be supplied by the town, and $195.95 for manhole covers. The award has not yet been made.

◆

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending October 14th, 1912:—

A Lancashire firm make inquiry for the names of Canadian firms able to supply short-end lumber in 500 and 1,000-ton lots, suitable for the box-making trade.

A Dundee firm manufacturing jute cloth, burlaps, etc., used for packing and covering purposes, desire to appoint agents at Berlin, (Ont.), Hamilton and Toronto.

A London correspondent is commissioned to arrange for the Canadian representation of a United Kingdom firm of machinery manufacturers, and would like to hear from reliable firms in the Dominion.

From the branch for city trade inquiries, 73 Basinghall Street, E.C.

A Scottish firm manufacturing household and toilet ammonias and liquid cleansers, wish to arrange with some resident Canadian firm who cover the whole of Canada to introduce their specialties.

A London firm manufacturing building specialties, and more particularly a novelty in flooring tiles, wishes to be placed in touch with Canadian resident firms who could handle these lines.

A London firm are desirous of getting into touch with firms handling Canadian chrome ores (50 per cent. Cr_2O_3).

DEPT. OF RAILWAYS AND CANALS, WELLAND

Superintending Engineer's Office,
Messrs. Wettlaufer Bros., St. Catharines, Feb. 7th, 1912.
No. 178 Spadina Ave., Toronto.

Dear Sirs :—Replying to yours of the 6th, I beg to say that the two Mixers received from you last summer proved to be very handy, useful machines. They turned out excellent concrete and we had no trouble with them at all.

Yours truly, J. L. WELLER, Superintending Engineer.

CANADIAN NORTHERN RAILWAY

Belleville, Ont., Feb. 14th, 1912.
Wettlaufer Bros.,
178 Spadina Ave., Toronto, Ont.

Dear Sirs :—I think it is my duty to inform you that I am entirely satisfied with the two Concrete Mixers purchased from you last season. I have tested them in every way possible, and in every case I have found them capable of doing first-class work. Yours sincerely, J. O. GIROUX.

We have manufactured concrete mixers and concrete machinery of all kinds for many years; also previously had taken contracts for concrete work of all kinds, and have had the actual experience of just what a concrete mixer should do. Wettlaufer Mixers are perfect to-day through the help of the hundreds of contractors who purchased Wettlaufer Mixers in past years. We have gone personally to them and watched these machines working on all classes of work, asked the contractors their opinions, and so have evolved the present perfect mixer.

Compare the thoroughness, simplicity and durability of our mixer with other makes. The Wettlaufer Mixer is of the heart-shaped drum type; this means quick and positive mixing and the saving of power.

CLASSIFICATION OF CLAYS.

Considering the different ways in which clays have been formed, it is possible to formulate the following classification, based primarily on their origin, and also bringing out, somewhat, their commercial characters. This classification is abstracted from a preliminary report on the clay and shale deposits of the western provinces by Heinrich Ries and Joseph Keefe, of the Geological Survey Branch, Canada, Department of Mines. Examples are given where known in the western provinces.

A. Residual Clays. (By decomposition of rocks in place).

I. Kaolins or china-clays. (White burning, and derived from igneous or metamorphic rocks low in iron oxide).

(a) Vein-like deposits derived from pegmatite veins, or dykes of igneous rock, such as rhyolite.

(b) Blanket deposits, derived from extensive areas of igneous rock. (Kyuquot, Vancouver Island).

(c) Pockets in limestone, as the indianaite of Indiana, U.S.A.

II. Red-burning residuals, derived from different kinds of rocks. These may be formed by the decomposition of such rocks as granite, by a process of solution as in limestone, or by simple disintegration as in many shales.

B. Colluvial Clays, representing deposits formed by wash from the foregoing, and of either refractory or non-refractory character. (Field, B.C.).

C. Transported clays.

I. Deposited in water.

(a) Marine clays or shales. Deposits of ten of great extent. (Pierre shales)

White burning clays. Ball clays and plastic kaolins.

Fireclays or shales. Buff burning. (Dirt hills, Sask., and Clayburn, B.C.).

Impure clays or shales (Calcareous, Niobrara shales, Non-calcareous, Coleridge, Sask., shale).

(b) Lacustrine clays (deposited in lakes or swamps).

Fireclays and some shales.

Impure clays or shales, red-burning. (Edmonton shales).

Calcareous clays, usually of surface character (Cochrane, Alta., clay).

(c) Flood-plain clays. Usually impure and sandy. (Edmonton, Alta.).

(d) Estuarine clays (deposited in estuaries). Mostly impure and finely laminated. (New Westminster, B.C.).

[illegible]

Boulder clay. (Estevan, Sask.)

◆

POLES USED IN CANADA, 1911.

[illegible] over 21 per cent. of the total number were treated by the creosote or other methods. This is an increase of some forty-five per cent. over the number treated in 1909. At present the United States have a large number of timber-treating plants, while Canadian pole-users are only now beginning to treat their poles. It is to be hoped that this great inequality will soon be done away with and that pole-users in Canada may take up this cheap and rational method of securing greater service from the poles used and thus lessening the drain on the forest.

◆

CONDITIONS IN VANCOUVER.

Figures for the past month showing the activity along various lines in Vancouver may not appear so large in comparison with those of the same month of a year ago. It must be remembered that for many months this city's statistics were higher than those of all cities in Canada, and of all except the very largest cities in the United States. This could hardly be maintained, and if figures now show a falling off in percentage it does not indicate that a slump has occurred. Conditions on the coast have been somewhat peculiar during the past summer. Work has been active in every line of industry, perhaps more so that for some years past, yet actual money has been scarce. In past seasons there was often some disturbing influence. Perhaps it was a difference between employers and employees, with a cessation of labor as a result, or it might have been a slackness in the demand for a commodity that British Columbia produces.

This year it has been all the other way. The price of copper has been better than for a long time past, and metalliferous mines in the southeastern part of the province, and on the coast, have been in active operation. In the lumber industry, there has been a strong demand locally and foreign. Railway construction has been proceeding on a large scale all over the lower and upper mainland and on Vancouver Island, and a very large amount of money must have been put in circulation owing to this work, both in wages and supplies. Yet money has been scarce for four months past, and big firms which usually are not affected by these temporary stringencies, have had to resort to paper. The cause of this is said to be the numerous real estate subdivisions, which have taken a large portion of the ready money and diverted it into a few hands. Rather than forfeit payments, buyers have let merchants' accounts stand, and this has meant that other dealers have missed the circulation of the cash. The good conditions of the past few months are continuing and business is opening up better, and with a good crop on the prairie the outlook is exceedingly satisfactory.

Negotiations between Vancouver city council and the Canadian Northern are proceeding, and have reached the stage where the agreement as completed in committee will be submitted to the city council. The city has been successful in securing many of the concessions asked for, and the railway company's representatives, while not disguising the [illegible] Creek, have made very reasonable allowances. Already the ratepayers in one section of the city, through an association meeting, have approved of the plan as drafted, which indicates the satisfactory [illegible]

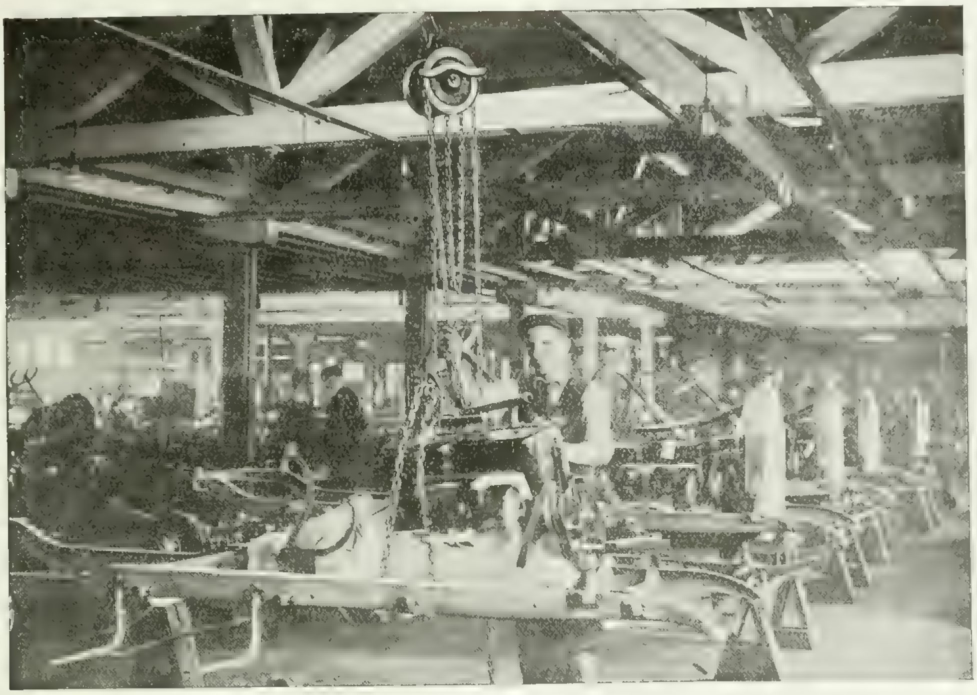
[illegible] Montreal.

THE TRIPLEX BLOCK



Placing engine in chassis with a half-ton Triplex Block.

A 100-page Book on Hoists

Practical engineers are all agreed that radical cuts in cost can be brought about by solving hoisting problems. Such problems are not solved satisfactorily by heavy cranes which do not give continuous service. A load that is waiting to be moved is costing money just as much as a load which is taking a gang of workmen to move.

A hoisting problem is not solved until each workman can readily lift and transport any load, single handed, that comes to him.

The new Book of Hoists shows examples of hand and power hoisting and overhead apparatus for conveying in model plants, here and abroad. The information is the most complete we have ever published. We will be glad to send a copy free on request.

Triplex Blocks; **16 Sizes:** One-quarter of a ton to forty tons. **300 Active Stocks** all over the United States. **Every Block Tested to 50 Overload.**

[illegible]—October 14—Authorizing Esquimalt & Nanaimo Ry. Co., to construct spur for D. McKenzie, in city of Victoria, B.C.

[illegible]—October [illegible]—Authorizing Municipality of Tp. Barton and the Hamilton City and Suburban Homes, Ltd., to construct Rosedale Ave., at grade, across [illegible] line of T.H. & B. Ry.

[illegible]—October [illegible]—Authorizing C.P.R. to construct bridges Nos. 24.2 and 24.1 on its Toronto Subdivision, over Otonabee River.

17776—October 16—Authorizing C.L.O. & W. (C.P.R.) to construct bridge at mileage 130.21 across road allowance between Lots 18 and 19, Con. [illegible], Tp. [illegible] Hope.

17777—October 16—Authorizing Can. Nor. Alta. Ry. to construct across G.T.P. Ry. [illegible] N.E. ¼ Sec. [illegible], Tp. [illegible], R. 1, W. 5 M., Alta., by means of structure carrying its railway under G.T.P.

17778—October 17—Authorizing C.N.R. to construct Prince Albert-Battleford Line across [illegible] highways in Prov. Saskatchewan.

17779—October 17—Authorizing C.N.Q. Ry. to construct across public road in village of St. Eustache, between Lot 51, Parish St. Eustache, and Lot [illegible], village of St. Eustache, Co. Two Mountains.

17780—October 17—Authorizing G.T.P. Ry. to carry traffic on its Moose Jaw Branch between Regina and Moose Jaw, in Prov. of Saskatchewan, [illegible]

17781—October 16—Postponing effective date of Order No. 17552, dated September 21st, 1912, directing G.T.R. to restore proportion, namely 88 [illegible] Bradford, [illegible]

17782—October 17—Authorizing C.N.O.R. to construct across public [illegible]

[illegible] C.N.O.R. [illegible] St. Lawrence Boulevard and St. Denis Boulevard, in city of Montreal, by means [illegible]

[illegible] Railway to take [illegible] Ry.

[illegible]

[illegible] press Co.'s delivery limits in city of Halifax, N.S., be enclosed by water front as north-westerly boundary from east end of Miller St., from south [illegible]

[illegible]

[illegible]

[illegible]

[illegible]

[illegible]

[illegible]

[illegible]

[illegible]

[illegible]

17796—October 18—Approving C.L.O. & W. (C.P.R.) plan of undercrossing at mileage 1[illegible].48, between Cons. 3 and 4, Tp. Pickering.

17797—October 17—Approving V.V. & E. Ry. & Nav. Co. plan showing additional land required for the accommodation of its slopes and bridges over Sumas River, British Columbia.

17798—October 19—Approving C.N.O.R. location through unsurveyed territory in Dist. Thunder Bay, mileage 398 to mileage 413, from Sudbury Junction.

17799—October 19—Approving G.T.P. station site and station at Tete Jaune, Dist. Fort George, B.C.

17800—October 17—Approving James Bay and Eastern Ry., location of station grounds at Pointe Bleue, Tp. Ouiatchouan, Que., mileage 5.

17801—October 18—Granting leave to N. St. C. & T. Ry. to cross G.T. Ry. on Welland Ave., in city of St. Catharines, Ont.

17802—October 12—Authorizing C.N.R. to construct bridge across the Atikokan River at mileage [illegible].

17803—October 18—Approving revised location C.N.O.R., through Tp. Nelson, up east side of Tp. Flamboro, mileage 31.54 to mileage 37.50 from Toronto.

17804—October 19—Authorizing C.P.R. to construct spur for Robertson Gravel Co., Ltd., Lot 2, R. 5, and Lot 1, R. 6, Tp. Waxford, Co. Terrebonne, Que.

17805—October 16—Authorizing C.P.R. to move station on Lot 2, Con. 5, to Lot 2, Con. 3, Tp. West Zorra, at Ingersoll Jct.

17806—October 18—Directing G.T.R. to provide and construct farm crossing for Julius E. Rosger, Lot 7, Con. 10, Tp. Ellice, Ont.

17807—October 11—Authorizing C.N.R. to construct bridge across Kashabowie River on main line east, mileage 80.7.

17808—October 19—Requiring C.P.R. to fence its right-of-way at Duck Cove, N.B., on south side of D. R. Jack's west line to a point 100 ft. east of Mrs. De Soyres' Gate

17809—October 19—Authorizing C.P.R. to construct extension to side already constructed for Guelph Stove Works, Guelph, Ont.

17810—October 21—Approving location C.N.R. through town of Estevan, Sask., mileage 8.02 to mileage 8.98.

17811—October 21—Authorizing C.N.O.R. to construct across Concession Road between Cons. [illegible] and 11, Tp. Chisholm, station 47.53.

17812—October 22—Authorizing C.P.R. to operate trains, without their first being brought to a stop, over westbound second track where same crosses C.N.R., Bird's Hill Branch in S. ½ Sec. 16, Tp. 11, R. 4, E. P. M., mileage 11[illegible].18 near Woods, Manitoba.

17813—October 19—Approving Joint Passenger Tariff of Tolls, Supplement No. [illegible] to C.R.C. No. [illegible], of the White Pass & Yukon Route.

17814—October 21—Directing C.N.O.R. to construct farm crossing for George Boyce, Lot [illegible], Con. [illegible], Tp. Nepean, Co. Carleton, Ontario, at Station 4[illegible].

17815—October [illegible]—Appointing Commissioner McLean to examine, under oath, any witness resident or at present in Canada, who may be produced to give evidence material to complaint of Blind River Board of Trade and London Rolling Mill Co., Ltd., alleging that G.T.R. and C.P.R. unjustly discriminate against town of Blind River on shipments of bar iron.

17816—October [illegible]—Authorizing C.N.O.R. to construct across six (6) highways in Tp. Chisholm, Dist. Nipissing.

17817—October 22—Authorizing (temporarily) G.T.P. Branch Lines Co. to carry traffic over Oban-Battleford Branch, mileage 0 to mileage 48.5.

17818—October [illegible]—Authorizing C.P.R. to take, for the construction of a team yard, certain lands in the Civic Delorimier Ward of city of Montreal, Que.

17819—October 22—Authorizing C.P.R. to cross, at grade, Pelham Ave., at West Toronto, Ontario.

17820—October 22—Approving location C.N.R., through Tps. 35-38, R. [illegible], W. [illegible] M., Sask., mileage [illegible] to mileage 135.5.

17821—October 21—Approving location Vancouver, Victoria and Eastern Ry. & Navigation Company's [illegible] track between mile post [illegible]

[illegible]—October [illegible]—Authorizing C.P.R. to take, for purposes of constructing a Team Delivery Yard, certain lands fronting on Mance St., and Esplanade Ave., [illegible] Ward in city of Montreal, Que.

17823—October 22—Authorizing C.L.O. & W. (C.P.R.) to construct [illegible] to mileage 16[illegible].

17824—October 21—Approving location C.N.O.R. through Con. Hochelaga, [illegible]

[illegible] C.P.R. [illegible] spur for Paquette [illegible] Laval, Quebec.

[illegible] tariffs of C.P.R., G.T.R., Can. Nor. Que., & Temiscouata Rys. increasing rate on shipments of pulpwood.

[illegible] branch line from [illegible] Mine and rescind [illegible] May [illegible]

[illegible] G.T.R. [illegible] siding in the [illegible]

[illegible] siding for the [illegible]

[illegible] to construct [illegible] Tp. [illegible], R. 1, [illegible]

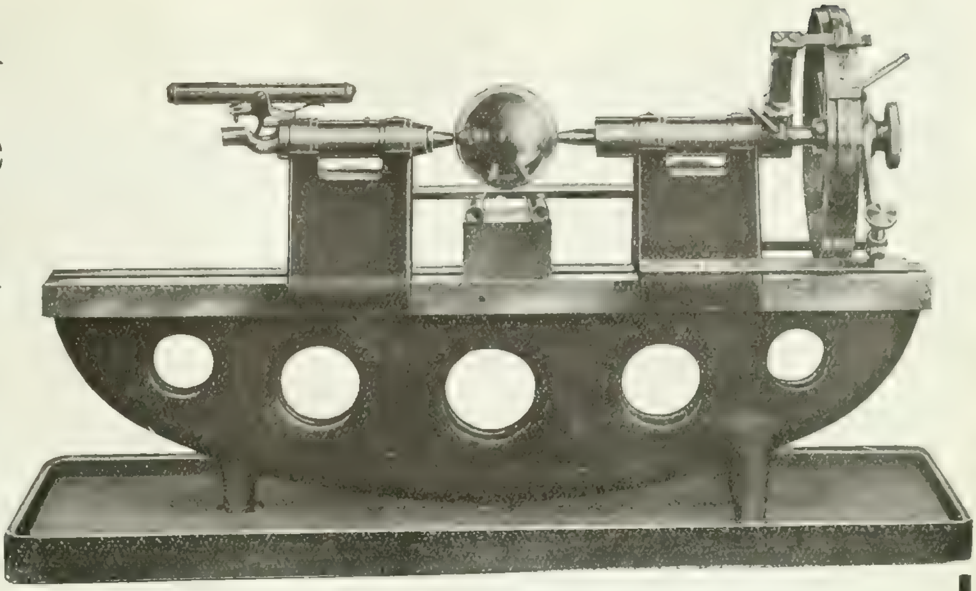
[illegible] freight traffic on [illegible]

[illegible] traffic its new second [illegible] at South Switch

[illegible] spur for the Can[illegible] Winnipeg, Man.

[illegible] C.N.O.R. station grounds at [illegible] Tp. [illegible], Ontario.

[illegible] Authorizing C.N.O.R. to construct across public road between Cons. A and B, Tp. Westmeath, Co. Renfrew, Ont.



Guaranteed Accurate to Within $\frac{1}{10,000}$ of an Inch.

NEWALL MEASURING MACHINE

HOFFMANN STEEL BALLS

Hoffmann Steel Balls are all perfect spheres, and the utmost care is taken to make them, as nearly as is commercially practicable, correct to standard size. For this purpose all Hoffmann Standards have been verified by the National Physical Laboratory at Bushey, Eng., and all gauges used are tested against these standards by means of a Newall Measuring Machine.

Any Hoffmann Steel Balls which vary one ten-thousandth of an inch from standard size may be rejected, and will be replaced free of charge.
All sizes in stock, from 1/16" to 4".

Centrifugal Pumps

For Contractors,
Pulp Mills, &c.

Our pumps, you will notice, are split horizontally instead of vertically. This makes them much easier to take apart when necessary, as you have only to take the bolts out of the top half of case and lift it off.

Their construction is simple and strong, and you'll find them good pumps.

MAY WE QUOTE?

William Hamilton Company, Limited
PETERBOROUGH - ONTARIO

TENDERS CALLED FOR

TOWN OF BASSANO, ALBERTA.

WATERWORKS.

The corporation of the town of Bassano, Alberta, invite tenders for the following:—

CONTRACT "T"—

All labor and materials for constructing a concrete pump shaft, 130 feet deep, and laying 18-in. steel intake pipe in tunnel from shaft to Bow River, 225 feet in length, and constructing intake crib in river.

CONTRACT "H"—

All labor and materials for constructing frame power-house at Bow River.

CONTRACT "F"—

All labor and materials for constructing frame frost casing for standpoint, 25 feet diameter x 112 feet high.

CONTRACT "P"

Supply and erection of a deep well pumping engine, or alternatively, of a centrifugal pump and steam turbin.

CONTRACT "R"—

Supply and erection of two return tubular steam boilers and stack.

CONTRACT "S"—

Supply and erection of a steel standpipe, 20 feet diameter x 100 feet high.

Plans and specifications for Contracts "T," "H," and "F" may be obtained from the John Galt Engineering Company, Limited, Winnipeg and Calgary, on deposit of cheque for $10.00, which will be returned to bona fide tenderers.

Specifications for Contracts "P," "R," and "S" will be sent on application to the Engineers.

Tenders, which must be accompanied by an accepted cheque for five per cent. of the amount of the tenders should be sent to the undersigned not later than 20 o'clock, on Monday, [illegible]

The corporation does not bind themselves to accept the lowest or any tender.

GEO. B. R. BOND,

Bassano, Alberta, [illegible]

Secretary-Treasurer

WATER COMMISSION,

TOWN OF DUNVILLE, ONT.

Sealed tenders addressed to B. L. Edgecombe, Chairman [illegible]

[illegible]

[illegible]

[illegible]

TOWN OF YORKTON, SASK.

TENDERS FOR AUTOMOBILE FIRE TRUCK.

[illegible]

[illegible]

Secretary-Treasurer

[illegible]

TENDERS FOR INSTALLATION OF ENGINES AND BOILERS.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, Canada, up to noon on

TUESDAY, DECEMBER 10th, 1912,

for the installation of one or more Fifteen Million Imperial Gallon Pumping Engines and Boilers at the Main Pumping Station.

Specification and tender form may be obtained upon application at the office of Mr. James Milne, Mechanical and Electrical Engineer, Department of Works, City Hall, Toronto.

Envelopes containing tenders must be plainly marked on the outside as to contents.

The usual conditions relating to tendering as prescribed by City By-law must be strictly complied with or the tenders may be declared informal.

Tenderers shall submit with their tenders the names of two personal sureties approved by the City Treasurer, or in lieu thereof, the bond of a guarantee company approved as aforesaid.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

City Hall, Toronto,
October 22nd, 1912.

QUEBEC HARBOUR COMMISSION

NOTICE

Sealed Tenders addressed to the undersigned and endorsed "Tender for Grain Elevator," will be received at the Quebec Harbour Commissioners' office up to 12 o'clock noon of October 21st, 1912, for the construction and delivery in complete order of a 1,000,000 bushel capacity Grain Elevator, with Marine Tower and shipping apparatus, to be situated on the Princess Louise Embankment, Quebec. Each Tender is to be accompanied by plans and specifications, exhibiting and describing the Elevator for the construction of which the Tenderer has submitted prices. Particulars of the requirements for the Elevator, etc., may be obtained by applying to the Harbour Engineer's office, Quebec.

Each Tender must be accompanied by an accepted bank cheque for $25,000 made payable to the order of the Chairman of the Harbour Commission. This sum will be forfeited should the tenderer refuse or neglect to enter into a contract for the construction of the Elevator, etc., if called upon to do so, and will be retained during the progress of the work as partial security for its due fulfilment; the unsuccessful Tenderers will have their cheques returned. The Commissioners do not bind themselves to accept the lowest or any tender.

RAOUL RENAULT,
Secretary-Treasurer,

EXTENSION OF TIME

The Quebec Harbor Commissioners have extended the time for the reception of the tenders for a grain elevator [illegible] until [illegible] and the time of delivery until August [illegible], 1914.

RAOUL RENAULT
Secretary-Treasurer

For further Tenders see page 76.

The Canadian Engineer

An Engineering Weekly

THE APPLICATION OF DIESEL ENGINES TO LAND AND MARINE WORK.

By D. M. BRIGHT.

Introductory.—Within the last decade no prime mover has provoked so much comment as the Diesel engine, and as within the last two years, almost daily reference has been made in regard to its development, it may be of interest to make some particular reference to its early history.

The earliest known internal combustion engine was invented and made by a French Abbé in the year 1682. This engine utilized the energy produced by the explosion of an inflammable powder, but difficulty was experienced in controlling the power. About two hundred years later Rudolf Diesel, a German scientist, after many years of study and experiments on different types of heat engines, formed the opinion that very little improvement in their heat efficiency could result until the principles of working were modified.

Herr Diesel, in order to demonstrate his theories, decided to construct a new type of heat engine to utilize the maximum amount of heat from the fuel used.

In this engine only pure air is drawn into the cylinder and compressed, then the oil fuel is injected into this compressed air in the form of a fine spray and burns gradually as long as the injection is maintained. During the whole cycle the pressure in the cylinder does not rise above the compression pressure, unlike the ordinary gas engine where the combustible charge is drawn into the cylinder, is ignited and burned instantaneously or exploded.

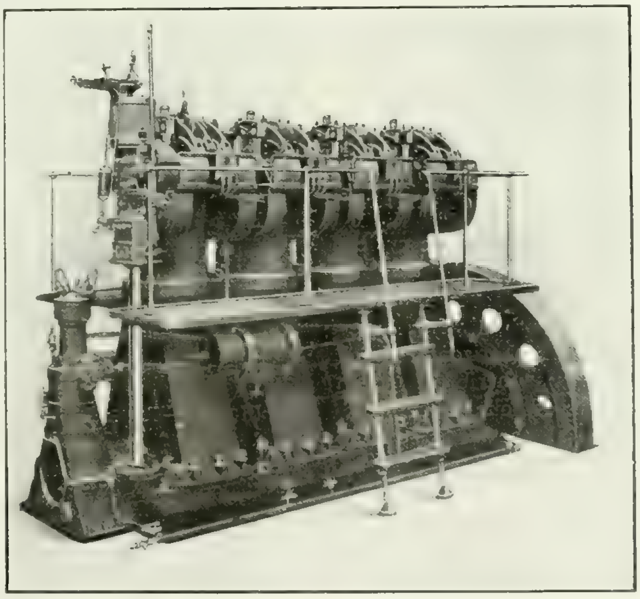

Fig. 1.—Four-Cylinder 200-h.p. Diesel Oil Engine.

In 1897, after four years of difficult experimental work, Dr. Diesel completed the construction of the first commercially successful motor in the Augsburg Works, and it was announced by the numerous engineering and scientific committees and deputations from various coutries, who tested the machine, that a higher heat efficiency was attained by it than by any other known heat engine. As a result of subsequent experience in practice, and the gradual improvement in the manufacture, still better results have been obtained and at the present time the thermal efficiency the motor attains is up to about 48 per cent., and the effective efficiency in some cases up to 35 per cent.

The results of this first motor were considered so satisfactory that a large number of engineering firms obtained licenses to build. At the beginning of 1901 twenty-five firms on the Continent, one in the United States, and one in Great Britain were costructing Diesel engines.

General Description.—The engines work on the four- and two-stroke cycle and run according to requirements at low or high speed, and are made in vertical or horizontal types.

Four- (Stroke) Cycle Engines.—(1) In the first downward stroke of the piston air is sucked into the engine cylinder direct from the atmosphere through the main air inlet valve on the top of the cylinder. At the end of this stroke the cylinder is full of pure air at practically atmospheric pressure, ready for the compression stroke.

(2) In the next upward stroke the air is compressed to the required pressure, usually about 500 lbs. per sq. inch, thereby having a temperature of about 1,000 deg. Fahr., all the valves, of course, being closed during this action. As the compression is very approximately adiabatic nearly all the work in it is returned.

(3) During the early portion of the third and working stroke the fuel oil is injected into the cylinder above the piston by a blast of air at a higher pressure than that in the cylinder (about 800 lbs. per sq. in.) through a special form of needle spray valve. Combustion takes place during this period as the temperature of the compressed air in the cylinder is above the burning point of the oil fuel. After cut-off, when the fuel inlet valve closes, combustion continues for a short period, expansion then occurs and work is done on the piston for the rest of the stroke. Just before the piston reaches the end of its stroke the exhaust valve begins to open.

(4) In the final stroke the exhaust valve remains open and the burnt gases are expelled from the cylinder into the exhaust pipe, leaving the cylinder ready to receive a further charge of gas on the next down stroke of the piston, when the cycle of operations begin once more. Fig. 2 shows an indicator card of an actual Diesel engine of this type.

Two- (Stroke) Cycle Engine.—(1) Consider the piston at the end of its stroke in the bottom position. The cylinder is then full of air at nearly atmospheric pressure, and this is compressed during the first or upward stroke of the cycle to the usual top compression pressure of 500 lbs. per sq. in., as in the second stroke of the four-stroke cycle.

(2) During the second stroke, combustion, expansion, expulsion of the burnt gases to the exhaust and the filling of the cylinder with fresh air are the operations which have to be effected. Fuel is sprayed into the cylinder during the early portion of the stroke, through the inlet valve, by compressed air as before. This valve then closes and expansion occurs while the piston passes through about 78% of its stroke, at which point the exhaust valve opens and the products of combustion begin to pass out. Air under pressure of about 4 to 8 lbs. per sq. inch then enters the cylinder through a separate valve or port in the cylinder, being supplied from a so-called scavenge pump, which is quite separate from the air compressor for the provision of fuel injection and starting air supply.

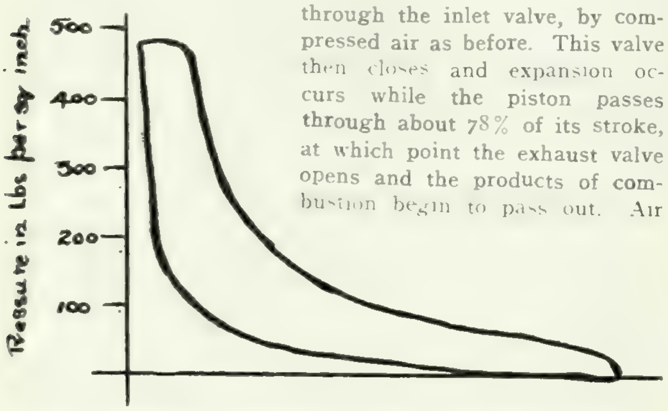

Fig. 2.—Indicator Daigram of Four-Cycle Diesel Engine.

All the exhaust gases are thus forced through the exhaust ports and at the end of the stroke the cylinder is left full of pure air with all the valves closed ready for the first stroke of the next cycle.

The indicator diagram for this cycle, as seen in Fig. 3, does not differ materially from that of the four-stroke cycle, as seen in Fig. 2, the most notable difference being the rapid fall off of pressure to F along E F; also during the process of exhaust the cylinder is filled with air from the scavenge pump. There is no longer a horizontal line representing the entrance of the air at atmospheric pressure, as in the four (stroke) cycle diagrams, since all the air is admitted at a pressure above atmospheric.

Figs. 1 and 4 are illustrations of Diesel engines used for electrical installations and pumping.

The main advantages of the Diesel engine are: (1) Its ex[illegible]

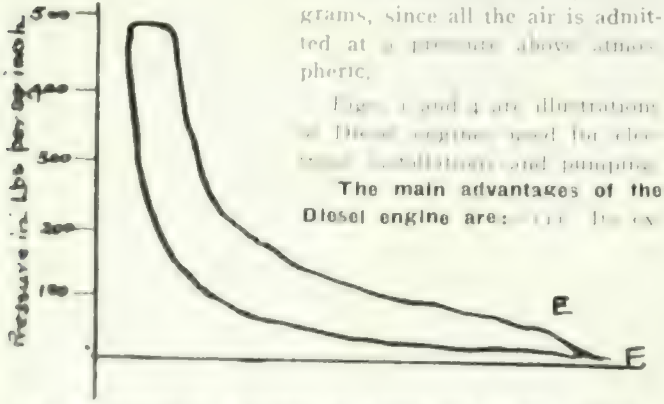

Fig. 3.—Indicator Diagram of Two-Cycle Diesel Engine.

[illegible]

(2) [illegible] large quantities all over the world.

(3) [illegible]

a not infrequent cause of breakdown in other forms of internal combustion engines.

(4) No carburetters, vaporizers or troublesome ignition devices are requied on the Diesel.

(5) The engine can be started up from cold and put on load in one minute. and is ready for any load up to its full capacity at any moment.

(6) Lastly, one of its most important features is its great reliability, even when running for long periods with variable conditions of load.

Application of Diesel Engines to Marine Work.—A marine engine must, before everything, be absolutely reliable, and with the present perfection of the steam engine, as a result of close on a century's practical experience, it is easy from this to see that the Diesel engine had to stand a long, severe trial during its progress up to the present before it could be seriously considered as a motor for marine work. After some eighteen years, during which the engine has proved its excellence for stationary work, with a reliability equal to the best steam engine and excelling all others, it may be said to have proved its worth beyond question. Of course, marine practice is in many ways different to stationary working. Marine engineers are naturally a little apt to exaggerate this point, still, there is no doubt that the conditions of service at sea are in general much more severe than on land. That over 400 vessels at present equipped with Diesel engines, many of these running for years, and the many that are being built is proof that there will be many such vessels in the future.

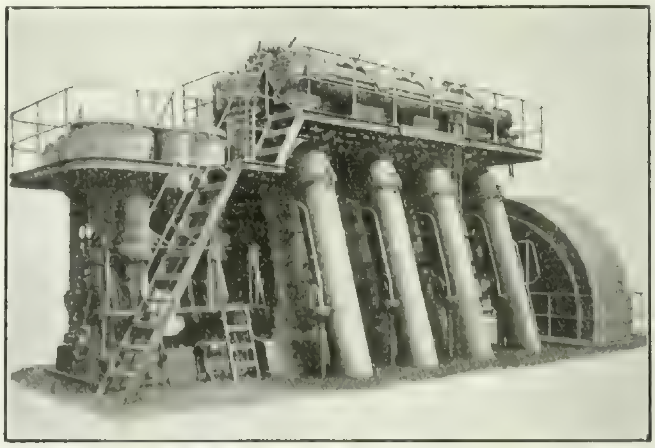

Fig. 4.—Four-Cylinder Two-Cycle 2,400 b.h.p. Engine.

Advantages of the Diesel for marine work are:—(1) Reduction in fuel cost over steam or other known engines.

(2) Reduction in weight of fuel carried for same power, giving greater cargo space.

(3) The Diesel engine is relatively much more efficient than any steam engine in fuel consumption at low speed. This fact is of particular importance for vessels which run most of the time much below their full power and speed, such as war vessels, trawlers, coasting boats and boats on internal waterways.

(4) There are no stand-by losses, which may be an important point worth consideration when ships make frequent calls at ports.

(5) Fuel can be stored almost any place in vessel.

(6) Economy of space, and economy in weight of Diesel engines as compared with steam engines and accessories weigh on an average one ton to every 5 to 8 i.h.p. Diesel engines and accessories of slow speed type, that is, under 300 revolutions per minute, weigh one ton to every 10 to 15 b.h.p. For high speed types it is as much as 25 b.h.p. per ton.

(7) The reduction in staff, as no stokers are required.

Taking all the economies effected in weight of fuel, weight of machinery and engine-room space it may be safely estimated that the extra cargo which could be carried would be about 15% of the displacement of the vessel.

A comparative estimate has been made, showing that in a vessel of about 5,000 tons the net saving between Diesel engines and steam worked out over $5,500 per annum.

When a Diesel engine is installed in a vessel, the lines of vessel may be finer than if a similar powered steam engine were installed, still the most suitable speed of Diesel engines is, generally speaking, more than the most economical propeller speed. However, these two considerations about balance each other.

The ease and cleanliness in handling oil, as compared with coal, is another important point.

All the operations of the engine are under the eye of the engineer in the engine-room.

The absence of smoke is also noteworthy.

The initial cost of a Diesel plant is from 15 to 20% more expensive than a steam installation, including all auxiliaries in both cases, but it is to be emphasized that price-cutting would be a fallacy if the perfection of construction is to be maintained.

The Diesel engine can be used directly reversible or geared to propeller shaft.

There is a type of engine called the Semi-Diesel engine being used largely on cargo boats, barges and lake boats. This is an extremely simple engine, very reliable for class of boats stated above.

This engine compresses air alone and uses crude oil as a fuel. It operates on the two-cycle with crank chamber air compression. (See Fig. 6).

Air is drawn into the crank-case on the up-stroke of the piston through flap valves (B) on the side of crank case (C). This air enters the working cylinder (D) at the end of the down-stroke at (I), just after the expulsion of the exhaust at (G) from the previous power stroke. On the return of the piston this air is compressed still further to about 125 lbs. per sq. in. into a "hot bulb" (E) on the cylinder head. The charge of oil is then injected through (F) at the moment of maximum compression. The heat of the bulb automatically fires the mixture. This bulb is heated by a blow lamp for a few minutes before starting up.

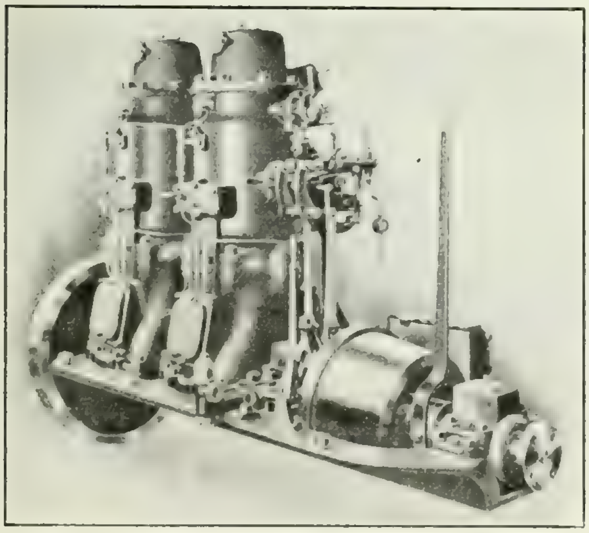

Fig. 5.—Direct Reversible Marine Engine.

It is one of the simplest and most reliable types of engines and shows almost equal economy of fuel. Initial cost is much cheaper for smaller powers than the Diesel.

Comparative Tables of Running Costs.
(Actual Log Book Figures).

Cents, per kilowatt hour generated.

Item.	Steam.	Producer Gas.	Diesel.
Fuel	1.78	1.74	0.60
Oil, waste, water, stores	0.24	0.38	0.06
Men's wages	0.64	1.36	0.34
Repairs and maintenance	0.74	1.60	0.16
Total operating costs per kw. hour generated	3.40	5.08	1.16

Load factor 12.45%, 16%, 14%.

The Birmingham Electric Tramways (England) show total operating costs in cents per kilowatt generated at switch-board to be .74 cents.

The Diesel engine should be of special interest to Canadians, as its fuel is more prevalent in Canada and easier to transport than coal. Value of crude oil at the oil fields is about $3.50 per ton. These are the so-called residual oils which are obtained by the distillation of the oil from the well, the lighter bodied oils, benzene and lighting petroleum coming over first and leaving a residual oil. Its specific gravity is about .87, and owing to its high flash point is quite unsuited for lamp oil. There are certain other oils which have been used on Diesel engines, and in particular cases may prove of great value. A Diesel engine has been working on ordinary coal tar as a fuel, so one can readily see that there are many liquid fuels available.

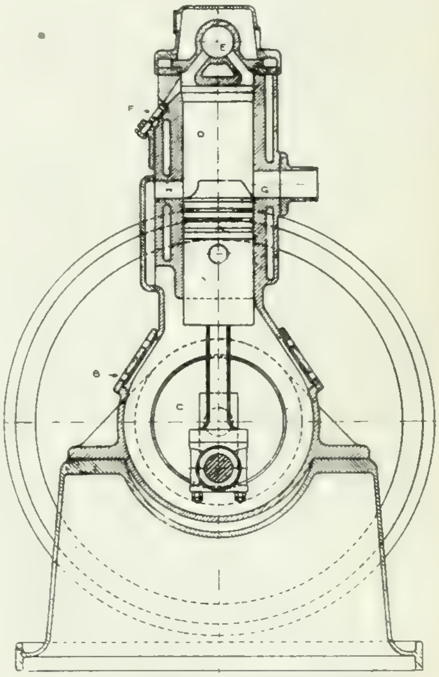

Fig. 6.—Section Through Direct Reversible Marine Engine.

◆

ELECTRIFICATION OF MELBOURNE SUBURBAN RAILWAYS.

Offers of a representative character, from the leading firms throughout the world engaged in the manufacture and supply of electrical machinery and equipment, are now receiving the attention of the government of Victoria, Australia, in view of the conversion of the Melbourne suburban railways from steam to electric traction. While no figures have yet been disclosed, it has been announced that the competition amongst the tenders has been very keen. The offers give the option of adopting either the single phase alternating current or the direct current system. This proposed change in traction will involve a huge expenditure in a suburban railway system which (excluding the extensive cable tramway service also in operation) carried 96,163,296 passengers last year. A leading English electrical engineer is now in Melbourne for a limited period for the purpose of giving expert advice to the government.

THE NEW LOCK AT THE SOO.

Coincident with the construction of large permanent steel ore docks at Lake Superior shipping ports, capable of accommodating the mammoth carriers recently built, provision is being made to facilitate the passage of such vessels through the channel at Sault Ste. Marie, where the existing locks are proving inadequate to the service. The principal work now in progress there is the building of the new Davis lock, recently described in the Mining and Engineering World, which was begun in March, 1907, and will not be completed until 1916.

Next to the Panama canal this is the most important aid to navigation now being carried out by the federal government; and it is due entirely to shipments of ore from Lake Superior ports.

The total length of the lock will be 1,715 ft. and its width 80 ft., 1,350 ft. being within the inner gates. Six culverts are provided for; 1,200 ft. of the wall is 50 ft. high and 26 ft. wide at the base. It is to be built up from bed rock in sections, alternate sections being constructed first and the intermediate sections later. They are 25 to 35 ft. in length. The concrete of the lock floors will be 1½ ft. thick. The work also includes lining about 325 linear ft. of tunnel rock, and the building of about 170 linear ft. of tunnel in trench, in addition to the tunnels and passages through the masonry. To furnish the crushed rock for the concrete work there has been built for the concern having the complete contract, viz., the Great Lakes Dredge and Dock Co., the plant described in the following. It is located in the vicinity of the new lock.

This plant is designed to crush Lake Superior trap rock. There are two gyratory breakers. One is a No. 7½ machine, with receiving opening 14 by 52 ins. set to crush to 3½-in. cubes, and the other is a No. 5 breaker with 10 by 38-in. opening which makes a 2½-in. product. Their foundations are flush with ground level, or about 8 ft. above the normal water line. Both machines are fitted with manganese mantles and [illegible].

The discharge from the breakers is taken by a No. 7½ continuous bucket elevator, with centres 68½ ft. apart, and discharged to a 48-in. by 16-ft. iron-frame, revolving screen. From this the oversize rejections are returned through a spout to the No. 5 breaker, while the screen product falls to a storage bin, of heavy-timber construction, set 12 ft. above the rails of the 36-in. gauge loading track. This bin is 16 ft. wide, 48 ft. long and 21 ft. deep, with steel-rod partitions and suitable discharge gates in the bottom.

There are also provided two troughing-belt conveyers, [illegible] supported on light wooden trestles, which have ⅛-in. rubber covering on their [illegible]. By these the [illegible] can be diverted, as required, and borne to two stock piles, 60 ft. high, and [illegible]

[illegible]

[illegible]

provements that have been found necessary in the operation of the two locks now there. The length in use will not only be utilized in handling longer boats, as they are built from year to year, but it also will make possible the entry of two of the longer craft in tandem style, a practice never yet indulged in.

At present the two or more boats often passing the locks together are locked through abreast of each other. Vessel owners and masters declare this is a dangerous proceeding. The boats, they say, not only require more time to take their positions in the locks in this way, but also that there is great danger from suction to the boat remaining in the lock when the first one steams away.

On more than one occasion lines have snapped and boats have drifted temporarily in a helpless manner in the locks.

The present largest lock, the Poe, is 100 ft. wide. The new one will measure but 80 ft., making it impossible to lock vessels through in any other way than tandem.

Probably the most distinctive feature of the new lock will be its depth. When opened for navigation it will present a loading depth of 24½ ft., or 6½ ft. more than the present depth accorded the boats of the great lakes. While all channels on the lakes are now dredged to a depth of but 21 ft., experts declare it will prove of less expense to dredge the channels deeper than to construct or remodel other locks.

The practical value of the depth presented by the present locks, an average of 18 ft. is displayed in the trouble the larger boats experience in locking through. Unnecessary delay is now experienced by the masters in locking through by the upheaval of water at the bow of the boat. Such conditions, engineers say, are due to the excess of water caused by the entrance of the boat to the lock being unable to escape fast enough at the sides of the boat. With the additional depth presented by the new lock, this water, it is figured, will be forced under the boat to the escaping channels beneath the flooring. With such facilities at hand vessels will be able to lock through in less than half an hour, while it now takes many of the larger ones over an hour.

The importance of the work now being done by the federal government on the new locks and canal here, may be seen from the fact that the present locks already float the greatest commerce of any inland waters of the globe. In 1911 the total tonnage amounted to [illegible], which is two and one-half times greater than that passing through the Suez Canal, and seven times greater than that of the Kiel Canal. What the traffic will amount to with the addition of another lock, the greatest yet constructed, remains to be seen.

The present commerce exceeds that borne by all ships, British and foreign, entering the ports of Great Britain in one year, and valued at an average of $654,010,844 annually. When completed the new lock will not only be by far the largest in the world, but will represent an expenditure of about $9,000,000.

◆

PATRICIA LAND.

Mr. J. B. Tyrrell, who led the Government expedition to the Hudson Bay through the new district of Patricia, has returned to Toronto and commenced the preparation of his report to the proper authorities.

According to him there is a larger area of tillable land in this section than was at first supposed, and he is confident that the bog lands are so situated that their drainage is a simple problem. The best land in Patricia is forest covered, and other large stretches resemble Temiskaming, [illegible] in which hardly a clear acre of good soil may be found, alternate with large sections of promising land. Mr. Tyrrell states that this portion of the Dominion will some day be a sportsman's paradise, as the swamps teem with flocks of wild ducks and the rivers abound with fish.

TEN THOUSAND HORSE-POWER HIGH-PRESSURE TURBINES FOR THE BIASCHINA ELECTRIC POWER STATION.

The Biaschina electric power station near Bodio, Northern Italy, built by the A. G. Motor, utilizes the water of the River Tessin, with its tributaries, with a total head, between the Gotthard Railway stations of Lavorgo and Bodio, of 840 feet.

The water intake is located 500 feet down the valley from Lavorgo Station, on the right bank of the River Tessin, where the water is diverted by means of an overflow weir, built slantingly across the river. The water is then conducted to a special filtration reservoir, where it is cleared of any deposits of sand or other impurities; from here a closed canal of about 5½ miles length takes the water to the forebay, from which the water is led to the four turbines, each consuming at a head of 840 feet about 138 c.f.s.

The upper portion of the feeder conduit is in the form of a pressure tunnel, which at the point where the pressure reaches 260 lbs. per sq. in. is connected up to two separate steel pipe lines of about 67-in., inner diameter.

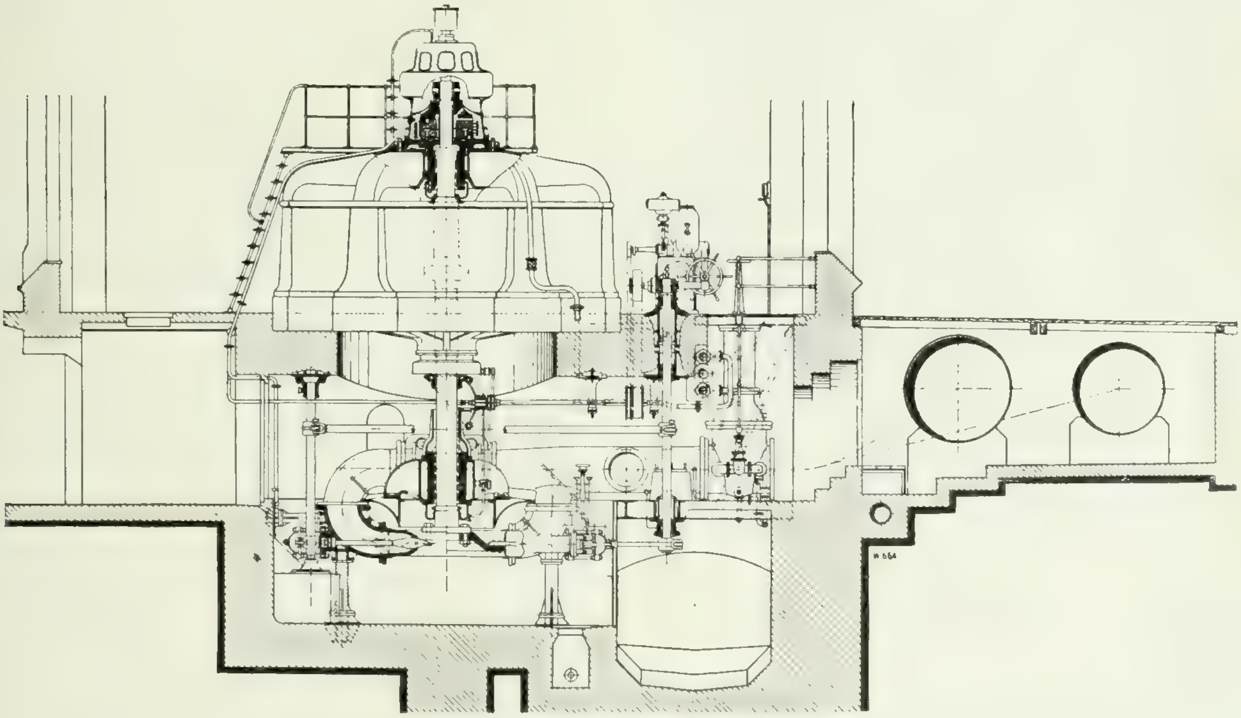

Fig. 1—Longitudinal Section through 10,000 H.P. High-pressure Turbines.

Each of the two pipe lines delivers the necessary amount of water required by two high-pressure impulse wheels, each capable of developing an output of 10,000 horse-power when running at 300 revolutions per minute. However, in accordance with the specifications, each of the wheels is designed so as to yield a maximum power, at full opening, of 12,000 horse-power.

For various reasons the vertical shaft arrangement was given the preference over the horizontal type, following recommendations made by Escher Wyss & Co., as similar turbines running on a vertical shaft designed and constructed by the same firm had given great satisfaction. The accompanying cuts show the general design of this type of turbine. The initial installation consists of three units with a total maximum output of 36,000 horse-power.

The two inlet pipes for each turbine are arranged symmetrically to the turbine axis, and are connected to the main pipe lines at an angle of 90°. The hydraulically operated gate-valves of 24-in. diameter are located inside the power-house, near the wall. These valves may be opened or closed from the machine house floor by a hand-wheel controlling an intermediate distributing valve, which directs the pressure water to the servomotor, or pressure cylinder, accordingly. In front of each valve an expansion piece is fitted in order that, in case of repairs, the valve may be quickly and safely removed.

The total power of 12,000 horse-power is developed by only one single runner wheel fitted with double pear-shaped buckets of cast-steel mounted around the circumference of the wheel. The water is discharged under full pressure of 840 feet through four needle nozzles, forming a circular solid jet, which again impinges upon the buckets of the runner. The nozzles from which the water is escaping with a velocity of 220 feet per second are most carefully designed and supported in such a way that the forces originating from the reaction of the water cause least possible vibration.

The governing mechanism for controlling units of this large capacity requires to be designed most carefully in order to safeguard the operation of the machines in cases of sudden changes of load. For this plant Escher Wyss & Co.'s patent Universal oil-pressure governors have been installed. Their oil-pressure pumps and speed pressure and speed pendulum are driven by belts off a transmission shaft situated underneath the power-house floor. The governor is usually operated by pressure oil, but each governor is also provided with a hand-wheel, so that the whole unit may be temporarily controlled by hand. The servomotor of the governor operates the vertical main regulating shaft, which latter, by means of a system of levers and rods, is connected up to the needle nozzles; the regulating needles are consequently controlled directly by the governor. These needles are so designed that they, in any position, are practically balanced, so that the capacity of the governor might be reduced, and also a most even working of same is obtained. The various pins and joints are provided with bearings on both ends, designed for grease lubrication, so that the wear and friction is reduced to a minimum. From the servomotor each nozzle can be adjusted according to the load under which it is to work, and it is also possible, if necessary, to entirely close two or more of the nozzles of each unit.

All bearings, not only those of the main shaft, but also those of the transmission gear and regulation shafts, are fitted with removable babbitted bearing bushes. The shafts are provided with continuous ring oil lubrication, except that the governing shaft, the movement of which is limited, is lubricated by grease. The oil-pressure thrust bearing, which carries the total weight of the rotary parts (about 100,000 lbs.) is placed on the generator frame. On top of this the exciter stator is mounted.

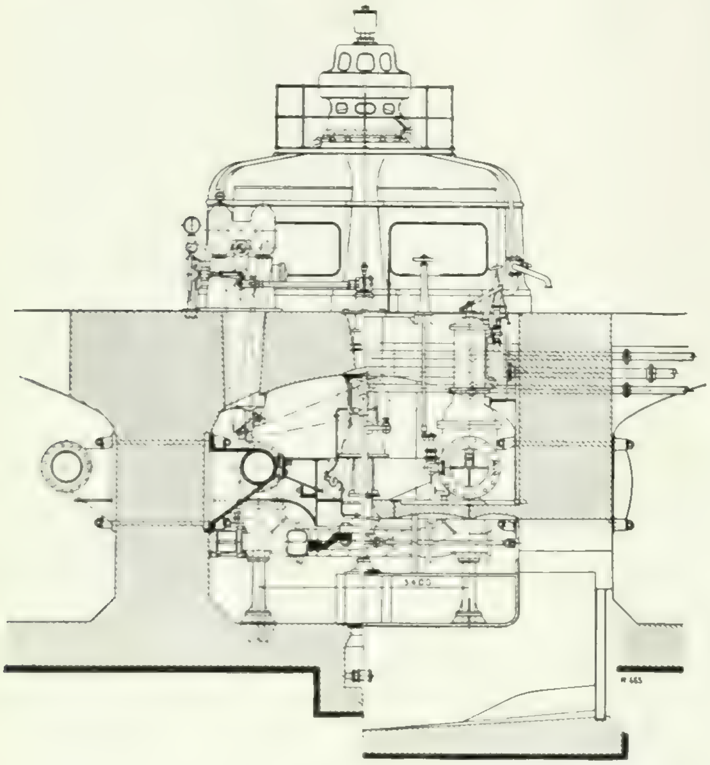

Fig. 2.

An oil-pressure plant has been installed for the special purpose of balancing and lubricating the thrust bearing.

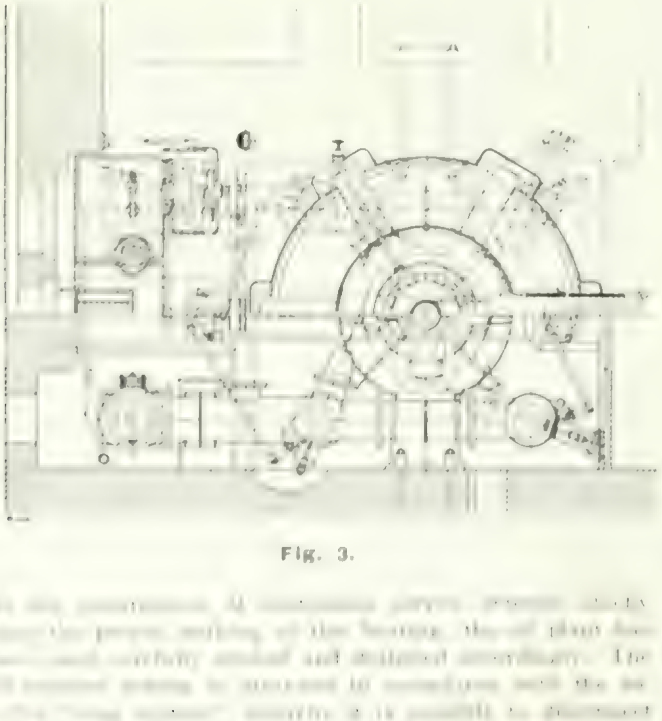

Fig. 3.

[illegible] the maintenance of continuous proper pressure [illegible] upon the proper working of the bearing, the oil plant has been most carefully studied and designed accordingly. The oil-pressure piping is arranged in connection with the so-called "ring system," whereby it is possible to disconnect any one of the four units without having to stop any of the other machines. There art two pumps, of which one always is kept in reserve. Both are of the Escher Wyss & Co. type, and each is driven by gear from a separate impulse wheel of about 30 horse-power. In the basement, immediately beneath the pumps, two oil reservoirs with a capacity of about 1,750 gallons have been provided. The two reservoirs are so connected one to the other that it is possible for any pump to take oil from either of the reservoirs. Each pump is also fitted with an air-chamber; the air for the latter is furnished by the sniffing cock, which is mounted on the air-chamber so that the oil may not be mixed with the air.

In order to be able to undertake repairs in the turbine pits also without having to shut down the whole plant, arrangements have been made so as to separate the various chambers by water-tight partitions. For emptying these chambers, each has been fitted with an injector with which it is possible to drain about 2,200 gallons of water per hour. The necessary pressure water for this purpose is tapped from the pressure pipe line, and in such a way that should one or the other pressure pipe line not be working, any of the chambers can still be emptied.

◆

A RARE OCCASION.

By James Hedley.

Detroit River has been, within the past few days, the scene of an event celebrated in an unusual way. This event is the completion of the Livingstone Channel, excavated to a depth of 23 feet and a width of 400 to 600 feet for thirteen miles into the head of Lake Erie, six miles of this distance being through solid limestone, known as the Limekiln Crossing of Detroit River. This work is one of the wonders of science and enterprise, undertaken by government at a cost of $10,000,000, and all of it paid by "Uncle Sam" except a few hundred thousand contributed by the Canadian Government.

So greatly is this boon to navigation prized by the Lake Carriers' Association and by the marine and commercial men of the inland States and Canada, that its practical completion is signalized by a procession of steamers upon a great scale. Yachts, ferries, passenger boats, revenue cutters, motor boats and great, modern freighters, from 400 to 600 feet in length, passed through this enormous cut, first downward with the current, then back to Detroit, 22 miles, to the accompaniment of flags, bands, siren whistles and the shouts of thousands of spectators, assembled from the lake cities. One steamer, the "Britannia," carried 1,700 guests. The great steel steamer, "William Livingstone," appropriately named, as the channel is, after the president of the association, an indomitable pioneer in the modern improvement of the Great Lakes waterways, headed the procession.

Work was begun on this important achievement in the spring of [illegible] when the contractors began the huge cofferdam which enclosed what is known as the dry work section, about [illegible] mile of the river bed near the upper end of the [illegible]. Actual channel digging was begun in the fall of the same year, after powerful steam pumps had drained that part of the river bed enclosed by the dyke. Of the four contracts let, Nos. 1 and 2 were to Chicago parties. Section 3, about [illegible] feet in length, was completed by McNaughton & O. J. Dunbar, of Buffalo, and Section 4, in Lake Erie, [illegible] feet by G. H. Breymann & Bro., of Toledo.

MEASUREMENT OF ACTUAL STRESSES IN REINFORCED-CONCRETE STRUCTURE.*

By W. K. Hatt.†

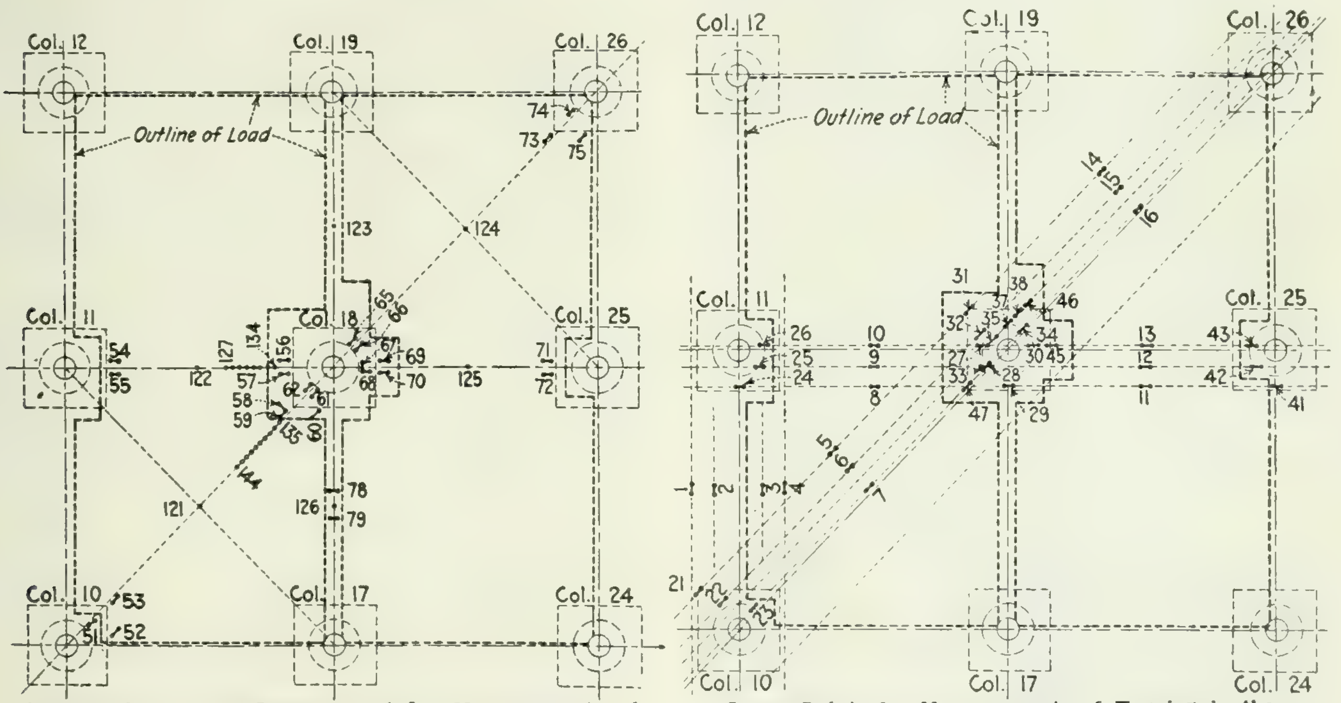
This paper is mainly an account of the general features of a test of a reinforced-concrete floor of flat-slab construction. The full report of the test with all pertinent data was made to the Leonard Construction Company, Chicago, which has permitted the writer to use the report as a basis for this paper.

Nature of Tests.—In brief, the floor was loaded with pig iron in increments, and the accompanying deformations were measured in the steel and in the concrete at all critical points, with a view to fixing a safe limit of loading and to understanding the mechanical action of the structure.

The Structure Tested.—The building tested is the Franks Building, Chicago, Ill., a 10-story-and-basement warehouse used by the printing and paper trades and the type of construction used was the "Cantilever Flat Slab" system. The design load on the floors was taken at 250 lb. per sq. ft. The panel dimensions were 19 ft. 4 in. by 20 ft. 3 in.

The four panels under observation were in the interior of the building, and on the tenth floor, where the columns were of minimum size. As the effective clear span and the eccentricity of column loading were the greatest, the location was such as to insure the most severe test possible.

The diagonal reinforcement was eighteen ½-inch round bars, 40 feet long, spaced 5⅝ in. on centres. The cross bands were composed of sixteen ½-inch round bars 44½ feet long, spaced 6⅜ in. on centres. The slab thickness was 9¼ inches, increased to 13¼ inches near the columns. The concrete mix was 1:2:4 in the floors and 1:1:2 in the columns.



Gauge-Points for Deflections and for Measurements of Compression in Concrete.

Gauge-Points for Measurements of Tension in the Slab Steel.

Fig. 1.—Locations of Gauge Lengths for Steel and Concrete Stresses, and Points at Which Deflections were Measured.

Methods of Observation.—The observations were made by experienced observers: Prof. H. H. Scofield, of Purdue University, and Prof. W. A. Slater and W. E. Ensign, of the University of Illinois Engineering Experiment Station, with the assistance of Prof. L. W. Weeks, of Purdue University.

The deformations were determined by the use of extensometers of the type devised by Prof. H. C. Berry, of the University of Pennsylvania, a former pupil of the writer at Purdue University. On the steel a gauge length of 10 in. was used, which, with the multiplying lever in the instrument, gave direct readings of unit deformations of 0.00002 in. per in., corresponding to stresses of 600 lb. per square inch in the steel, and it was possible to estimate clearly fractions of this amount. For the concrete readings the gauge-length was 6 in., and the direct reading of unit deformations was 0.000033 in. per in., corresponding to a stress of 133 lb. per square inch, and it was possible to estimate fractions of this amount with accuracy.

Errors in operating the instrument were reduced to a minimum by taking every reading at least five times, and by calibrating on a standard bar at frequent intervals. Four standard bars were used throughout the test, all of these being embedded in the concrete and subject to the same temperature changes as the rods in the test floor, but free from any stress due to applied load. By reading on these bars between sets of five or six test readings, the observations on the materials under test were freed from errors caused by temperature differences and from systematic errors.

Deflections were measured to 0.0001 in. by use of the deflectometer described in a previous test for actual stresses.

Tensile deformations were measured throughout the test over 42 gauge-lengths on the steel reinforcing rods. Compressive deformations in the concrete were measured over 26 gauge-lengths. Deflections were observed at 24 points. Also, 27 other readings of deformations were taken throughout the test, to study such phenomena as the arch and slab action, the distribution of stress, and the eccentric loading on the columns at the edges of the loaded area. The locations of the various gauge-lengths are shown by the two diagrams Fig. 1; see, also, the view Fig. 2.

The observations were arranged in groups, each designed to cover adequately some particular feature, and symmetrically located observations were obtained as a check in every case where possible, in order to cover variations in the quality of the concrete at different points.

---

* A paper read before the Indiana Engineering Society.

† Professor of Civil Engineering, Purdue University, Lafayette, Ind.

It should be remarked that the results from the use of the Berry extensometer are reliable only after the observer has had considerable preliminary practice with this instrument. The holes in the steel bars must be carefully reamed, the instrument must be protected from the heat of the hands, and the contact points must be seated under uniform pressure. Observance of these requirements, multiplied observations, and frequent reference to the standard calibration bar, are the conditions of success.

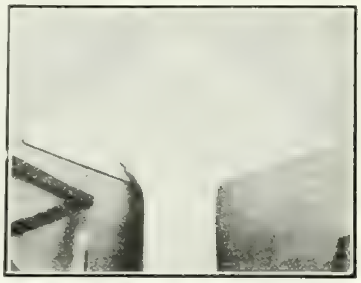


Fig. 2.—View of Slab from Below, Showing Column Capital and Several of the Gauge-Points.

(At the time these pictures were taken the four panels shown carried 20 % overload)

The conditions were exceptionally favorable to a satisfactory test. The building was practically completed at the time of test. The temperature varied but little, being about 74° at the start of the test, dropping gradually and uniformly to 70°, and rising again at the end to 74°. The slab was poured on June 23, 1911, and was 64 days old when the maximum load of 624 lb. per sq. ft. of panel area was placed upon it.

Loading.—The amount of loading was determined by the weight of the pig iron as recorded on the weigh bills delivered by the teamsters, and was checked by weighing a number of piles of pig iron from the test load on a platform scales.

The pig iron was piled on the floor in separate piers, each placed within a 2-ft. square, so that no arch action existed in the load itself to relieve the panel from movement. It was necessary to leave several of these squares vacant about columns and to leave an aisle between the columns to allow space for observations. (See view Fig. 3). The pig iron belonging on these vacant squares was distributed over the remaining squares of the same panel. It will be apparent that under this procedure the real load intensity, as affecting bending stresses and deflections, is the intensity of load [illegible] over the loaded area (about 90% of the panel area), rather than the nominal or average load over the entire panel area.

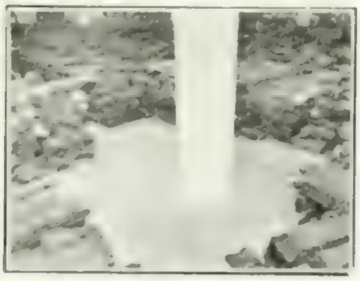

Fig. 3. View of Slab with Pig-Iron Loading, Showing Space Left for Making Readings.

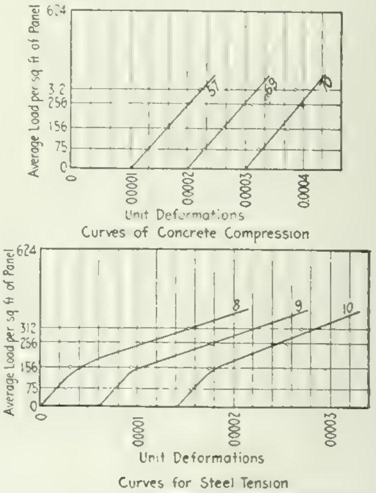
[illegible]

[illegible] Readings were [illegible] taken with 312 on the [illegible] diagonal panels and 156 on the others, but without waiting for the six-hour interval to elapse before taking readings.

The total number of complete observations over single gauge-lengths was over 2,000, and the total individual readings over 10,000. The test occupied one week's time.

Stresses.—The stresses were determined from the observed deformations by using a modulus of elasticity of 30,000,000 lb. per sq. in. for the steel, and 4,000,000 lb. per sq. in. for the concrete. The latter value was determined from tests of three concrete prisms poured from the concrete in the test slab and tested at Purdue University at an age of 77 days.

Load-deformation curves were plotted for each observation point, the known nature of the curve under flexure being used as a basis; typical curves are shown in Fig. 4 herewith. The dead-load stress has been taken from these curves as equal to the stress caused by an equal live load.



Curves of Concrete Compression

Curves for Steel Tension

Fig. 4.—Typical Load-Strain Curves from Tests in Franks Building.

The table below gives a summary of the corrected values of the total dead- and live-load stresses found from the various groups of observations. The detailed summary of individual stresses at the various observation points is omitted in this paper.

Comments on the Results.—The writer is not prepared at the present time to state the significance of the results obtained with respect to the mechanics of this form of construction. Such statements would be somewhat speculative, and should be separated from the report of test, which is one of measured facts.

The Slab Design.—As compared with the design requirements of the Chicago Building Code, it is interesting to note that at design load the highest average stress in the steel is [illegible] lb. per sq. in. (average of observations 11, 12 and 13), while the highest average compressive stress in the concrete is 677 lb. per sq. in. On the basis of safe working stress in the steel of 16,000 lb. per sq. in., and in the concrete of 35% of the ultimate strength (which averaged [illegible] by tests of prisms) or 1,100 lb. per sq. in., it appears that the steel is stressed to 31% of its safe load, while the concrete is stressed to 62% of its safe load. It

Table of Actual Stresses Observed in Test of Franks Building.

All stresses are the final values for total dead and live load, and are given in pounds per square inch

Average of Observations Nos.	Description	Live load lb. per sq. ft. 256	312	624
STRESSES IN SLAB RODS				
5, 6, 7, 14, 15, 16	Center of span, diagonal band	1071	1920	6050
8, 9, 10, 11, 12, 13	Center of span, cross band	4549	6140	[illegible]
41, 42, 43, 44, 45, 47	Over capital at center column, diagonal band	3140	1350	9280
27, 28, 29, 30	Over capital at center column, cross band	1575	1840	8140
[illegible]	Over capital at corner column, diagonal band	1920	2780	7540
24, 25, 26, 41, 42, 43	Over capital at side column, cross band	2090	3138	5815
COMPRESSIVE STRESSES IN CONCRETE				
56, 57, 58, 61, 65, [illegible] 70	On slab at center column	500	650	1906
[illegible] 62, 65, 66	On drop at center column	677	778	1085
[illegible]	On drop at corner column	418	[illegible]	1515
[illegible]	On slab at corner column	129	[illegible]	650
[illegible] 73	On slab at side column	180	217	[illegible]
MAXIMUM BENDING STRESSES IN COLUMNS				
[illegible]	Compression in concrete, corner column	[illegible]	540	1000
[illegible]	Compression in concrete, center column	116	[illegible]	1000
[illegible]	Tension in steel, corner column	[illegible]	6000	[illegible]
[illegible]	Tension in steel, side column	[illegible]	[illegible]	[illegible]
DEFLECTIONS IN INCHES				
[illegible]	Center of panel at 6 hours	0.103	0.156	0.475
	Center of panel at 24 hours			0.500
	[illegible] 6 hours	0.11		
	[illegible] unloaded 14 days	0.06		

[illegible] pounds per square foot were on four diagonal panels. The [illegible] two panels adjacent [illegible] appears, therefore, that the design is overbalanced with an excess of steel. At the highest applied load of 717 lb. per sq. ft. the ratio of the steel and concrete stresses remains practically unchanged.

Column Bending.—The eccentric action of the test load was most marked on the corner columns of the loaded area, and was sufficient to produce a tension in the steel of 4,980 lb. per sq. in.

With respect to the strength of the structure, it may be said that a nominal load of 624 lb. per sq. ft. of panel, which actually was 717 lb. per sq. ft. of loaded surface, was applied without producing any permanent damage to the building. At this load the highest observed average total dead- and live-load stresses were less than 12,000 lb. per sq. in. in the steel and less than 1,700 lb. per sq. in. on the concrete.

◆

IRON AND STEEL PRODUCTION IN CANADA.

The American Iron and Steel Association has compiled from returns furnished direct by makers the following statistics of the output of finished iron and steel in the Dominion:—

Finished Rolled Iron and Steel.—The production of all kinds of finished rolled iron and steel in Canada in 1911 amounted to 775,424 tons, as compared with 739,811 tons in 1910, an increase of 35,613 tons, or over 4.8 per cent. Of the total production in 1911, 86,383 tons were iron and 689,041 tons were steel, against 83,918 tons of iron and 655,893 tons of steel in 1910. The following table gives the production of leading articles of finished rolled iron and finished rolled steel in Canada in the last three years in tons (2,240 lbs.). The production of one plant has been estimated for 1910 and 1911:—

	1909. Tons.	1910. Tons.	1911. Tons.
Rails	344,830	366,465	360,547
Struct. shapes and wire rods	74,136	80,993	76,617
Plates and sheets	36,241	26,642	14,833
Nail plate, bars, etc.	207,534	265,711	323,427
Total	662,741	739,811	775,424

Forged Iron and Steel.—The total production of forged iron and steel by rolling mills and steel works in Canada in 1911 amounted to about 18,832 tons, of which about 787 tons were iron and about 18,045 tons were steel. In 1910 the production of forgings amounted to about 18,165 tons, of which about 1,258 tons were iron and about 16,907 were steel.

Cut Nails and Wire Nails.—In 1911 the rolling mills and steel works in Canada which operated cut nail or wire nail factories produced about 652,861 kegs of steel cut nails and steel wire nails of 100 lbs. each, as compared with about 327,580 kegs in 1910, about 374,100 kegs in 1909, and about 298,000 kegs in 1908.

Active Rolling Mills and Steel Works.—In 1911 there were 27 works in six provinces which made steel ingots or castings, or rolled iron or steel into finished forms, against 24 works in six provinces in 1910, a gain of three works. Of the total in 1911 there were 21 works which rolled iron or steel into finished forms and six which made steel ingots or castings but not finished forms of rolled iron or steel, while in 1910 the number of works which rolled iron or steel into finished forms was 20 and the number of works which did not roll finished forms was four. In 1911 there were four idle rolling mills and steel works, against three in 1910.

Of the 27 active rolling mills and steel works in Canada in 1911, six were located in Nova Scotia, six in Quebec, 11 in Ontario, two in Manitoba, and one each in New Brunswick and British Columbia. On December 31st two plants were being built in the province of Quebec.

ELEMENTARY THEORY AND PRINCIPLES OF STREET CLEANING.[*]

By S. Whinery, Consulting Engineer, New York City.

The cleaning of city streets is necessary for reasons which may be summarized as the preservation of the public health, the physical comfort and convenience of the people, and a regard for decent cleanliness and good appearance. Of these, the preservation of the public health must be considered of first importance.

Filthy streets have long been held by sanitary authorities to be a prolific cause of disease, but our views as to the exact way in which street filth causes or propagates disease have, in the light of more recent investigations and conclusions, undergone a notable change. The prevailing idea in the past among sanitarians and physicians, as well as in the public mind, has been that filth and organic matter in the process of decay give off poisonous gases or exhalations capable of conveying, if not of creating, various diseases in the bodies of those exposed to them. Thus, it was held that the effluvia from sewers entering dwellings through untrapped pipes and fixtures was the direct cause of much sickness.

More recent investigations and the development of the germ theory of diseases lead to the conclusion that a large number, if not all, of the infectious or contagious diseases that affect mankind are caused, directly or indirectly, by specific organisms which propagate and multiply in the blood, and that these organisms or their germs are carried into the body not by gaseous exhalations, but only by solid or fluid matter with which the germs are incorporated or to which they are attached. These conclusions have an important bearing upon the theory and practice of street cleaning.

From the sanitary point of view street dirt may be divided into two physical classes or forms: first, the comparatively fresh, coarse and recently deposited material, such as animal excrement and the usual refuse matter and rubbish that reaches the streets; and second, the finely comminuted matter, which, when dry, is called street dust.

The first, especially when damp, possesses sufficient ponderability to prevent its being taken up and carried by ordinary currents of the air. In the second form named, that of dust, street dirt is, from the sanitary standpoint, wholly different from the first.

When the coarse material reaching the street is not removed with reasonable promptness it is subjected to the drying effect of the sun and air and to the pulverizing action of travel, and is thereby reduced to a condition of powder so fine and light that it readily floats in the air when disturbed, and may be carried by winds or breezes to considerable distances. While thus suspended in the air it may be breathed into the lungs or deposited upon the bodies of those in the vicinity. Assuming that this street dust is infected with disease germs, it is obvious that the conditions could not be better for disseminating them and conveying them into susceptible human bodies.

If the views here outlined are accepted as true, they indicate that important changes should be made in the present practice of street cleaning. Efforts should be more particularly directed, first, to preventing the formation of street dust; and second, to the removal by efficient methods and in a manner that will prevent unnecessary dissemination of such dust as may be unavoidably formed.

Heretofore in American cities the principal object has been to remove the coarse street dirt at such intervals of time as convenience or necessity might dictate by methods and apparatus not well adapted to removing the dust, which was largely allowed to remain on the street. If the quantity of dust became sufficient to cause discomfort when blown about by the winds, the streets were sprinkled with water to lay the dust. This was a palliative only, since but a small part of the dust was washed into the sewers and the remainder was left on the street to be again converted into dust when the intervals between sprinkling were long enough to allow the moisture to evaporate. Until quite recently the streets in all our cities were cleaned almost exclusively with coarse-fibre street brooms or the horse-power sweeping machine, and this practice still largely prevails in most cities and towns. As a means of removing the coarser dirt these methods are reasonably effective, and would be quite satisfactory if the sweeping could be done at sufficiently short intervals. But where the streets of heavy travel, and consequently of large accumulations of refuse, are swept but once daily, or at longer intervals, and usually at night, the heat and travel during the day are sure to convert much of the dirt into dust which the coarse-fibre brooms stir up but do not satisfactorily remove.

---

[*] Abstract of a paper read before the American Public Health Association, September, 1912.

It is true that the sweeping machines are usually preceded by the sprinkling wagon for the purpose, mainly, of preventing the clouds of dust that would otherwise be raised to the annoyance of those exposed to it, rather than to facilitate the removal of dust from the street. If not enough water is used to just moisten the dust and cause it to adhere and aggregate, most of it will remain on the street, while if too much water is used the dust is converted into a paste, which the brooms plaster upon the street surface to again be converted into dust under the action of [illegible] travel.

For the purpose of removing the coarse accumulations, patrol or hand-cleaning with broom or scraper, or both, is most efficient and satisfactory. This is true if for no other reason than that the dirt is more promptly and frequently removed. The cleaner passes over his beat several times during the day and thus removes the refuse before it has had much time to dry out and become pulverized.

For the removal of such dust as cannot be prevented, the only effective and satisfactory way yet developed is to wash the surface with water. This may be accomplished either by the use of machines of the squeegee type, which scrub the surface, or by flushing with water under pressure [illegible] carry away the fine material. For the latter either flushing machines or hose attached to fire hydrants are available.

[illegible] the removed dust into the sewers or drains, which is regarded by many as objectionable, and as likely to clog the [illegible] dirt, coarse and fine, is thus carried together into the [illegible]

[illegible]

volume of water used tends rather to flush and clean out the sewers.

If the views here outlined are sound, the theory and controlling principles of street cleaning may be summed up as follows:—

First—Street dust is the form in which street dirt is the most dangerous to the public health.

Second—From the sanitary point of view, therefore, the most important function of street cleaning is the prevention of the formation of street dust and the prompt and safe removal of any such dust as may accumulate on the streets.

Third—To prevent the formation of dust the coarse and usually most excrement and refuse should be collected and removed as effectually and as frequently as practicable, before it becomes dried and pulverized. The most effective and satisfactory way of doing this is the patrol or hand-sweeping method.

Fourth—For the removal of the dust that will accumulate to some extent, scrubbing or washing the street surface with water is the only practical and effective method yet devised.

The ideal system of street cleaning would, therefore, be efficient patrol or hand-cleaning through the day, or during a longer period if the volume of travel in the evening requires it, and thorough scrubbing with squeegees, or washing with water under pressure by flushing machines or hose at night, as often as may be necessary.

It may be objected that the funds at the disposal of the street cleaning departments of most cities would not permit the adoption and adequate application of this system in many American cities. To this it may very properly be answered that in matters seriously endangering the public health the question of cost should not be controlling, unless that cost be absolutely prohibitive, or wholly out of proportion to the benefits that would result.

Actual experience, however, seems to prove that the method here recommended need not be so expensive as to be discouraging.

The streets of Washington are notable for their cleanliness. The method here recommended has been in use there for nearly two years with most satisfactory results both as to effectiveness and cost. In the report of the Street Cleaning Division for 1911 it is stated that in the neighborhood of 1,000,000 sq. yds. of street surface were cleaned every day except Sundays and holidays by the patrol system. The hand-cleaning was supplemented by washing the surfaces about one and one-half times each week. The report states (see Report of Street Cleaning Division, [illegible]):

"Under the above system of street washing it is found that the streets are almost entirely free from dust. Any dirt which may accumulate does not have time to be pulverized, and the particles are too heavy to be disturbed or blown about by an ordinary wind. Under the old method of sweeping these heavier and coarser particles were removed, but most of the dust remained to become a source of annoyance when disturbed by the wind or rapidly passing vehicles, although the streets might have appeared to the eye to be clean."

The cost of the work per 1,000 sq. yds. cleaned once is stated to have been as follows:—

Hand-cleaning, patrol system	$[illegible]
Washing by squeegees	[illegible]

But as the washing was done, on an average, only one and one-half times per week, the sum of the above figures does not give the correct average cost, which, for 1,000 sq. yds. cleaned once during a week (six days), may be arrived at as follows:—

Hand cleaning, 1,000 sq. yds. daily equals 6,000 sq. yds. per week at 17.53 cents per	$1.052
Washing with squeegee 1,000 sq. yds. 1½ times per week, equals 1,500 sq. yds.	0.1743
Total for combined cleaning once of 6,000 sq. yds. of street	$1.1795
Equal to a cost per 1,000 sq. yds. cleaned once of	0.1966

This figure seems very low, and probably could not be duplicated in many other cities where the business streets carry a much heavier travel, but it proves that this system of cleaning need not be unusually expensive.

The cost where the flushing machines were used is reported to have been 31.57 cents per 1,000 sq. yds. cleaned once. Assuming that the streets were flushed one and one-half times per week, as in the case of the squeegee, the cost of the combined cleaning once of 1,000 sq. yds. will be found to be 25.42 cents, which must still be regarded as a very reasonable figure.

It should be noted, however, that in neither case do these figures of cost include the value of the water used for washing. The quantity of water required per 1,000 sq. yds. cleaned once as determined by trials in New York, is about 150 gals. for the squeegee and about 470 gals. for the flushing machines; but the cost of this water would be offset, in a measure at least, by the cost of that which would otherwise be used for supplemental sprinkling where the ordinary sweeping machine is used.

SLUDGE ACCUMULATIONS AT SEWER OUTFALLS.

The subject of the relation of sludge deposits to nuisance was discussed by Mr. Langdon Pearse, assistant engineer, Sanitary District of Chicago, at the recent meeting of the American Public Health Association in Washington, D.C.; the paper, slightly condensed, is given below.

The sludge nuisance in the Back Bay Fens in Boston, as reported by Mr. John R. Freeman to the Charles River Basin Commission in 1903, was so marked and the deposits of sludge so large for a small stream (amounting to one-fourth the entire capacity of the basin) that extensive dredging and the removal of the sewage by means of sewer extensions was recommended. In the case of the Providence River in Rhode Island, dredging has relieved conditions. No exact measurements or details, however, have been given.

In the report of the Sanitary District of Chicago, October, 1911, Mr. George M. Wisner, the chief engineer, has described conditions of the fill in the Main Channel of the Sanitary District and given analyses of the same. The anlytical data show a rather heavy material compared to the sludge found in sewage disposal plants, resembling more nearly a grit-chamber sludge than a true sewage sludge. The effect of the sludge on the water passing above in the canal is detrimental, although quantitatively difficult to express. From the most marked sludge deposits just above the power house, considerable ebullition of gas occurs in the summer, and even in the winter, which helps in maintaining the oxygen content at a very low level. In portions of the canal near the city, studies have been made on the distribution of oxygen in the cross-sections, and a difference has been noted between the content at the top and the bottom, the bottom usually being lower. Some variation has also been found between the two banks before mixing is complete, a distance of four to five miles. Where the oxygen content is low the distribution through the section is practically uniform, complete mixing having taken place.

The presence of large sludge deposits and scum in the arms of the Chicago River, known as the Stock Yards slip or Bubbly Creek, is responsible for a condition of nuisance and degree of odor which might not occur to such extent could the suspended matter be kept moving and even partially oxygenated. Dredging has been carried on at times.

In New York harbor, reference has been made to sludge deposits in the report of the Metropolitan Sewerage Commission, and comment has been made on the indications of oxygen in the lower layers of the water through the presence of a reddish surface on the black sludge. This phenomenon indicates the oxidation of the ferrous sulphide. This has also been observed in experiments in the laboratory of the Sanitary District of Chicago, where several inches of sludge were placed in the bottom of shallow jars, the liquid above containing oxygen.

A few quantitative experiments, made by Mr. H. W. Clark, are given in the report of the Charles River Basin Commission, 1903, in which two grams of mud or sludge were placed in ½-gal. bottles full of fresh water, or salt, and the reduction of oxygen was followed. In five days the oxygen in fresh water was reduced to an average of 61 per cent. saturation from an initial complete saturation, the extremes being a reduction to 81 and 33 per cent. saturation. An experiment was also made, with continuous flow, using 9 in. of mud in a tank 12 ft. deep, the liquid being at first 5 and later 7 per cent. sewage. In general the surface layers contained more oxygen. Comment is also made on the production of odors in tidal waters by bacterial reduction of the sulphur compounds in sea water. In the examination of the conditions in the Fens basin, referred to previously, it was found that hydrogen sulphide was formed which rose through 6 ft. of water. No oxygen was found below a surface layer 6 in. deep.

On the absorption of oxygen by sludge, some comments have been given by Mr. Almon L. Fales, supervising chemist of the Sewer Department in the city of Worcester, Mass. In 1903 he conducted some experiments on the aeration of sludge and liquid in a tank holding 1,500 gals., and found that in the early period of the experiments it was necessary to aerate several times a day, but later once in 12 hours proved sufficient. It was also observed that the dissolved oxygen disappeared much more rapidly in the layer just above the sludge. Occasionally after 12 hours or less had elapsed after aeration the dissolved oxygen would be exhausted in the layer just above the sludge, while the top liquid would still contain as high as 25 per cent. saturation. After the experiments had been continued for three weeks it was found that the liquid just above the sludge lost all dissolved oxygen in 24 hours, while the top liquid showed 125 per cent. saturation. The super-saturation was caused by the propagation of chlorophyl containing micro-organisms which gave the liquid a greenish tint. Similar phenomena can be noticed at times in streams of intermittent flow where the dilution is not sufficient to prevent nuisance.

In shallow, wind-swept waters, sludge deposits may prove a greater source of odor, owing to the constant agitation of the waves. An experiment has shown that any disturbance of sludge under water is undesirable from the standpoint of prospective odors.

Of the remedies at hand, dredging seems to be in general but a temporary expedient, aside from its value in cleaning up offensive conditions. Unless a hydraulic suction dredge be used and large space be available for the ponding of the sludge, it may be difficult to remove all the material which should be classed as sludge. With a dipper dredge probably only the more gritty material would be removed, although conditions may be much improved thereby. The composition of sewage sludge, as found in sedimentation tanks of various types, ranges from a specific gravity of 1.01 to [illegible], and seldom exceeds 1.10, the water content running from 85 to 95 per cent. This is a material which is fairly liquid.

The only permanent remedy, Mr. Pearse states, is to prevent deposits. The dilution available, however, may require further treatment. To-day, screening is available where the areas tributary are relatively small and the sewage fresh, and in case screening be not sufficient, various styles of sedimentation tanks, either of the single or double-deck type, can be used to advantage.

It is difficult to state any hard-and-fast criterion that will cover all cases. The amount of dilution affords one key. Mr. Pearse suggests that where a stream is large and the dilution great, so that oxygen is always present to a high degree except in the vicinity of the sludge banks, dredging may prove an appropriate remedy. This is particularly true when the velocities of flow are sufficiently high to keep the settling material moving at other points.

Comparison on the basis of the cost per cubic yard of dredging and of sludge collected in tanks, is difficult. Roughly speaking, per cubic yard of material handled, dredging has the lower cost price. The total annual cost per cubic yard of sludge collected in a sedimentation plant, with Emscher tanks, would be considerably higher. The effectiveness and scope for application of sedimentation plants is, however, quite distinct from that of dredging.

The conclusions are: (1) Sludge deposits may form when velocities of flow are low. (2) The effect of sludge deposits is governed somewhat by dilution; nuisance may exist, locally, even though dilution be very great. (3) Sludge deposits will use up oxygen from the supernatant liquid. (4) Three remedies are available: dredging, by-passing the locality, and the removal of suspended matter before discharge. (5) Dredging is efficient as a cleaning-up process; it is not a permanent remedy, in that it may not reach all material, and is executed at infrequent intervals. (6) By-passing the locality is a temporary expedient, which may relieve present conditions and perhaps cause trouble later elsewhere. (7) The removal of suspended matter by screening or sedimentation is effective, and of permanent service. (8) Screening will remove the coarser material, the results depending very largely on the character of the sewage. (9) Sedimentation will remove practically all the settling suspended matter. (10) Effectiveness and cost must be balanced against physical conditions.

STREET ENCROACHMENTS IN TORONTO.

The question of street encroachments was the subject of a report by Mr. T. D. LeMay, O.L.S., [illegible] of the city of Toronto, to the City Council. The [illegible] report is as follows:—

The problem of reducing street encroachments [illegible] and failure to insert [illegible] [illegible] [illegible] Ontario Land Surveyor. [illegible] and boundaries, [illegible] The general question of taking such steps [illegible] would be [illegible] the appointment of an official whose duties would be the definition of all street lines [illegible] buildings, and the [illegible] encroachments [illegible] [illegible] information at present in this office being of such a meagre nature, would involve unlimited access to the field notes accumulated by the old established land surveyors of the city, which are, of course, their private property, and which they would not be prepared to throw open to the inspection of such an official, whose duties must very appreciably interfere with their practice, especially in the case of the older portions of the city, where the side lines of the lots are to a certain extent defined by possessory boundaries, and where the location of the street line constitutes for the purpose of the builder the whole survey. It might, of course, be possible to arrange some fee to be paid for each copy of notes taken, amounting to from $5 to $20 each, which, estimating the number of permits for 1912 at 8,000, would amount to a very considerable sum in the course of a year, even if the city were only called on to take action in, say, one-third of that number; and further, estimating at the rate of ten surveys a week for each such specially appointed official, it would be necessary to employ about six fully qualified land surveyors and a similar number of assistants, with an aggregate expenditure for salaries of about $14,000 per annum. The cost in this case appears to me to be prohibitive, and after careful consideration I would strongly recommend as an alternative that a by-law be passed enacting that every person applying for a permit to erect a building, any portion of which is designed to be at a less distance that two feet from the street line, or a building on any street upon which the building line is fixed by by-law, shall be required to hand to the City Architect simultaneously with his application, a plan of survey, made by an Ontario Land Surveyor, showing clearly the street line with reference to the kerb or some other permanent offset point. These plans to be forwarded to this office, where they could be placed on record with other information of a like nature. It would then be the duty of a specially appointed permanent official, being a duly authorized Land Surveyor attached to this office and working under my supervision, to check by means of the information given on the surveyors' plans the position of such buildings with regard to the street line or building line. A further duty of such an official would be to look out for and make careful enquiry into any apparent existing encroachment, and generally to compile such information in the way of ties to existing monuments as would tend to place this office more in a position of being able to dispense with the very valuable assistance that we obtain as a matter of courtesy from other surveyors in the city. In conclusion, I cannot too strongly suggest that immediate action be taken to do away with the property encroachments on public highways that are already of [illegible] to allow for the volume of traffic that they must carry.

◆

AMERICAN SULPHURIC ACID INDUSTRY.

It is estimated that some 200,000 tons of sulphuric acid are used annually in the iron and steel and coke industry in the United States out of a total consumption of [illegible] tons. The iron and steel industry, indeed, uses such quantities that a tendency is developing for steel companies to erect and operate their own sulphuric acid plants. A coke plant consuming [illegible] tons of coal per day would produce from [illegible] to [illegible] tons of sulphate of ammonia daily, according to the nitrogen content of the coal used. Therefore each [illegible] tons of coal high in nitrogen converted into coke daily, would call for a production of 10,000 tons of [illegible] deg. Bé. sulphuric acid per year. By-product coke ovens are now projected which will require 100,000 to [illegible] tons of [illegible] deg. Bé. sulphuric acid per annum in addition to the figure shown above.

PROTECTION OF CANAL LOCK GATES.

The protection of canal lock gates from possible injury from vessels is most important. Injury to the gates always means delay of less or greater length of time, and delay during navigation season on important traffic routes is most serious. Conditions demand the utmost facility in passing vessels through the canal during the open season.

An accident on the Welland Canal last week makes a total of five to date this season. This accident, which is noted in another column of this week's issue, is very similar to the others which have occurred this season. It caused a delay of some forty-eight hours in the operation of the canal, at the close of the season, when it is most important that the route should be open. The necessity for more adequate protection for the lock gates is very apparent. The Gowan safety device, which was described in a recent issue of *The Canadian Engineer*, has been very successful on the Welland Canal as a protection for vessels striking the gates lightly and forcing them open. This device consists of four very strong cast-steel fingers, two on each leaf of the gate, one towards the top and the other towards the bottom. These fingers project a couple of feet beyond the miter, so that one leaf can be pushed back very nearly the full length of the finger, but still give support to the opposite leaf. As vessels rarely hit the gates with great speed, this device prevents a number of accidents which would otherwise occur.

The number of serious accidents which have occurred this year, however, demonstrates the fact that a more efficient means of protection must be used.

The Panama Canal gates are protected by chain fenders. The function of these fenders is to prevent the lock gates from being rammed by a ship that may approach too near the gates under its own steam, or by escaping from the towing locomotives. In operation the chain is stretched across the lock chamber from the top of the opposing wall; when it is desired to allow a ship to pass the chain is lowered into a groove made for the purpose in the lock floor, and is raised again after the ship has passed. A hydraulically operated system of cylinders holds the ends of the chain. If a vessel should run into the fender, the chain is paid out gradually by an automatic release until the vessel comes to a stop.

It is time that the lock gates of the Welland Canal were equipped with some such protection as this. The capital cost of installing such devices is insignificant as compared with the resulting damage and delay due to these constantly recurring accidents.

◆

ACCIDENTS AND SAFETY PRECAUTIONS.

This week a railroad collision in Ontario accounted for several deaths and a large number of injuries. A prominent citizen in an automobile on his way to the station to meet the hospital train, was sufficiently hurt in a street car collision to prevent him from proceeding on his errand of mercy. These two incidents are passing from memory with the usual few days' wonder, indignation and sympathy. Within a week or so the stories will be buried in official records and newspaper files. Leaving them out of consideration, for the moment, they are still a grim reminder of the toll this country is paying for its craze for speed, its disrespect for human life. Every day brings its tragedies which might have been averted were the desire for haste reduced and the respect for the individual life increased. Is the price we pay for our much-vaunted hustle worth the hustle and the dregs we get? Here is the account in part for the three latest years:—

Three years, 1909-1911.	Killed.	Injured.
Fires	792	.....
Industrial	2,729	5,873
Steam railroad	1,407	4,751
Electric railroad	295	7,347
	5,253	17,971

No official record has been kept of persons injured in fires, but the number is large. The above figures, compiled from official sources, show that fires, industrial and railroad accidents have killed five persons and injured sixteen persons every day during the past three years. That is the total, in cold facts, of the quickly forgotten daily incidents. In addition to lives lost in fires, the annual fire waste in Canada amounts to an average of $20,000,000. These losses of life and property are shown, by careful analyses, to be caused largely by carelessness, caused in turn by an insane desire for speed. Adequate fire resistance is sacrificed for the sake of speculative building, which has become almost synonymous with the erection of poor quality in the quickest time for the most money. Our building by-laws are generally lax. Loose matches are an everyday danger. On every hand, one sees carelessness with fire risks.

Sometime ago, the subject of industrial accidents was discussed in parliament. Mr. H. H. Miller submitted a resolution, stating it to be the duty of the government to make a thorough investigation as to the facts and conditions as a result of which some means might be devised for the better protection of employees and of preventing so great a loss of life and so great and frequent accidental injury. The Minister of Labor at that time made the following statement: "We can say with certainty at this moment that a year hence another 2,000 lives will be swept off the list of workers in Canada, and in another two years there will be 20,000, whose industrial efficiency will be permanently impaired as a consequence of the callings in which they are engaged."

Our railroad accidents constitute the worst feature of the price we pay for hustle. Since 1888 to the end of 1911 7,728 persons have been killed on Canadian railroads and 27,574 persons injured, an annual average of 322 killed and 1,149 injured. Here, again, we can find the same basic cause, viz., the delusive craze for speed. Delayed trains are forced to make up time with disastrous results. Hazardous risks are taken by those responsible for operation with the lives of hundreds at stake. Taking chances is the curse of American railroading. Carelessness, which usually is the direct result of speed ambition, in some shape or form, accounts for a large number of accidents. Last year, for instance, [illegible] persons were killed and [illegible] injured by trains at highway crossings. An improvement was seen in the number of protective crossings [illegible] increased by [illegible] over the preceding year. There is probably in that fact a direct connection with the reduced number of accidents at highway intersections during 1911. These crossings are usually protected by gates, overhead bridges, subways, bells and watchmen. The last two have been proved by experience to be of little value. Gates, which usually consist of some bars under which pedestrians can climb and under which [illegible] can pass, are practically useless in that form. The present style should be abolished and one substituted which [illegible] should be non-negotiable by any kind of traffic. Overhead bridges and subways are by far the best form of protection.

A tendency was shown during the recent parliamentary discussion respecting industrial accidents, for the Minister of Labor to place the responsibility upon the industries concerned. That is a right view only after parliament has enacted stringent laws, and, more important still, has seen that they are enforced. The standard of public safety to which we are supposed to adhere is too low. It must be raised by our legislators and we must act up to it. After that, workmen's compensation is largely a matter for the railroad or other industry involved in lengthening the list of killed and injured.

These figures do not make good advertising for Canada, but idle boasting of our progress without self-examination of our weaknesses ultimately will only work to our own disadvantage. The public are demanding speed. They are being given it. The price paid is shattered nerves, human life and limb. In the meantime, legislators remain idle in face of duty.

◆

EDITORIAL COMMENT.

In an editorial on "Sanitary Engineers Needed," one of the daily papers of Ottawa states: "The people are coming to realize the reason for the unsatisfactory results obtained from the public health service in charge of medical doctors. They are beginning to see that the public health to be adequately protected must be looked after by sanitary engineers, rather than by general medical practitioners. There are still some, however, who hold the opinion that a Federal department of public health would correct the shortcomings of the existing provincial and municipal health departments. This proposal, however, as at present outlined, could only result in increasing the number of general medical practitioners in the public health service, and the chief cause for the unsatisfactory results would thus be left untouched, if, indeed, not increased." We are glad to note that the public are beginning to appreciate the difference between the practical methods of the engineer and the visionary schemes of many of the medical profession.

LETTER TO THE EDITOR.

Sir,—The following is a simple method for determining voids in sand. I don't know whether this has been used before, but if you have no record of it, I would be glad to have you publish it. I would also like to have the opinions of the various engineers upon this method.

For convenience use a glass cylinder graduated to [illegible] c.c. Fill with water up to the 100 c.c. mark and then pour in [illegible] of sand. There will be no necessity of measuring the sand before hand, as the cylinder containing the water will [illegible] measure the sand. When the [illegible] c.c. mark is reached, the water will have risen a certain amount; subtracting this reading from [illegible] will give the percentage of voids in sand, without any weighing.

This is obvious, due to the fact that there were [illegible] c.c. of water to start with, and if there are, say, 62 c.c. of water above the sand, there must be [illegible] c.c. filling of voids in the sand, and as there are [illegible] c.c. of sand, the percentage of voids would, therefore, be [illegible]. Taken another way, the [illegible] reading in this case would be [illegible] c.c., which, subtracted from [illegible], would equal [illegible].

E. S. BRUNER,
Manager of Publicity,
Canada Cement Company, Limited.

BIG BEND WATER POWER DEVELOPMENT OF THE FEATHER RIVER IN CALIFORNIA.

One of the largest hydro-electric power developments in the West has been partially completed by the Great Western Power Company, of San Francisco, Cal. The development is on the North Fork of the Feather River, a branch of the Sacramento River, which rises in the Sierra Nevada Mountains in the Northeastern part of California. The power house is at Big Bend, 18 miles above Oroville, and 160 miles from San Francisco, where most of the power is used.

At Big Bend, as the name would indicate, the river makes a long detour of a horseshoe shape; the distance around the bend is about 11 miles, but the distance across the neck of land is only 3 miles. The natural fall in the river in this distance is 413 ft. By means of a dam at the upper end of the bend the flow of the river is diverted into a pressure tunnel 3 miles long, across the neck of land, to the power house at the lower end of the bend where the total fall in this length of the river can be obtained. Here there are at present 4 units installed, each of 15,000 horse-power or 60,000 horse-power in all. The station is only one-half the size to which it will ultimately be built, but the tunnel is large enough for 4 more units.

In a paper before the Brooklyn Engineers' Club Mr. H. P. Rust describes the Big Bend power development in detail. An abstract of the paper follows:

Big Bend Development.—The development consists of a concrete diverting dam 40 ft. high, which will finally be raised to 130 ft. in height above the original water level. This dam turns the flow through a concrete lined pressure tunnel three miles long. Part of this tunnel is an old mining tunnel, formerly used to drain the river bed around the bend, which has been enlarged and lined. At the outlet there is a riveted steel header pipe securely concreted into the end of the tunnel. This branches into four smaller penstocks down the side of the canyon and connects with each of the four turbines in the power house below. The end of the harder pipe is turned up the hillside to a level 35 ft. higher than the crest of the dam and forms a surge pipe, or vent, and prevents any excessive pressure of water hammer in the tunnel due to quick closure of the turbine gates. The problem of the development was a peculiar one and there are several conditions which make it unlike any other in the West. First, there was the old mining tunnel which had to be used. This had a steep grade and a fall of 70 ft., too much to be wasted by using a gravity tunnel, so this necessitated a pressure tunnel. A new tunnel or extension was necessary from the exit of the old one in Dark Canyon to the main river, 3,400 ft. long, to obtain all the head available with the shortest possible head-race. With a pressure tunnel and pipe lines, all enclosed, the quantity of water flowing could be quickly changed, thus allowing for changes in the load on the generator without having to waste water over spillways, as would be necessary with a gravity conduit, in which the flow would have to be constant nearly all the time.

The pressure tunnel allowed the use of a high dam at the intake to increase the head and to form a balancing reservoir to carry daily peak loads or store water over Sunday. With such a reservoir no water need be wasted on account of any load factor which may be obtained for the plant, and the average flow during the day could be stored when the load was light and used when the demand for power was at its greatest. By means of the reservoir and pressure tunnel the amount of water which could be obtained from the low flow in the river is increased from 50 to 60 per cent.

The chief disadvantage of a pressure tunnel in such a case is the difficulty of taking care of the water hammer and providing for close regulation, but by special precautions afterwards described this may be safely taken care of. This design necessitated engineering and construction work of a high character, much more so than is customary with most power plants in the West.

In order to get the plant started as soon as possible and cheapen the first cost, only half the power was first built and the high dam has been deferred. But the tunnel has been made large enough and all connections provided so that the power house may be doubled and four more units installed without interfering with the operation of the first installation.

Construction Plant and Camps.—The main problem before the railroad was completed, as far as the work, was transportation. This had been promised for early in the summer of the first year's work, but the railroad engineers also had their trouble and it was not in operation as far as the power house until the following spring. During this time all supplies and plant had to be hauled 20 miles from Oroville. About 25 miles of new roads were built into the different camps and the saw mills.

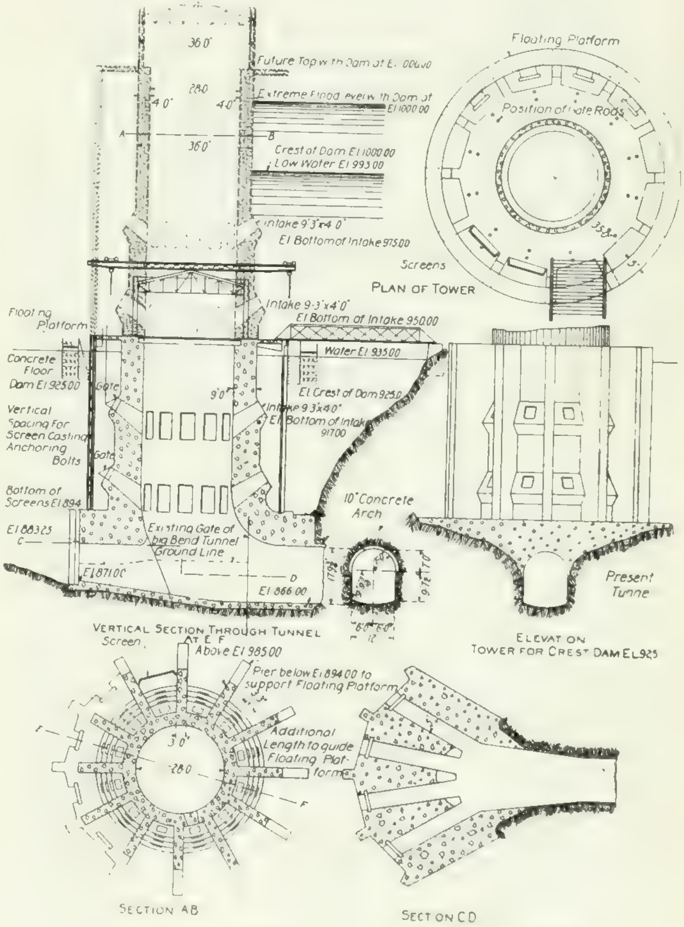

Fig. 1.—Details of Tunnel Intake Tower.

Work was started in the fall of 1906, and the weather during the first winter was very bad. There was a great deal of rain and snow and the roads were almost impassable. However, sufficient plant, boilers, compressors and supplies had to be hauled in to start the tunnel excavation. At the intake there was a camp (Camp No. 7) accommodating about 300 men. Besides the concrete plant here, there was a 1,250-cu. ft. steam-driven compressor and boilers, etc.

The principal camp (Camp No. 3) was in Dark Canyon, at the exit of the old tunnel. Here there were accommodations for about 600 men and the principal repair shops, etc. The camp at south portal above the power house (Camp No. 4), had accommodations for about 300 men. Besides these, there were two saw mills, Camp No. 6, and Camp No. 8, each with a capacity of 10,000 ft. of lumber per day; and also the headquarters, Camp No. 1, and the various storehouses, commissaries, etc.

As the work was carried on shortly after the San Francisco fire, labor was very scarce and of poor quality. The maximum force was about 1,600 men and it averaged 1,200 most of the time. No contractor could be found who would undertake the work at a reasonable price, as all who were asked to bid seemed afraid of the inaccessibility of the site, so all the work at Big Bend was carried on by the engineers by day labor. Among other troubles, there were two severe floods, the first of which washed away most of the buildings in the headquarters camp, and one bad forest fire which burned over a large portion of the company's property at Big Bend and endangered the camps and equipment.

Intake Tower.—In order to control the water entering the tunnel at all levels at which the water might stand in the reservoir, and also to provide access to the tunnel from this end, a concrete gate tower has been constructed. It is of somewhat unusual construction (Fig. 1) and is a massive piece of work. It consists of a heavy hollow concrete cylinder 28 ft. in inside diameter, with walls from 12 to 7 ft. thick; it is now finished to 76 ft. high, but, when the high dam is built, will be 163 ft. high.

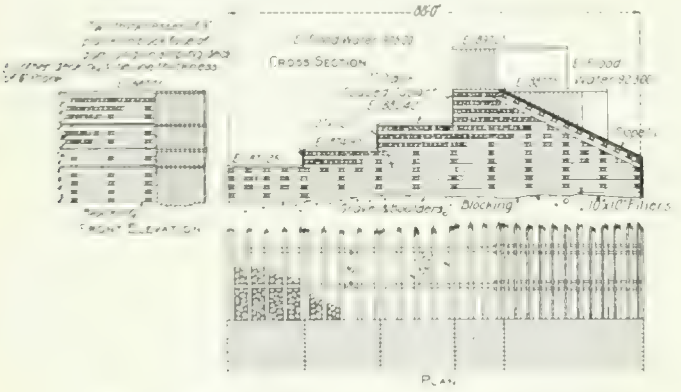

Fig. 2.—Details of Temporary Timber Dam.

Around the outside there are 12 buttresses 3 ft. thick, between which there are now 2 tiers, but ultimately 4 tiers of 12 flap gates, making in all 24 gates now in use, and ultimately there will be 48. They are each 3 ft. 4 ins. x 4 ft. in the clear and are made of steel plate. The frames, however, are cast iron. The gates can be opened by the rod extending up to the floor, which is lifted by a hand-operated crane. Their principal advantage is that they can be closed so easily; by simply releasing the rod at the top, they close of their own accord, so that in case of accident all the gates can be closed very quickly and it does not require any power. In opening them one of the upper gates, which does not require much power, is first opened, allowing the tunnel to fill gradually and equalize the pressure on each side, so that the lower ones can then be easily opened.

Outside the gates and between the buttresses are the racks. These are made up of [illegible] flats, spaced [illegible] apart, and [illegible] girders bolted to the side of the buttresses. They are arranged to be raked from a floating platform moving between the buttresses.

This arrangement allows water to be taken from nearer the surface and insures freedom from sand, silt or debris. It [illegible] with a minimum of [illegible]

In order to start the plant before the dam was finished, [illegible] temporary openings were left through the bottom of the tower. These were controlled temporarily by steel and red-wood gates, [illegible] But since the completion of the dam they have been closed permanently and will not be used in the future.

During construction of the tower, access to the tunnel had to be allowed for as it was being excavated and lined at the same time. A crushing and concrete mixing plant was erected near the tower and concrete was mixed here for both the tower and for lining this end of the tunnel. A quarry of hard trap rock was opened up just upstream. There was also a compressor located here of 1,250 cu. ft. per min. capacity to supply compressed air to this end of the tunnel.

No sand for concrete could be obtained nearby, so 2 sets of 24-in. crushing rolls were installed in the crushing plant to crush rock fine enough for use as sand.

There was not room for a camp and quarters near the river, so this was located about 350 ft. higher up the canyon side, above the tower, with accommodations for about 300 men.

Timber Dam.—In order not to interfere with work in the tunnel and protect this end of it from a higher water level, the intake tower had to be practically finished before the diverting dam could be started. Work on the tower could not be rushed without interfering with work in the tunnel, so that it required all the first working year to complete the tower and the dam could not be started until the second summer.

In order to get the plant started as soon as possible, this left only one season in which to build a dam and it would have been impossible to put in the foundations and build a masonry dam in one summer, only about six months. So it was decided to build a temporary timber dam (Fig. 2) sufficiently high to turn the water through the lower sluiceways of the intake tower and build the masonry dam later.

The timber dam was located just above the site for the masonry dam, and built so it would later act as a cofferdam for the masonry dam. It is about 700 ft. downstream from the intake tower. Also, as the Western Pacific R. R. was not finished as far as the intake, the cost of cement and sand would at that time have been excessive for the construction of any large amount of masonry. The timber dam is shown in plan and cross-section. It has a slope of 2 in 1 on the upstream side, a level crest 10½ ft. wide, and three steps on the downstream side, each 16 ft. wide. It was arranged so 8 ft. of flash-boards could be added on the crest. The crest is 22 ft. above the tunnel invert at the intake. It is about 18 ft. above the original water, or about 26 ft. above the river bottom, and is about 280 ft. long. The dam is built of 12-in. x 12-in. square timbers bolted together with ⅞-in. drift bolts 26 ins. long. Additional longitudinals and rakers are spaced 4 ft. apart to support the deck. This is made of two layers of 3-in. plank on the upstream face and of one layer of 6-in. plank on the crest and the downstream face.

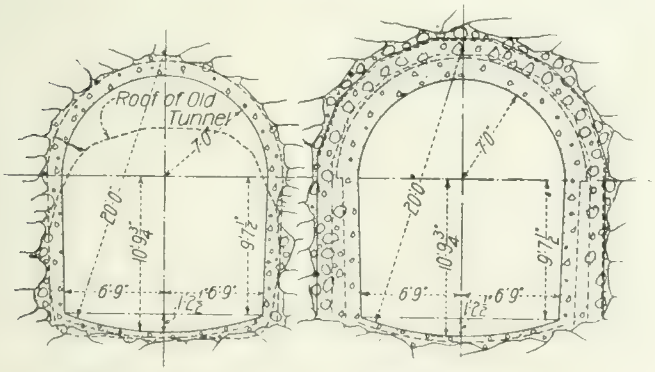
The dam was built in the dry between two cofferdams. It is founded on solid rock, at each end, but in the centre of the river rests on the boulders and hard pan of the river bottom. A row of timber sheet piling was driven along the upstream face to prevent leakage under the dam. During the first winter it successfully withstood a flood of 95,000 sec. ft., about three-fourths the maximum expected in the river. This overtopped the crest about 22 ft. No leaks developed, except one at the end, through a crevice in the rock, and the pond above was filled with so much silt it made the dam quite tight. However, the large amount of silt in the water caused a sand blast action, which wore away the decking in some places from 2 ins. to 4 ins. The timber for the dam was all obtained from the company's property near Camp 8, on the east side of the Bend, and was sawn at the mill there. It is mostly pine.

Permanent Dam.—The masonry dam was not started for a year after the timber dam was finished, and has just been finished up to El. [illegible]. It is about [illegible] ft. long on the crest and is [illegible] ft. high above the river. It is high enough to turn the water through the gates of the intake tower and to form a regulating reservoir to store water for the daily peak loads and enable the station to operate at any load factor without wasting water. It has a gravity Ogee section of cyclopean concrete masonry, and is very broad at the base on account of the severe floods. The maximum flood will overtop the crest about 23 ft. The foundation is a very hard and tough diorite rock, locally called greenstone. The bottom of the river was covered with large boulders and gravel, which had to be excavated. The lowest point of the foundation is 45 ft. below the original water level. In constructing the dam a new camp and quarters were built. Four Lidgerwood cableways were used and a large new rock crusher plant and concrete mixing plant installed. Of course, it is intended, as explained before, that this dam will ultimately be built 90 ft. higher.

Tunnels.—As was shown on the map, the old tunnel of the Big Bend Mining Co. only discharged into Dark Canyon, and did not go completely across the neck of land to to the main river below. This old tunnel has quite an interesting history. It was started in 1883 at the time placer gold mining was booming in that part of California, the idea being to divert all the dry season flow of the river through the tunnel of 12,300 ft. long to Dark Canyon, and leave the river around the bend dry, thus allowing the company during the summer to work the gravels and sand in the river bed and extract the gold which was supposed to be there.

The tunnel was started from the Dark Canyon end, and required three years to complete. It was about 8 ft. high by 13 ft. wide, and had a grade of 5 per 1,000. The progress was rapid, 400 ft. being made one month. A timber diverting dam was built across the river just below the intake, but when the water was turned through the tunnel it was found that unfortunately the tunnel had not been made large enough, and would not take nearly all the summer flow. It was then enlarged, requiring another year, by taking 4 ft. more from the roof of the tunnel, making it 12 ft. x 13 ft. in cross-section. The cost of the complete tunnel was then $750,000.

Work was started prospecting the river in 1888, but with poor success. The next year the company spent $100,000 to obtain about $40,000 worth of gold, hardly a paying proposition, so the project was abandoned. The tunnel then lay idle until purchased by the Great Western Power Company to be used as part of their development.



CROSS SECTION IN SOLID ROCK TIMBERED SECTION

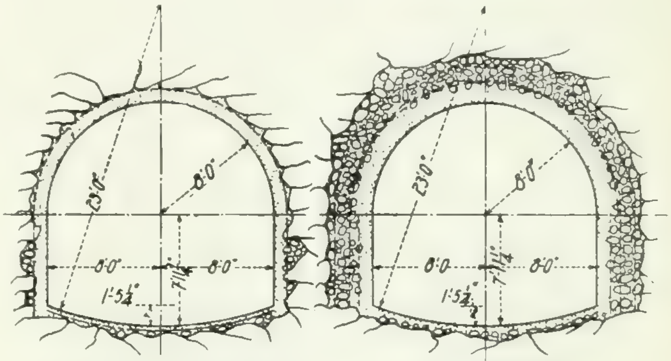
Fig. 3.—Typical Sections of Enlarged Tunnel.

The maximum flow required in the tunnels is 2,500 sec. ft. The maximum allowable velocity decided on was 11 ft. per second, so the net cross-section was made 220 sq. ft. inside the concrete lining. The old tunnel measured about 12 ft. x 13 ft., so it had to be considerably enlarged. It was made of a horseshoe section 18 ft. high x 14 ft. wide inside the lining, or 20 ft. by 16 ft. outside the lining, Fig. 3. The enlargement was made by taking from 5 to 6 ft. from the roof and by trimming 2 to 4 ft. from one side. This is the reason for making the section so high in comparison with its width, as it was considered more economically in making the enlargement to take as much from the roof as possible.

The 3,400 ft. extension, or new tunnel, being entirely new, could be made a better section. As shown, Fig. 4, it is 16 ft. wide x 16 ft. high inside the lining, horseshoe shape, but the same net area.

The concrete lining is intended to be 12 ins. thick. The minimum allowed on the sides and arch was 6 ins., and 4 ins. on the invert. From careful cross-section taken with a sunflower the actual thickness averaged 21 inches.

At the intake the invert is 54 ft. below the present crest of the dam; throughout the new tunnel and in the header pipe about 120 ft. below. When the dam is raised to its final height, the header pipe will be 200 ft. below, and the tunnel has to withstand the internal pressure due to this.



CROSS SECTION IN SOLID ROCK TIMBERED SECTION

Fig. 4.—Typical Sections of New Tunnel.

The ground is solid rock throughout. The new tunnel and both ends of the old tunnel are through shale, but about 6,000 ft. in the middle of the old tunnel is through a very hard and tough blue trap, really a diorite.

The surface of the ground is mostly from 400 to 1,500 ft. above the tunnel and all rock. The few springs encountered in the tunnel or appearing along the canyon side, tended to show that the ground water level was much higher than that necessary to counteract the internal pressure in the tunnel. On this account weepers (2-in. diam. pipe) were placed in the lining to relieve any pressure from the outside, one for each 100 sq. ft. of lining, and extra ones where any springs were encountered. However, the tunnel was very dry, and none were struck which gave more than what a 1-in. pipe would carry.

There were, however, three exceptions where all weepers were omitted and the lining was made at least 24 ins. thick. First, for about 200 ft. in from the intake. Second, for about 400 ft., where the new tunnel branched off from the old and ran under Dark Canyon. At one point here there is only 80 ft. of rock overlaying the tunnel. Third, for about 373 ft. in from the header pipe or to a point 500 ft. away from the portal above the power house. Great care was taken at these places to secure dense concrete closely packed against the rock.

In the other parts of the tunnel the rock is depended on to take the pressures, and the lining is considered merely as a means to obtain a smooth tube with small hydraulic losses. In fact, one engineer seriously proposed lining the tunnel with planed red-wood timbers supported on concrete cradles.

The proportions of the concrete mix were 1:3:5. Pudding stones were embedded in the concrete where possible, keeping them 6 ins. from the face. Very little timbering was necessary except at each portal. At the intake end and throughout the tunnel the timbering was all left in place; but at the portal above the power house it was removed, before the lining was placed.

The exit into Dark Canyon was closed by a concrete bulkhead 25 ft. thick. Two 12-in. pipes fitted with gate valves were left through this to drain the tunnel and act as sand traps.

The excavation from the roof of the old tunnel was carried on from heavy traveling timber platforms 24 ft. long. The rock was blasted directly onto these, then mucked into the cars below, and hauled away by electric locomotives. There were generally three platforms for each gang of miners drilling being done on one, while mucking from a second and moving the third ahead. Twenty travelers, or jumbos, were required in all, a number being broken in the hard trap rock. The progress varied according to the hardness of the rock, from 10 ft. per day to 3 ft. per day per gang of men.

The new tunnel was driven with a full width heading followed by a single lift bench. It was worked from both ends; that is, from Dark Canyon, and also from the power house end. The result was a maximum progress of 64 ft. a week in each heading.

The lining was not started until the excavation was nearly finished, as it was considered better to wait until the Western Pacific R.R. was running as far as the power house, so cement and sand could be obtained at a reasonable cost, by saving the wagon haul from Oroville. On this account it was necessary to rush the lining in every way possible when it did start.

The concrete was placed back of traveling forms operated in sets, made of timber. Each set consisted of an air hoist, 60 ft. of side wall forms and 60 ft. of arch forms.

These were arranged so the forms could be released as soon as the concrete had set and the carriage run ahead on rails to its new position. A 60-ft. form could be released, run ahead and set up again in from 3 to 6 hours by a small gang of men.

One gang operated two sets of these forms and would fill one while the concrete was setting behind the other. From four to five gangs, both day and night, were employed, and the record progress was the equivalent of 860 ft. of complete lining in one week.

The concrete was all mixed outside the tunnel and was hauled in by the electric locomotives.

There were three mixing plants, one at the intake, one above the power house and one in Dark Canyon. Each consisted of a No. 5 rock crusher and two ½-cu. yd. Smith mixers. There were two sets of 24-in. crushing rolls at the intake to crush rock fine for use as sand. Sand for the other plants was obtained from Marysville, 46 miles down the river on the Western Pacific R.R.

At Dark Canyon was located the principal camp and equipment. It was crowded and inconvenient, as there was practically no level ground on which to place anything. There were accommodations here for about [illegible] men. There were also an air compressor with a capacity of [illegible] cu. ft. per minute, eleven 50-horse-power boilers, machine shop, blacksmith shop and the concrete plant. Cord wood was used for fuel until most of that in the district was burned, and then crude oil was used. [illegible]

CARE OF BOILERS.

[illegible]

DRIVING A DOUBLE-TRACK TUNNEL IN JAPAN.

The Japanese people have given us many evidences of their progressiveness, but nothing emphasizes their spirit of progress more than the work which they are now doing in building a double track, wide-gauge electric railway, between Osaka and Nara. Mr. W. L. Saunders describes some of this work in a recent issue of the Mining and Engineering World, from which we have abstracted the following:

Osaka has been called the Pittsburg of Japan. It is the commercial metropolis, with 1,000,000 inhabitants, covering an area of more than 8 square miles, intersected from east to west by the river Yodo, and with numerous canals running through it, Osaka is admirably situated for a manufacturing city. Its principal trade is with China. On arriving at Osaka one is impressed by its industrial activities as illustrated by the large number of chimneys. Old Osaka has left its monument in the great castle built by Taiko Hideyoshi in 1583. Little remains of the old castle but the ruins, and principally the walls of the moat. These walls contain huge blocks of hard granite, some of them measuring 40 feet in length and 16 feet in height.

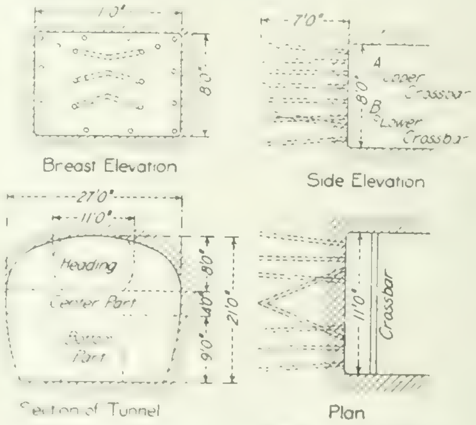

Fig. 1.—Scheme of Drilling Heading.

From Osaka to Nara is from new to old Japan, for Nara is in every respect representative of what Japan used to be. It was the ancient capital during seven reigns, and until the seat of government was removed to Kyoto. At Nara is the largest statue of Buddha, built in the year 746.

The railway now under construction is a short cut designed to reduce the time of travel and the mileage. The line runs through Mt. Ikoma, which is located about half way between Osaka and Nara.

The contract for the construction of this tunnel was awarded to Obayashi Gumi, the engineering work being in charge of Dr. Eng. T. Oka. The tunnel work begins in the eastern end at Ikoma village, extending westwardly to Hineichi village, a distance of about two miles.

The finished dimensions of the complete tunnel are [illegible] feet in width by [illegible] feet in height. Work was begun on July 3, 1911, and is now being prosecuted from the two ends.

Fig. 1 shows the methods pursued in this work. The upper pictures represent the heading, one being an elevation showing the breast, and the other representing a vertical section, or elevation, through the heading.

The lower sketch to the left in Fig. 1 shows a section across the tunnel, illustrating the entire width and height, and [illegible] the heading in the upper central part, with the centre pillar separating the heading and the bench, or bottom part.

To the right and to the left of the heading, and to the right and to the left of the bench, are sections which are excavated by the use of stoping drills. The centre prism is also removed in the same manner.

The plan immediately to the right of this section illustrates the cross-bar used for mounting the drills in the heading. The heading is 8 feet high and 11 feet wide; the centre part is 4 feet high and 27 feet wide, and the bottom part or bench is 9 feet high and 8 feet wide.

In the heading a bar 5 inches in diameter and 10 feet in length is fixed horizontally across the tunnel. Jack screws, located in each end of this bar, serve to adjust it to proper lengths, and to fix it rigidly against the walls. Three water Leyner drills are mounted on this bar, and the upper holes are first drilled. Then the bar is lowered to a point nearer to the bottom of the heading, and the lower holes are drilled.

Because of the use of these light-weight drills, which do not kick hard against their mounting, it is possible to employ this bar in place of the usual columns. Columns with arms are mainly used in America, because drills of the percussion type require a very rigid mounting. It is obvious that the use of the horizontal bar facilitates the handling of the drills, and makes it possible to set up after a blast quicker than by the use of columns. The whole thing with the drills mounted is handled readily by a gang of men, who climb up over the muck, placing the bars in position and drilling the holes, while the muckers are at work below them.

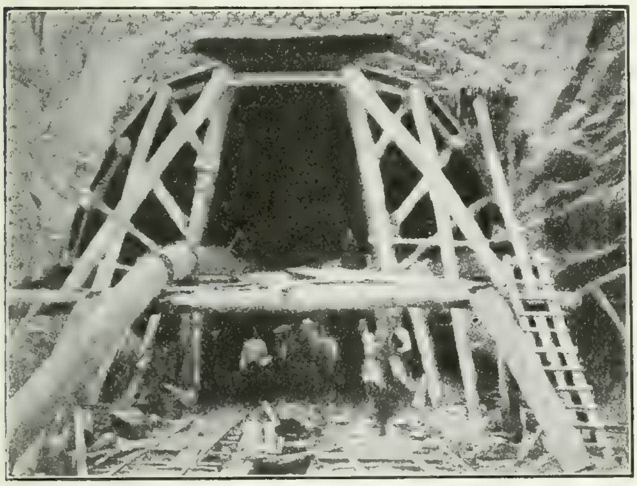

Fig. 2.—Tunnel Portal.

The centre, or cut holes, are drilled to a depth of 8 feet, all the other holes being 7 feet in depth. Blasting is done by time fuse, which is admitted nowadays to be the best practice. Gelatine is placed in the bottom of the hole next the primer, over it is placed some gelatine and then 60 per cent. dynamite. Clay is used for tamping. Where the rock is hard, from 22 to 26 holes are drilled in the heading, but in softer rock this number is reduced to 16 holes in some cases, and in others as low as 12 holes. The rock in Mt. Ikoma is granite, usually hard, especially in the east end.

Progress in this tunnel has averaged over 10 feet of heading per day. Records have been made of 20 feet in 24 hours, single heading This was on the west side where the rock is of moderate hardness. It usually requires 5 hours to drill 20 holes, 6 to 7 feet deep. The work of loading, firing and taking out the rock consumes about 3 hours, or a total shift of 8 hours. The work is done by the miners in 6-hour shifts, working day and night. One superintendent is in charge of each heading, with three drillers and three helpers.

Mine cars made of wood are used, carrying a capacity of 30 cubic feet, track 30-in. gauge, 25-lb. rail, the train of 10 cars being hauled by an electric locomotive.

For ventilation 50-h.p. Root blowers exhaust through a 20-in. stack. Ingersoll-Rand air compressors of 115-h.p. each furnish the compressed air at 100-lbs. pressure, the air being conducted to the heading through a 5-in. pipe.

The holes drilled are usually of about 2 ins. in diameter, and the progress of the drills is from 7 to 12 inches of hole per minute. Although water is fed into the bottom of the hole, the discharge of the cuttings is really effected by compressed air, which is forced in with the water, the minimum amount of water being used, and only for the purpose of laying the dust.

Power at the portals of the tunnel is transmitted electrically as a distance of 16 miles at 3,500 volts; 16-candle-power electric lamps are used for lighting.

Up to May 31, 1912, an advance was made in the east end of 2,127 feet, and in the west end 1,917 feet, or a total progress of 4,044 feet. The tunnel is to be lined with brick, about 1,000 feet being already completed.

WORKMEN'S COMPENSATION IN ONTARIO

In connection with the Royal Commission appointed by the Ontario Government to consider the question of compensation to injured workmen, the commissioner, Sir William Meredith, is visiting England and the continental countries to investigate on the ground the systems in operation in these countries.

A plan may be proposed by which all workmen sustaining personal injuries by accident, arising out of and in the course of their employment, will receive compensation, irrespective of who was to blame. A Workmen's Compensation Act of such a nature would be only similar to those adopted in the other Provinces throughout the Dominion, as well as in England.

There is a suggestion in the interim report of the Commissioner that the manufacturers of Ontario are favorable to a scheme of State insurance. The details are not disclosed, but the scheme would probably be operated on an assessment plan.

Commenting on this, Mr. Alex. MacLean, manager and secretary of the London and Lancashire Guarantee and Accident Company of Canada, says: "State insurance is a movement towards paternalism of government, more far-reaching than any economic measure heretofore proposed. The adoption of such a plan commits one to a principle, which, if carried to its logical conclusion, means that any or all commercial industries may properly be conducted by the government to the exclusion of private enterprises.

"It is for the government to decide as to what form of legislation to place on the statute books in respect to compensation to injured workmen. That is one thing, but for the government arbitrarily to fix the rates that the employer must pay for his protection is taking away the inalienable right to purchase insurance, or protection, at the lowest possible cost.

"Any legislation that will eliminate law costs and provide adequate compensation to the injured workmen will be gladly welcomed by the insurance companies. Let the government pass such an act, and if necessary see that the liability companies are subject to the closest government inspection so that no injustice will be done the employer in the fixing of rates. It will be found that there will be a better feeling between the employer and employee than if arbitrary rates are fixed by the government under a system of State insurance and injured employees are compelled to look directly to the government for compensation."

CANADIAN PACIFIC EAST-BOUND RATES AND EMPTY CAR MILEAGE

An official of the Canadian Pacific Railway, in speaking of the freight rate situation, high eastbound rates and general traffic conditions, says: "Nearly 40 per cent. of our freight trains moving westward are made up of empty cars, and it costs nearly as much to haul an empty car as it does to haul a loaded one. This empty movement is one of the largest shown by an important division of any great railroad company, and it practically means that the rates on eastbound tonnage, in order to protect the company, must be high enough to cover the eastbound haul, and also the expense of returning the empty cars to the Pacific coast.

"The bulk of this traffic," he says, "consists of lumber, and for this are used principally the ordinary box cars, which are suitable for the haulage of grain or general merchandise. It is only the long timber that is hauled on flat cars. If the cars which now return empty could be loaded with grain or merchandise, the cost of the westward trip would then fall on the latter and the burden removed from the eastbound traffic.

"In the United States, roads that show an empty car mileage of about 20 per cent. are considered expensive to operate, and in our traffic we have an empty car mileage of approximately 40 per cent." He also points out that the Canadian Pacific has probably invested more money in roadbed and equipment than any other road moving a high percentage of empty cars The line from Calgary to the coast has not yet become a profitable investment, but it was necessary to build the line in order to reach the large lumber sections and mineral deposits of British Columbia and to furnish an outlet for Canadian products to the Pacific coast.

On this division there is almost a total absence of local traffic, whereas it is on heavy local traffic that railroads principally depend for profits. The cost of road, he points out, is about $100,000 per mile, equipment included, through the Rocky Mountain section, and yet the traffic developed up to the present time is considerably less than on most roads costing not more than about $60,000.

Pacific coast extensions have proved a somewhat expensive necessity without an adequate return of profit, but it is in keeping with Canadian Pacific policy that this work is undertaken, for this road has always built far in advance of traffic demands. At present, Canadian Pacific is spending about $2,500,000 for a new station and office building at Vancouver, and also a new pier at Vancouver Island.

A large westbound traffic in wheat, which may be reasonably expected in time, will have the effect of lowering rates on eastbound freight and incidentally enable manufacturers to extend their markets in Alberta, Saskatchewan and other eastern provinces.

◆

THE UPPER ATHABASKA REGION.

The rapid linking together of the Grand Trunk Pacific [illegible] [illegible] [illegible] [illegible] central Canada [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] Central [illegible] [illegible] [illegible] [illegible] and of all this there is [illegible] [illegible] [illegible] [illegible] [illegible] region [illegible] [illegible] [illegible] [illegible] of the Athabaska River and [illegible] [illegible] [illegible]. The [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] of the [illegible] is Fitzhugh, a [illegible] [illegible] [illegible] Jasper Park, some two hundred and fifty miles west of Edmonton.

How little of this region has been actually trodden by white men is evidenced by the fact that only four short summers ago the largest sheet of water on the entire east slope of the Rockies was found in its recesses. This beautiful mountain lake, some seventeen miles in length, and lying between green wooded slopes, forms a broad expansion of the Maligne River, and resembles a Scotch tarn in its far-melting vistas of water and crag. This lake is some thirty miles south-east of Fitzhugh, and twenty miles farther south is another large lake, where the trout fishing is excellent. The latter body of water forms the chief source of the Brazeau River. To the west of it, in Alpine grandeur, lies the region of wild, lofty peaks, dominated by Mount Alberta, where enormous glaciers give birth to the Athabaska and North Saskatchewan Rivers.

This region is also a noted game country. It lies far enough north to have escaped in part, during recent years, the far-searching reach of the Stoney Indian; bears of all kinds are still fairly numerous; the sheep (and more especially the goat) hunting is good, while scattered moose, deer, and even elk, may be occasionally seen.

Meantime, the crying need of the district, for tourist and fire-ranger alike, is the need for more and better trails. Hence, to provide a good and adequate system of trails will be the first and constant effort of the Dominion Forestry Branch in carrying out its recently assumed duty of administering this region, so as to protect its forests from fire and make every auxiliary resource contribute its part to the public welfare. During the present season the rangers in charge made a good start on this work, and next year it will be again pushed with vigor. Already, between Laggan or Morley, on the Canadian Pacific Railway, and Fitzhugh, an old through trail is in existence, a trail which promises to be a very popular Alpine tourist route when improved. It traverses the Brazeau, Clearwater and Bow River, forests, and everywhere its improvement will be promptly undertaken by the Forestry Branch.

The scenery in this upper Athabaska country is varied and beautiful in its color effects, and specially so in early autumn. From the deep green carpet of pine and spruce on the valley floor the eye passes to intermingled belts of blushing gold poplar and light green lodgepole, fringed above to timber line by sombre masses of Alpine fir. Higher still, the warm reds and ochres of disintegrating ferruginous rocks form a Joseph's coat of many colors, while over all loom the background of summits wrapped in their eternal snows.

◆

THE AUSTRALIAN TRANSCONTINENTAL RAILWAY.

At Port Augusta, South Australia, on September 14th, the interesting historic ceremony of breaking the first sod in the construction of the Transcontinental Railway was performed by the Governor-General (Lord Denman). A large number of legislators and others interested in the work were present. This new line, to connect the State railway systems of South and Western Australia, will be [illegible] miles in length, and the gauge is the standard of 4 feet 8½ inches. The highest point on the line is an elevation of [illegible] feet and the steepest gradient 1 in 80. It is estimated that the work will be finished in from three to four years at a cost to the Commonwealth of, approximately, [illegible].

The completion of the railway will open direct communication (independent of the existing steamer service from Adelaide, S.A., to Fremantle, W.A.) from the eastern states with Western Australia, which is the largest state in the federation, comprising an area of [illegible] square miles, with the present limited population of about [illegible]

LIGHT COMPRESSION MEMBERS.

On March 11th, 1912, the Western Society of Engineers held a meeting at which a topical discussion of the design of light compression members was taken. The discussion is given herewith:

Horace E. Horton: I have just one thing to urge in connection with the details of compression members—not necessarily light members, but all members. The error I discover is that the principal part of our discussion turns on the radii length, while it has developed, with the built-up members universally used, that the composition of the section has more to do with its efficiency than its radii length.

Our knowledge of column design has been evolved from laboratory experiments on solid rounds and small pipe, made approximately eighty years ago. The laws of flexure for rolled sections were fairly well developed by these early tests; in fact, we have repeated examples justifying the laws of flexure as set forth in the formulae. In the evolution of things, however, we have come to build compression members that are not rolled but are composite structures, usually of plates and angles. We may use channels or we may use beams, but practically speaking, the members are built up of plates and angles. There are specifications in general use that allow a greater compressive than tensile stress per unit section of the same material. It was this error that culminated in the Quebec disaster. Compression members of forty radii were used with as great a unit stress as that allowed for tension, and in some cases a still higher unit stress was allowed on these compression members. As a matter of fact, the compression members of that structure failed with one-quarter the unit load that the material would have sustained in tension. Now, it failed how? Not by flexure, but by the wrinkling of the component elements.

Another engineering society started, some years ago, to gather all available statistics with reference to compression members. The committee of that society concluded that laboratory tests were of no value and they found, altogether, 268 recorded tests of large compression members, 184 of which were of iron and almost obsolete, except as illustrating general laws. A second group of 52 tests were made on rolled sections, namely, pipe and **H** sections. The tests of this second group undoubtedly show the maximum efficiency possible in a compression member. Each one of a third group of 32 built-up members failed by wrinkling of the parts. Not one of them yielded by flexure. In other words, none of the tests of which we have record shows a built-up member which was so designed as to reach its maximum efficiency.

We are left with the question: Suppose two, or three, or four times as many rivets had been driven through the angles and plates; or again, suppose that rivets of twice the area had been used. Would the members have sustained a greater load? Would we have obtained a greater efficiency from the material by using more or larger rivets?

What we want instead of 32 is more than 1,000 tests, varying the constituent elements such as radii length, size, and number of rivets. It happens that the members of this third group of built-up members represent about 65% efficiency, as compared with the rolled sections, at their point of failure. The loss is 35%, and it is here that experimental research can point the way to better design. We will have to have a large number of tests to give us the knowledge necessary to design to the best advantage.

Because the cost of a sufficient number of tests of full-sized members is prohibitive, I am personally inclined to think that laboratory tests are all that we can hope to get in sufficient number. Suppose we use a built-up section of two plates, 4 by ⅛ in., four angles ¾ by ¾ by ⅛ in., varying the size of the lacing and the size and number of rivets as the research advances. This section would have a gross weight of, say, 8 lb. per lineal ft., would have a radius of gyration of 1.5 and a sectional area of 1.42 sq. in. The length for 24 $\frac{l}{r}$ would be 3 ft., and for 240 $\frac{l}{r}$, would be 30 ft.

If we should make tests of five members of each of these lengths and eight intermediate lengths, we should have 100 tests which would undoubtedly point out many valuable facts. By making 1,000 tests in all, it would probably be possible to discover the spacing and size of rivets to make the material fail by flexure rather than by wrinkling.

The Pennsylvania Lines (Panhandle) not long ago made elaborate tests of six large members about 40 ft. long, each nearly 100 sq. in. in cross section. The material for these tests alone represented some 80,000 lb., or about the equivalent of the material required for the 1,000 tests suggested above.

I believe that we are safe in concluding that there is no mere mental analysis that will ever show us the required relations. Physical tests are required. We have only 32 tests of full-sized steel members in all the years that have gone. These members were all designed on the theory that they would fail by flexure. They all did fail by wrinkling. Failure by wrinkling invariably indicates a low efficiency and a poorly designed member. Sections such as I have indicated can readily be handled in our university testing machines. At the University of Illinois, as at other engineering colleges, there are ambitious professors and active students. Give them a chance. I believe that if this society would become interested in the subject, it would be possible to actually devise means whereby 1,000 such laboratory tests could be made, thereby adding more to our knowledge of the compression member than we could hope to obtain in any other way.

F. E. Davidson: In this discussion I trust some one will take up the question of a rather long compression strut with light loading, and show us how he would build an economical strut out of ordinary stock sections. That is a problem that architects and engineers have to meet constantly. The requirements of our revised building code with regard to compression members are very rigid compared to what could be done a few years ago. There are certain credits given to steel that is encased in concrete under certain conditions; that is, one can use a higher stress in certain types of columns than in other steel shapes with the same amount of concrete fireproofing.

When I was with the Illinois Steel Company I often used, in struts between roof trusses, a light channel with a plate riveted to one flange. For instance, with a 7-in. channel I would use a 7-in. plate and run the plate about three-quarters the length of the channel, simply to stiffen it sidewise. It is true I do not know of any case in which this section was used where the unit stress in the steel was over 3,000 to 4,000 lb. per sq. in. That was not economical; it was wasting steel; but it was the best we could do. I have used a 5-in. I-beam with a 4-in. channel riveted to the web. The channel has no office to perform, whatever, except to stiffen the I-beam section. The latter takes the entire loading. This section of a column is one that can be put in an ordinary 4-in. partition in an apartment building.

Recently the Lally column has come into use, which is nothing but a steam pipe filled with concrete, and it is my opinion that it might as well be filled with sand. The star-shape section, made of two angles, is very weak in one direction, on account of the very small radii.

To-day we are confronted with the proposition that we have not, nor can we build, an economical rigid section for very light loads. Take, for instance, wind bracing. It is easy enough to provide a suitable section for heavy loads, but with light loads it is a different matter. In our building designs of to-day, for instance, the columns in the top story of any building, a 5-in. **H** section would support every load, but you cannot get it and what will you use in its place? As a matter of fact, I doubt if the manufacturers of steel have kept pace with the demand for economical sections along these particular lines. I understand that the Illinois Steel Company are developing these sections, and are making rolls for a new set of beams throughout; also that they are developing some very small, light sections, and are changing the moments of inertia and the weights of standard beams from 8 to 24 in.; so that very soon we shall have a new series of steel structural shapes to figure on. This is all right for floor construction, but what I am after is something that we can use for columns and struts, which is economical; where the steel can be actually stressed up to a working limit of, say, 10,000 lb. per sq. in. Heavy column sections may be built out of a number of structural shapes, but in the light sections we are compelled to waste material, no matter what we use.

Albert Smith: I am quite unequal to suggesting any section that would be thoroughly economical in the case which Mr. Davidson mentions. We use channels, light channels, with angles at the bottom in an endeavor to make the actual fiber stress come as near as possible to that permissible in such a case. It has sometimes occurred to me that it would be possible to use a pipe section in cases of that kind. If we could get pipes 18, 20, or 24 ft. in length of thin material, and could manufacture a standard detail for the end, to be threaded onto the pipe, we might be able to carry these very light loads economically. I think we are too much afraid of doing shop work, in general; we think a little too much of the cost of coping and of blacksmith work. With us, with the very excellent machinery that we use, he cost of shop work cannot be anywhere near as great as with English manufacturers. I refer especially to the small compression members of a bridge brace—those which we now make of single angles. English designers use T-bars almost exclusively for such struts, cutting off the outstanding leg, and I think such members could be used economically as our struts. The cost of coping would not be great and we should avoid, in most cases, the gusset plate. Nine times out of ten two rivets are sufficient for a connection, and the two rivets could be driven through the remaining leg of the T-bar into the top chord.

In regard to large compression members—those to which Mr. Horton has referred—I wish that such tests could be made by the government, and that when they are made they would parallel the case of the member in the field; for instance, the vertical posts of railway bridges. It seems to me they would be better if tested in connection with the floor beams and it does not seem reasonable to get bending in that post from the floor beam attached to it. It should be [illegible] with a floor beam at the other end [illegible] [illegible] and then we might find an answer to a question which is not entirely [illegible]. What constitutes free length? I have [illegible] a set of specifications which contain three definitions: fixed at both ends, fixed at one end and free at the other, and free at both ends, [illegible] the free length [illegible] [illegible] of the [illegible] between [illegible] conditions [illegible]. I do not know what constitutes a "fixed end" [illegible] to an actual structure; it seems to me [illegible] [illegible] [illegible] the [illegible] connections [illegible] of the [illegible]. There are so many things that come into the stiffness of the member, in the connection, the yielding of the support, the rigidity of the attachment, that it seems as if a test, which would simulate actual conditions and show the actual value of the compression member under those conditions, would be very valuable. The difference in the permissive fiber stress is likely to run as high as 25% or 30%, according as you vary the free length—that is, supposing you use the ordinary formula, 16,000 minus 70 $\frac{l}{r}$, and 30% is a rather important amount in the design of your member.

I have no suggestion that bears directly upon the subject that the chairman has in mind.

Henry E. Vanderlip: In listening to Messrs. Horton and Smith, a few things have occurred to me. First, in regard to the question of wrinkling referred to by Mr. Horton. I have seen columns with that wrinkling between rivets, produced by heavy loading. There would seem to be a bulging out between the rivets, and yet the rivets had been spaced according to the so-called practice, which ordinarily is that no ¾-in. rivet—which is the standard rivet used in bridge and building construction—shall be placed at a greater distance than sixteen times the thickness of the thinnest outside piece of the member. This would mean that a ⅜-in. plate would be the minimum thickness where 6-in. spacing could be used, and a 5/16-in. plate, according to the rule, would permit not greater than 5-in. spacing. Yet, if you use that same 6-in. spacing with a ⅜-in. plate under some conditions of loading, you will get a bulging or wrinkling of the plate. According to the formula, it should not bulge. That is one of the peculiar things in the construction that nobody has ever seemed to explain.

The subject that the chairman brought up, about the advisable form of column for light loads and long lengths, is one which has not often been brought before the engineering profession. We might consider two forms: First, a post or column under four points supporting a water tank—a gravity tank—placed 25 ft. (approximately) above the roof of one of the standard warehouses as they are built in Chicago. There are all kinds of forms of columns used, and it does seem as if the engineers should agree on some standard form that seems to be the most economical for that purpose. You will see a dozen different forms to carry, say, a 25,000-gal. water tank. I have known of cast iron being used for that purpose, but personally I would not select it. I have seen two channels used so as to form, with cover plates, a box-shaped column. Then I have seen four angles with a single web plate, which we all know has unequal radii of gyration on the two axes. Then I have seen star-shaped forms, and the star may be formed by using two or four angles—two angles of sufficient area to take a light load—and increasing those two angles in thickness and in the size of the leg of the angle until we reach a point where good judgment would say you should use four angles as the load increases. I think this is a very good form of column for that purpose, for the reason that a water-tank tower is essentially a wind-braced structure. Therefore, since it is a wind-braced structure, one can arrange the position of the wind bracing horizontally and diagonally so that the question of the radius of gyration does not really enter into it. Another thing, the gusset plates can be arranged in between the angles, and the connections, from a bridge shop point of view, are about as good as can be obtained.

The other form I have in mind is a long column. Imagine a column, say, 35 ft. long, in the middle of a large and high room, with an upper floor and roof of the building carried on that long column. According to the building ordinance, if the column is to be fireproofed with tile where the tile did not aid in stiffening the column, then the radius of gyration of that column should be 1/120 of that length; or, 40 ft. being 480 in., there would be a radius of gyration of 4 in., and the engineer would select a form of column where he would have a radius of gyration of 4 in. The form is a matter of preference. Probably in a case like that the average engineer would select a box-shaped column, as it is easier and cheaper to get a radius of 4 in. with the box shape by using channels and cover plates.

J. Norman Jensen: It might be advisable for me to review some of the features of the ordinance in regard to columns. As you probably know, the ordinance formula for the allowable stress is $16{,}000-70\frac{l}{r}$, and if the column is filled with concrete, and also encased with concrete, so that there is at least 3 in. of concrete outside of the metal, there is permitted an allowable stress of $18{,}000-70\frac{l}{r}$, but not to exceed 16,000 lb. In the first formula referred to, the limiting stress is 14,000 lb. These are the highest stresses that can be used, and the limiting length of the compression member is 120 times the least radius of gyration. You will find, if you want to use an I-beam column, as is sometimes advisable, say a 6-in. I-beam, you could not use a length more than 7 ft. 2 in., and if you had an ordinary ceiling height of 10 ft., or a little more, you would have to use a 15-in. I-beam, 42 lb. per ft. This 15-in., 42-lb. I-beam would be insisted on, even for the top floor of a building where there is only a light roof load, because we have only the ordinance to go by, and that is the requirement of the ordinance. In order to meet the condition for slender columns, the Lally and the Acme columns have grown into use under the protecting wings of the ordinance. Where you would have to use, say, a 15-in. I-beam, 42-lb., you could use a Lally column or an Acme column 4½ in. in diameter, and satisfy the requirement as to length. Probably most of you know that these columns are merely pipes filled with concrete under pressure. In the city of Chicago there are two types—the older form called the Lally column, and another form called the Acme column—a recent competitor. While, of course, we cannot show any preference, we find that the details of the Acme column are considerably better.

The reason for bringing up this topic of light compression members, and the cause of this discussion about the limiting length of compression members, is that in apartment-house work in particular we want a column to fit inside of a partition. A 15-in. 42-lb. I-beam will not go inside of that partition, and so the architect and the engineer are compelled to use these round forms of columns, in order to comply with the rule in regard to limit of length. We would like to see the ordinance changed. We would like to see the limiting length increased from 120 to 150 times the least radius of gyration. This would allow the use of I-beam columns which are now practically excluded in buildings. The average round pipe column is of rather flimsy construction. There is no stiffness or rigidity about it. The use of an I-beam column for light loads will give something that is fairly stiff, and will be a section to which an I-beam can be riveted or bolted.

Tests at the Watertown arsenal, and other places, show that the radius of gyration has practically nothing to do with the strength of the column. The recent tests at Watertown arsenal show, for the lengths tested (from 25 to 175 times the least radius of gyration), that there was practically no difference in the strength. The one at 25 was just about as strong as the one at 175 times the least radius of gyration. So it seems that we are placing altogether too much emphasis on the theoretical considerations, and that we must come back to common-sense ideas and realize that in a compression member we want a good sturdy member, a member all of whose parts will work together, and not a highly theoretical member where the metal is in thin sections widely spread.

I spoke of the building ordinance and my hope that it would be changed to allow the use of I-beam columns in buildings. If such a change were made I would also suggest that the wording of the limiting length of cast-iron columns be changed. At present it reads: "The limiting length of a cast-iron compression member shall not be more than 70 times the least radius of gyration." The average layman and the person who has many other things to think about does not want to figure out the "70 times the least radius of gyration." The way that rule was obtained was this: They took the old rule of thumb of limitation of the length of a cast-iron column to 24 times its least diameter and translated it into 70 times the radius of gyration.

I do not know particularly what columns are referred to as freak columns. Sometimes we run across water-tanks carrying very heavy loads with supporting columns of single angle sections. Of course, theoretically that would seem to be all right, but it does not always look right. Outside of that I do not know of any particular instance just now.

Mr. Vanderlip: May I ask a question? Mr. Jensen remarked about the radius of gyration not having much to do with the strength; this made me think of the form of column that is used in a long boom—some of these modern long booms for derricks, 50 or 60 ft. long. They make those out of four angles, and near the ends where the blocks and pulleys are fixed they come down to possibly 8 in., back to back in both directions. Then as they go toward the centre they bow them out so that they are perhaps 16 or 18 in. wide. Would that not seem to indicate that the radius of gyration is a very important thing in there. The farther out they bow, the larger becomes the radius of gyration to take care of the bending tendency of the column.

Mr. Jensen: The point I wanted to bring out is that theoretical considerations lay large stress on the radius of gyration, but actual tests show it does not make any difference, as is shown at the Watertown arsenal—I am referring to this in particular. They took a certain type of column, and varied the ratio of $\frac{l}{r}$ from 25 to 175., and they found, so far as the load-carrying capacity of the column was concerned, that the ratio of $\frac{l}{r}$ seemed to make no difference: a long column would carry just as much as a short one. Some recent tests at the University of Illinois indicate that this radius of gyration—a thing that has troubled us ever since our student days—really has no right to trouble us. It has not much to do with the strength of the column. We have to make some allowance for it, in a way, but we should not lay as much stress on it as we do.

These tests also bring out another fact. According to the formulae for long columns, we ought to get the higher stress in the middle of the column. When the column is tested, that highest stress is not necessarily at the middle. It may be there or somewhere else.

I do not wish to discredit theoretical considerations, by any means, but to me it is more important to be guided in all these things by actual tests, and if these tests show that the radius of gyration has not much to do with the strength, we ought to throw overboard the radius of gyration.

Mr. Davidson: Mr. Jensen brought out one point that has troubled me somewhat, and that is how to make rigid connection between a floor beam and a Lally or Acme column. He also brought out in his remarks the advisability of using the I-beam. With an I-beam with floor beams riveted to it, there is rigidity to a building. In the other case there is a little steel or iron pipe filled with concrete, set up on a little cap, with no rigidity to it at all.

H. J. Burt: With reference to using I-beams for columns and also other light members, where the load is small in comparison to the section that is required on account of the rule limiting the value of $\frac{l}{r}$, I have resorted to this expedient: I have figured the radius of gyration of only the outstanding metal; that is, the flange of the I-beam. That permits one to go to a longer length for a good sized member and seems to me to be altogether permissible, provided there is enough metal in the flange to carry the load specified.

W. L. Cowles: It seems there can be no question about the cylindrical section. Probably the strongest—it must be the strongest—is the pipe section, and evidently such a form of section has been used for building construction recently, but I should imagine that it might be quite difficult to make satisfactory connections. I am not familiar with the dimensions and what the connections may be. I recall that pipe sections—in fact, actual gas pipes—were used quite extensively by the Brown Hoisting Machinery Company some years ago. The sections were prepared by putting them in the blacksmith shop and straightening out or flattening the ends. They were used in a riveted connection, and for compression members so far as they were available; also for the posts of bridges—the chords, however, being made of channels—and for lateral struts.

I have never seen this method of construction used anywhere else, and in many places it might be considered a difficult or uneconomical one as to shop work, but the Brown Company was equipped for that kind of work, and the results seemed to be very good. The pipe section certainly proved economical in construction and served the purpose very well.

I do not know whether the Brown Company is still using that section or not, but if these pipes can be utilized economically they will naturally make the best section for the [illegible]

Mr. [illegible]: It seems to me that the necessary thing to do in this matter of light column work is to take off the [illegible] length of the member. If there is [illegible] the foundation should be [illegible], it has not [illegible] that [illegible] happens there. [illegible]

[illegible]

[illegible]

portant point which is not always given the consideration that it merits. If composite members fail by wrinkling of the parts at 65% of the load that a pipe or **H** section will stand, then 35% of the maximum efficiency is lost. By spacing the rivets closer or by changing the proportion of the different parts, it may be possible to make built-up members approach nearer the strength of a solid section of equivalent area. Mr. Horton suggests that a large number of tests be made of small-sized members with variations in the relative sizes of the flange and web elements, and in the numbers and sizes of rivets. It might then be possible, from the results obtained, to recover some of the 35% lost efficiency.

Olin H. Basquin: In regard to pipe sections, I recollect that tests were made at the Watertown arsenal not long ago, perhaps within three or four years, in which Mr. Howard showed that pipe sections of moderate lengths fail practically always at their elastic limits when tested as columns. He also showed the same thing for these **H** sections, the form used by the Bethlehem Steel Company. These sections were used with square ends and were loaded very carefully. One would not expect to get such a result in actual practice because they could not be loaded as carefully in a structure as they were in the laboratory. That is one difficulty with all tests that have been made on columns, because the load which the column will stand depends very largely upon the care used in loading it, and the degree of accuracy used in getting that load at the centre of the column section.

The theory of columns is generally thought to be in a very unsatisfactory condition, but this is due to the fact that people do not pay attention to the theory that is already fairly well developed. About thirty years ago Professor S. W. Robinson, of the Ohio State University, published a paper on the strength of wrought iron bridge members, and that paper has been republished in No. 60 of Van Nostrand's Science Series. In that he gives the correct formula for maximum stress in a column, which is based on the same assumptions that are ordinarily used in the beam theory. This formula was rediscovered by Professor Marston, now of the Iowa State College, then a student at the University of Wisconsin, and was published in the Proceedings of the American Society of Civil Engineers, in connection with a paper by Dean Johnson, but Dean Johnson warned the public that this was a very dangerous theory to use in practice—for just what reason I do not know. This theory has crept into the German text-books and has been used there for a long time, but you will find it in a rather subordinate position in the better American text-books of the present time.

This theory depends upon the load on the column being a little out of centre; that is to say, it is the theory of eccentrically loaded columns and it is the true theory for ordinary columns; but in order to apply it, we must know where the load is; in the ordinary column, of course, we do not know where the load is; it may be an inch out from the axis of the column; so, in using an ordinary column formula, we are guessing how far the load is from the centre of the column. Of course, that is a short way and a convenient way of estimating columns in practice, but I want to call attention particularly to the fact that the theory of [illegible] columns are well built, is not on a particularly unsatisfactory basis. This theory was taken up by Professor [illegible], who published a book on columns and made a great many experiments on eccentrically loaded columns of rather small size. He took, particularly, a number of angles fastened together, and loaded one of the legs, and found that the deflection and failing load corresponded closely with the values which one gets from calculation.

Three or four years ago—perhaps a little longer—Mr. Buchanan published a series of tests made for one of the eastern railways—I think it was the "Panhandle." In some of those tests, which were made on the top chords of bridges loaded on the pins with a certain eccentricity, the deflections which he gives will be found to correspond almost identically with those calculated, but those columns did not fail at the maximum stress which was calculated. Why? Nearly all of them, I think all of them, failed in the details, particularly at the end plates; and I think that is true of nearly all tests of full sized columns made up of riveted shapes. They do not fail at the maximum stress figure, but they fail in the details.

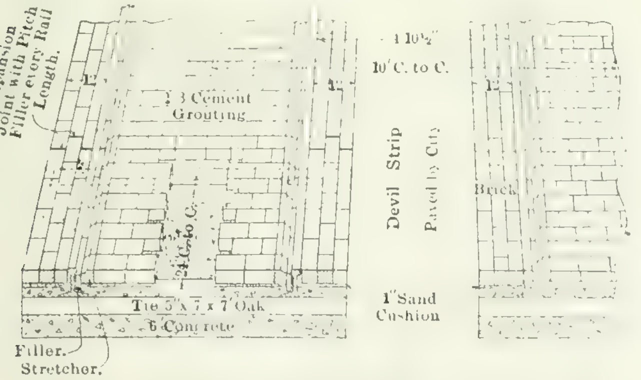
What is needed is more experiments like those recently performed at the University of Illinois, in which they were testing the strength of riveted joints. As far as the columns are concerned, it does not seem to me that there is much need of testing a great many columns in the laboratory until we know how to make the details properly, and then it is not at all certain that the tests will be of any great value, because the failure of a column depends upon how carefully it is fabricated and just how the load is applied, and to apply the load very carefully in any one position in practice is almost impossible. We cannot duplicate in practice the conditions of the laboratory, so that the results which are obtained in the laboratory will not correspond to those obtained in practice.

◆

STREET RAILWAY CONSTRUCTION.

The Des Moines (Ia.) City Railway is using for standard track construction in paved residence streets having ordinary traffic the combination of materials shown in the accompanying drawing, a description of which appeared in a recent issue of the Electric Railway Journal.

The foundation for this track consists of 6 in. of concrete below 5-in. x 7-in. x 7-ft. oak ties spaced 2-ft. centres, with 2 in. of concrete above the ties and a 1-in. sand cushion for the paving. The rails, which are the Lorain 80-335 section, 7 in. high, with 6-in. base, 2¼-in. tread and 7/16-in. web, are connected every 6 ft. by 5/16-in. x 2-in. tie rods. The interesting feature of the paving is the use of the Nelsonville (Ohio) Brick Company's filler and stretcher blocks in connection with the T-rail. The filler blocks are 2 in. x 5 in. x 9 in. and the stretcher blocks 3¼ in. x 4 in. x 9 in. in size. Pitch filler is used for the joints between them. The other paving used on the street is of cement-grouted brick, 4 in. deep, as shown in the illustration.



T-Rail with Filler and Stretcher Block, as Laid in Des Moines, Ia.

NEW WESTMINSTER'S HARBOR

Seeing that a bill will shortly come before parliament to make New Westminster a national port; that most extensive plans for the development of this port have been drawn up and the first work is being carried out; and that the development of the Pacific Coast ports is of importance to the whole of Canada, the following authoritative facts concerning New Westminster and the Fraser River, which can be relied on, are of much interest:

New Westminster is situated on the Fraser River, 18 miles from the sea.

The harbor extends from the head of Douglas Island (about 28 miles from Sandheads Lightship) down the north arm to salt water, south to the international boundary and up the south arm to Douglas Island. The length of the main deep-water channel (or south arm) is 28 miles, and 14 miles is the length of north arm for log towing and small vessels. The depth is 14 feet at low-water, and 26 feet O.S. high-water at Sandheads. When the Dominion government's work at the Sandheads is finished these depths will be 25 feet at low water and 37 feet at high-water. Along 1.7 miles of municipal waterfront there is an average depth of 40 feet.

There is 12 feet of tide at the Sandheads and 5 feet at New Westminster. Marine growth dies and falls off in the river water in ten days or so. The water is good for boilers.

Pilotage fees are $1.00 per foot of vessels' draught and 1 cent per registered ton each way, half charges if no pilot is employed.

Harbor dues are chargeable as follows on vessels of

	50	tons and under		$ .50
over	50	tons and not over	100	1.00
"	100	" "	200	1.50
"	200	" "	300	2.00
"	300	" "	400	2.50
"	400	" "	500	3.00
"	500	" "	700	4.00
	700			5.00

Dock dues are not charged; wharfage amounts to 50 cents a ton. The railway makes no charges on freight delivered from or to their own trains. One dollar a day berthage is charged where any charge at all is made.

The principal wharves are those of the Canadian Pacific Railway, 340 feet long; Canadian Pacific Navigation, 700 feet long; British Columbia Transport, 600 feet long; British Columbia Electric Railway; Great Northern Railway, and that of the Canadian Northern Railway at Port Mann, 1,000 feet long, and many other privately leased wharves. The railways, the Canadian Pacific Railway, Great Northern Railway and British Columbia Electric Railway, parallel the waterfront and run on to the wharves. The land and waterfront lend themselves to unlimited development along these lines.

Towage is unnecessary except for sailing vessels, when charge is a matter of bargain. Large vessels coal at Vancouver Island points, as they do when calling at any British Columbia port. Small supplies of coal are to be had locally. Locks are unnecessary on the river.

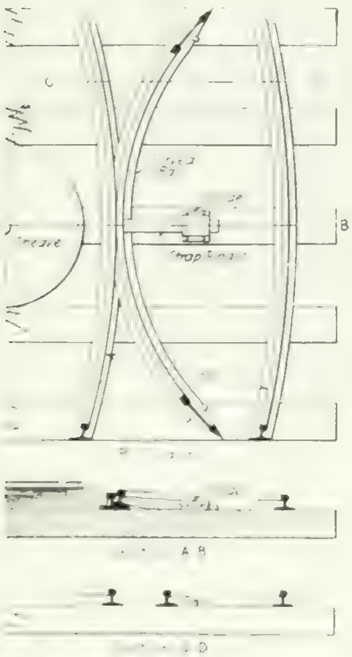
There are good machine shops and boiler works in New Westminster, capable of carrying out any repairs. The Dominion Government dredge "Fruhling" is at work at Sandheads, King Edward, on north arm. The municipal dredge will soon be at work improving the city waterfront by filling Front Street and carrying the harbor line further out to an unbroken quay over a mile in length.

The Dominion government's contract for the first 6,900 feet of three-mile jetty will be completed by April 1st, 1913, and forms part of LeBaron scheme, which will give 25 feet at low-water from the Pitt River to the Gulf of Georgia.

◆

GUIDING ROPES ON CURVES.

A rope incline which contains many curves sometimes occasions trouble by the rope catching under the rail head, when rounding the curve, and thus being thrown off the sheave. Joseph Daniels proposes an ingenious method of avoiding this trouble in Coal Age, August 24, 1912. It is as follows:



Sketch of Guide Arrangement for Use on Curves.

A section of rail, usual weight 30 lb., has its ends tapered to a wedge and is bent into a curve having a middle ordinate of 5 in. in a chord of 6 ft. This rail is placed so that its centre touches the main rail at one point and its ends are then spiked to the ties, leaving this middle point free to move. A piece of strap iron is fastened to the rail flange at the middle point and slides in a guide which is also spiked to the tie as shown.

The action of this arrangement is as follows: The cars going up or down the incline spring the curved rail away from the point of contact, thus permitting the trip to pass and immediately coming back to place after the last wheel flange has passed.

The rope at the time is approximately in the middle of the track, but its tendency will be to side over toward the [illegible] of the adjacent [illegible]. [illegible] from the middle of the track over the centre point of the curved rail [illegible]. In this way the rope is prevented from getting underneath the head of the main-track rail.

◆

TOWN-PLANNING FROM AN ENGINEERING ASPECT.

A paper on [illegible] was read by Mr. [illegible] [illegible] a subsidiary street less substantial than that in a wider street. He deprecated the practice of putting in heavy kerbing and flagged footways in residential districts, and thought that grass margins and asphalt footways not only effected a saving of cost, but presented a more rural and pleasing appearance. He thought that the road requirements of our by-laws were unreasonable, and resulted in houses being built with a narrow frontage and deep back, instead of a wider frontage and shallow back, which he considered much preferable. Open spaces should be left for parks, tennis courts, bowling greens, children's playgrounds, garden enclosures, sites for public buildings, &c. The sewerage scheme and sewage disposal were also very important matters. In a manufacturing area town-planning was different from that of a residential area, some of the points to be considered being:—(1) The position of the proposed industrial area, (2) its proximity to railway sidings. (3) the facilities for vehicular traffic to and from the area; (4) the necessity for constructing any new roads leading to this area in a substantial manner, so that they would carry the heavy traffic likely to come upon them; (5) the area to be occupied by workmen's dwellings; and (6) the supply of electrical energy for power and lighting purposes. In addition to these there would be questions of water and gas supply to be considered, and the disposal of sewage, storm-water, &c.

◆

OIL FUEL BURNERS.

At the October meeting of the New York Railroad Club a paper on the subject of liquid fuel was presented by W. N. Best. Mr. Best stated that one of the greatest abuses of liquid fuel is the fact that it is often used with burners that do not thoroughly atomize the oil and evenly distribute the heat throughout the firebox or the charging space of the furnace. A burner should really form a flame to fit the length and width of a furnace as evenly as a blanket covers a bed. It should be capable of atomizing any gravity of fuel procurable in the open market without either clogging or carbonizing, no matter whether it be fuel oil of very light gravity or crude oil, oil tar or coal tar. A burner is not worthy of consideration unless it enables the operator to burn any gravity of liquid fuel, for no manufacturer should be limited to the purchase of one particular kind of fuel oil.

A burner wherein the base of the fuel carbonizes over the fuel passage is absolutely worthless. A burner should be of such construction that it can be filed to make a long, narrow flame or a broad, fan-shaped blaze, and each burner should be thoroughly tested, so that when it leaves the shop where it is made the manufacturer will know that it will fill the requirements for which it is being furnished. A burner having the oil orifice below the atomizer orifice and independent of it renders efficient service because of there being no liability of the oil solidifying or carbonizing over the atomizer slot at the base of the burner.

A combustion chamber of adequate proportions for the uniting of the air requisite for perfect combustion with the atomized fuel before it reaches the furnace proper should be used on furnaces. This prevents oxidization of the metal charged in the furnace. It also aids in forming a blanket of flame to cover the entire charging space, thus insuring the even distribution of the flame and heat. Steam or compressed air should be used to atomize the oil and distribute the heat in the furnace, the pressure varying in proportion to the size of the furnace. Air at from [illegible] oz. to [illegible] oz. pressure admitted independently below the burner will aid in furnishing the oxygen requisite for perfect combustion.

COAST TO COAST.

Regina, Sask.—The building permits issued in this city for the month of October last have a total value of $462,725. This is over $200,000 less than the total value issued in the same month last year.

Vancouver, B.C.—Mr. P. Welch, who recently secured the contract for the construction of the Pacific and Great Eastern Railway, is making arrangements for the transportation of his supplies and equipment into the country over snow roads that are to be kept open all winter.

River St. Lawrence.—The Admiralty Court of London, England, reversed the recent judgment on the placing of the responsibility for the collision between the Canadian Pacific Railway liner "Empress of Britain" and the collier "Helvetia." By their decision the owners of the smaller vessel must assume seven-twelfths of the damage.

Toronto, Ont.—A general survey of Ontario, dealing particularly with water supply, sewage and drainage of every city, town and village except in centres of over 50,000 population is to be made by the provincial authorities through the district health officers. The latter have practically completed their preparatory work in Toronto and will start the survey about November 15th.

Moose Jaw, Sask.—Word comes from this point to the effect that contractors are experiencing considerable difficulty with workmen in their employ who claim the various Balkan States as their native land. It is thought that the return of these men to take up arms against the common enemy will be a serious drag on the completion of several contracts now being rushed.

Ottawa, Ont.—D. H. Ross, Canadian trade agent in Australia, advises the Trade and Commerce Department that though a special effort was made to interest Canadian rolling mills in regard to the supply of 146,000 tons of steel rails and fish plates for the new transcontinental railway in the Commonwealth, no tender was received. The strong domestic demand precluded Canadians from submitting offers.

Ottawa, Ont.—At a meeting of the International Joint Waterways Commission to be held in Washington on November 18th, the matters to be dealt with will include the questions of the level of the Lake of the Woods and the pollution of international waters. It is expected that both these important problems will be advanced a stage. It will be some time later, however, before either matter reaches a finality.

Big Sandy Island, Man.—A barge in tow of the tug Minerva, became waterlogged and sank at this point, which is 200 miles north of Selkirk. The cargo consisted of two cars of dynamite and one car of black powder and is a total loss. It was the property of Macmillan Bros., sub-contractors on the Hudson Bay Railway, and was to be used in the construction of the railway. High winds had prevailed for several days on the lake.

Ottawa, Ont.—An order-in-council has been passed providing that in future school lands in the three prairie provinces may be leased for the purpose of extracting fire clay therefrom. These leases will be for an annual rental of one dollar per acre, but shall not apply to school lands within a city, town or village, unless specially provided for. The term of the leases will be for 21 years, and they will be renewed for a second term of a similar period.

Wallace Harbor, N.S.—The Livingstone bridge, the longest bridge in Nova Scotia, which spans Wallace Harbor, was formally opened for traffic recently. The bridge consists of seven spans, having a total length of the steel work, with the abutments, of 771 feet. In addition to this the approaches are 2,200 feet long, making a grand total of 2,971 feet for the length of the bridge. The cost of the bridge, which was built by the local Government, was $65,000.

St. Lawrence River.—Everything is in readiness for the floating in of the first of the four huge spans which will complete the building of the double-track bridge over the St. Lawrence River at Highlands, a work which is costing the Canadian Pacific Railway $3,000,000. It will be another twelve months before the work is finally completed, despite the fact that only four of the spans have to be swung. Each of these four spans are four hundred and eight feet long.

Springfield, Man.—Henry Hudson, Pine Ridge, Springfield, has discovered an immense bed of cement rock on his 240 acre farm. The deposit is 140 feet beneath the ground surface and extends to a depth of 250 feet, the quantity being almost unlimited. The material has been tested by local experts, whose report shows it to be an excellent ingredient for the manufacture of Portland cement. Above the deposit is also an immense bed of valuable clay for brick and tile making.

Montreal, Que.—The drydock "Duke of Connaught," recently described in *The Canadian Engineer*, arrived at its final resting place in Maissoneuve Friday morning, November 1st, after a rough journey across the Atlantic. During the trip the hawsers by which it was being towed broke several times, and a great storm nearly threw the dock on the rocky shores of Cape Breton. The dock was escorted to its position by a string of tugs, bearing representatives of the Harbor Commission and the cities of Maissoneuve and Montreal.

British Columbia.—That lumbering should properly be regarded as a science and as a profession is the substance of resolutions recently adopted by the British Columbia Lumber and Shingle Manufacturers' Association and by the Canadian Forestry Association, favoring the establishment of a course in logging engineering at the new University of British Columbia. The success which has attended the agricultural colleges of Canada and the United States in equipping the farmers' sons with a scientific knowledge of husbandry, is evidence of what might be expected from similar courses devoted to logging engineering.

Ottawa, Ont.—The construction of a $200,000 bridge over the Richelieu River, in Ottawa division of the G.T.R., has just been completed. It will connect Coteau with St. Alban's, Vt., and will result in the elimination of a number of light engines now used on the local division and the substitution of heavier ones. The old Richelieu bridge was of wooden construction and could therefore not be used by heavy locomotives, which were sent around by Montreal. The new structure, however, is of steel with concrete piers and is 1,100 feet in length. It will be formally opened for traffic on November 10th.

Toronto, Ont.—Three hundred and fifty-six new members were received by the board of directors of the Ontario Motor League at their regular monthly meeting on October 31st at the National Club, Toronto. This is the largest number of members ever enrolled in one month by the association. The total membership is now considerably over the two thousand mark. The movement for good roads will continue to be furthered vigorously by the league. The directors will personally inspect the roads in the vicinity of Toronto, and they will hold a special meeting shortly for the purpose of discussing road problems and will invite as guests, W. A. Maclean, provincial highway engineer; E. A. James, York highway engineer; Mayor Hocken, and a representative from the Board of Trade. The board decided to co-operate with the Canadian Motorcyclists' Association in all matters affecting the common interests of both bodies.

St. Catharines, Ont.—A serious accident and break in the Welland Canal occurred about two o'clock November 1st, when the steamer "Samuel Marshall," owned by the Central Canada Coal Company, of Brockville, carried away the four gates of lock 13, and badly damaged the bridge crossing the canal a short distance below the lock. The Marshall was bound up, light, and on entering the lock rammed the two head gates, throwing them apart and letting the waters of the upper level rush through, tearing the upper and lower gates from their sockets and forcing the steamer back against the bridge which crosses the canal. The working gear of the bridge was badly wrecked and the bridge thrown out of position, blocking all travel along the road. Fortunately the level above is a short one, and there was comparatively little damage to the canal banks or surrounding country. The steamer escaped without any serious damage. The pontoon, with new gates, from Port Dalhousie, was at once hurried up to the break. There has been an unusual number of accidents this season on the canal, this being the fifth time gates have been carried away. It is said the high wind was partly responsible for the latest accident.

Grand Trunk Railway.—In regard to the block signal system at present being installed on some portions of the Grand Trunk Railway System for the additional safety and control of train morements, it has been decided by the company to place all construction work incident thereto, as well as the after maintenance of such, under the direct charge of one official, known as the signal engineer, who will report to the chief engineer. The signal engineer will also have similar charge of the signal and interlocking plants, on the lines of the Grand Trunk System. In a circular issued recently by the chief engineer, Mr. Charles A. Dunham is appointed to the office of signal engineer. Mr. Dunham was born in Hamilton, Ont., 46 years ago, and has had a long experience with the various systems of block signalling in use by the larger trunk lines in the United States. To meet the needs brought about by the great development of its train service in general, the Grand Trunk has been extending the use of such safety appliances on some of its lines, and it has in view the substantial increasing of such use, in order to keep pace with the needs of its general development.

SEPTEMBER RAILWAY EARNINGS.

The net earnings of the Canadian Pacific Railway in September, according to the monthly statement, showed an increase of $332,857 as compared with the same month last year. The increase while smaller than that reported in either July or August of the current year compares with a gain of only $[illegible] in the same month last year over September, [illegible]. The yield at par for the month was equal to [illegible] per cent., and net earnings for the three months show an increase of nearly 15 per cent. The September statement follows:—

	September, 1912	July 1st, to Sept. 30, 1912
Gross earnings	$[illegible]	$[illegible]
Working expenses	[illegible]	[illegible]
Net profits	$[illegible]	$[illegible]

In September, 1911, the net profits were $[illegible], and from July 1st to September 30th, 1911, there was a net profit of $[illegible]. The gain in net profits over the same period last year is therefore, for September $332,857.05, and from July 1st to September 30th $1,[illegible].

Canadian Northern gross earnings for September were $1,671,500, an increase of $95,100 over the corresponding month in 1911. The net earnings showed an increase of $4,100 for the same period, making those for 1912 to date $193,200 in excess of last year.

The Grand Trunk September statement shows net profit as follows:—Grand Trunk proper, increase, £21,550 sterling; Canada Atlantic net profit, decrease, £3,400; Grand Trunk Western net profit, increase, £4,250; Grand Haven net profit, decrease, £4,900; total net profit, whole system, increase, £17,500; one working day less.

◆

RAILROAD EARNINGS.

The following are the railroad earnings for the week ended September 21st:—

	1911.	1912.	Increase or Decrease.
C.P.R.	$2,218,000	$2,549,000	+ $331,000
G.T.R.	1,018,506	1,101,588	+ 83,082
C.N.R.	373,600	390,200	+ 16,600
T. & N.O.R.	44,592	28,146	— 16,446

The following are the railroad earnings for the week ended September 30th:—

	1911.	1912.	Increase or Decrease.
C.P.R.	$3,061,000	$3,457,000	+ $396,000
G.T.R.	1,330,952	1,464,732	+ 133,771
C.N.R.	506,000	526,600	+ 20,600
T. & N.O.R.	58,381	36,650	— 21,731

The following are the railroad earnings for the week ending October 7th:—

	1911.	1912.	Increase or Decrease.
C.P.R.	$2,396,000	$2,765,000	+ $369,000
G.T.R.	985,730	1,058,587	+ 72,857
C.N.R.	460,500	471,700	+ 11,200
T. & N.O.R.	42,582	25,019	— 17,563

The following are the railroad earnings for the week ended October 14th:—

	1911.	1912.	Increase or Decrease.
C.P.R.	$2,510,000	$2,957,000	+ $447,000
G.T.R.	995,600	1,063,161	+ 67,561
C.N.R.	480,900	523,700	+ 42,800
T. & N.O.R.	49,402	33,170	— 16,362

Aggregate traffic receipts of the Grand Trunk Railway Company for July, August and September were £2,952,240, against £2,701,975 in the same three months last year, an increase of £250,265.

◆

NEW FOREST RESERVE RECOMMENDED IN PRINCE ALBERT DISTRICT, SASKATCHEWAN.

The Forestry Branch of the Department of the Interior has again, during the past summer, had parties out examining the timber on some of the regions still in the hands of the Dominion Government, with a view to reserving from settlement lands more suitable for forest growth than for farming. Some of these parties have finished the work assigned them and have made their reports.

Mr. C. H. Morse made an examination of a district north-west from Prince Albert lying between the Shellbrook branch of the Canadian Northern Railway (on the west) and the third Dominion meridian (longitude 106 degrees), and recommends that the tract between the meridian on the east and the Sturgeon River on the west should be made a forest reserve. This land is not pure sand, but has some stretches of sand among lands of better quality; none of it, however, can be classed as good agricultural land. At the present time this tract carries, in places, a good stand of spruce, as good a stand as will be found anywhere in the country. The reproduction of the forest is good, and this should make one of the most valuable forest tracts in the west. The rate of growth is good. As it is calculated that the present stand of timber, which is held under license, will be cut out in ten years, it will be seen that the necessity for looking for a future supply is close at hand.

◆

RAILWAY AND OCEAN TERMINALS FOR HALIFAX.

The Dominion government will build new railway and ocean terminals nearly two miles south of the present terminals at Halifax.

The new docks are to extend for one and a half miles from the Lumber Yard to Point Pleasant Park, and will consist of six piers, 1,250 feet long and 300 feet in width, with capacity sufficient to dock at least thirty ships. There will be one bulkhead loading pier, 2,000 feet in length, at which the ocean greyhounds will land. This pier will be equipped with immigration buildings, sheds and a grain elevator.

A new union passenger station will be erected at the end of Hollis Street, just north of the docks mentioned, which will be of ample size and suitable architecture.

The new terminals will be approached by a double-tracked railroad, which will branch off the main line at the Three Mile House and extend southerly through the low divide between Bedford Basin and the head of the northwest arm. It will then skirt the arm in such location as will do the least damage to property in that vicinity, avoiding all level crossings, and for the most part passing through deep cuttings so as not to mar the beauty of that district, and finally reaching the terminals by passing under the lower end of Young Avenue. The streets in the residential district where the railway is submerged will be carried over the cutting on artistic bridges in keeping with the present surroundings.

◆

THE CANADIAN SOCIETY OF CIVIL ENGINEERS.

Professor C. H. McLeod, secretary of the Canadian Society of Civil Engineers, has sent out the list of nominees for officers and members of the council for the year 1913, as submitted by the Nominating Committee of the Society. It will be observed that with the exception of the nomination for president, two members are proposed for each office. There are three vacancies in District No. 1, and one in each of the other districts. The extra vacancy in No. 1 is caused by the resignation of Mr. Phelps Johnson, who has been nominated for the office of president.

FOR PRESIDENT—Phelps Johnson.

FOR VICE-PRESIDENT—H. G. Kelley, F. C. Gamble.

FOR COUNCILLORS—

District No. 1—R. J. Durley, J. M. R. Fairbairn, W. J. Francis, Geo. Janin, F. H. Pitcher, J. M. Robertson.

District No. 2—F. A. Bowman, T. C. Burpee.

District No. 3—A. R. Decary, W. D. Baillairge.

District No. 4—S. J. Chapleau, A. A. Dion.

District No. 5—H. E. T. Haultain, C. H. Mitchell.

District No. 6—E. P. Fetherstonhaugh, W. A. Duff

District No. 7—H. E. C. Carry, T. H. White.

PERSONAL.

MR. R. J. FULLER, B.A.Sc., has been appointed to the staff of the city architect's department in Toronto.

MR. T. AIRD MURRAY, consulting engineer, has returned to Toronto after an extended trip through the West

MR. W. J. ELMENDORF is in charge of the property of the Portland Canal Tunnels, Limited, in the Portland Canal district, British Columbia, as general manager.

MR. ROBERT D. HEDLEY, formerly manager for the Canadian Mining Operators, Limited, Vancouver, B.C., has opened an office in Vancouver as consulting engineer.

PROFESSOR WALLACE P. COHOE gave an address on "The Function of the Chemist in the Industrial Development of Canada," before the Society of Chemical Industry in Toronto on October 31st.

PROFESSOR R. J. DURLEY, M.Inst.C.E., of McGill University, Montreal, Que., has been awarded the Crampton prize of the Institution of Civil Engineers of Great Britain for a paper presented during the 1911-1912 session.

MR. D. H. McDOUGALL, assistant general manager of the Dominion Coal Company, has been appointed to the general managership of that company, which position has been rendered vacant by the resignation of Mr. J. Butler.

MR. H. P. BELL, late of London, England, has opened an office in Toronto as consulting chemical engineer, with temporary quarters at 409 Kent Building. Mr. Bell will undertake inspections and reports on industrial processes and plants.

MR. F. A. DALLYN, B.A.Sc., of the Ontario Board of Health, is at present taking samples of water from Lake Huron, the River St. Clair and Lake St. Clair. It is understood that the results of the analyses will be used before the International Joint Commission when the Provincial Board of Health present their arguments regarding lake pollution.

MR. HARRY DIX, for the past two years in charge of the heating and ventilating department of the Douglas Milligan Co., Limited, has severed his connection with that firm to join the engineering staff of the Canadian Domestic Engineering Co., Limited. Mr. Dix is a Boston man who came to Canada for permanent residence several years ago and has a number of friends in and around Montreal. He is well fitted for the responsibility of his new position and the connection should prove mutually beneficial.

MR. C. A. DUNHAM, who has been appointed signal engineer for the Grand Trunk Railway System, received his earlier education in Hamilton, Ont., which was supplemented by educational work at Scranton, Pa., and Chicago, Ill. He entered the railway service in 1884, since which time and up to 1886 he was with the mechanical department Chicago, Burlington and Quincy Railroad, at Chicago; April, 1886 to 1887 in bridge department, New York, Chicago and St. Louis Railroad; in 1887 he was for several months with the U.S. Rolling Stock Company at Hegeswich, Ill., following which he became connected with Grand Bros., railroad contractors, serving in this capacity until January, 1890. From January, 1890, to September, 1892, was in the operating department of the Chicago, Burlington and Quincy Railway. September, 1892, to March, 1896, with the Union Switch and Signal Company, and the National Switch and Signal Company; March, 1896, to March, 1901, inspector of signals, Illinois Central Railroad; March, 1901, to June, 1905, signal engineer same road; June, 1905, to date, signal engineer, Great Northern Railway.

OBITUARY.

PETER H. HUME, C.E., one of the best-known structural engineers in America, and business associate of Michael Connolly, of Ontario, died at St. John, N.B., on November 3rd last after a long illness during which he had kept at work. He had supervised the construction of great docks at Hong-Kong, Buenos Ayres, New York and the subway in Philadelphia. His widow and one daughter, Mrs. C. E. Duggan, of St. David's, Ont., survive.

◆

COMING MEETINGS.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Monthly Meeting will be held in the Rooms of the Society, 413 Dorchester Street West, Montreal. November 7th. Paper on "The Protection of the Foreshore at Dallas Road, Victoria, B.C.", by Mr. G. N. Duncan, Jr., C.S.C.E. will be read. Discussion on the effect of sea water on Portland Cement Concrete Structures will follow the reading of the paper. Chairman, Henry Holgate.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Annua Convention to be held at Dallas, Texas, November 12th to 15th, 1912. Secretary A. P. Folwell, 50 Union Square, New York.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—7th Annual Convention, November 14th, 1912, City Hall, Toronto. Secretary, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. Saturday Evening Lecture, Nov. 23rd, at 8 o'clock. "The Prevention of Sewage Pollution relative to Water Supply," by T. Aird Murray, C. E., Toronto. Secretary, J. Patterson.

NATIONAL ASSOCIATION OF CEMENT USERS.—December 12th to 18th. Annual Convention, Pittsburgh, Pa. President R. L. Humphrey, Harrison Building, Philadelphia, Pa.

AMERICAN CIVIC ASSOCIATION.—Annual Convention will be held at Baltimore, Md., November 19th to 22nd. Secretary, Richard B. Watrour, Union Trust Building, Washington, D.C.

AMERICAN RAILWAY ASSOCIATION.—Nov. 20th. Annual Meeting at Chicago, Ill. Secretary, W. F. Allen, 75 Church St., New York.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. Secretary, E. L. Power, 150 Nassau St., New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

TENDERS.

Calgary, Alta. Tenders for the construction of an examining warehouse will be received until November 15th, 1912, by R. C. Desrochers, Secretary, Department of Public Works, Ottawa. Plans, etc., at the offices of Mr. H. E. Matthews, Superintending Architect of the Dominion Public Buildings in the Province of Manitoba, Winnipeg, Man.; Mr. W. T. Mollard, Clerk of Works, Regina, Sask.; at the post-office, Calgary, Alta., and at the Department of Public Works, Ottawa.

Dunnville, Ont.—Tenders for a turbine pump installation for domestic and fire purposes will be received until November 18th, 1912, addressed to B. L. Edgecombe, chairman of the Water Commission for the town of Dunnville. Alan Mair Jackson, Superintendent. (See advertisement in Canadian Engineer.)

Edmonds, B.C.—Tenders for the construction of a concrete covered reservoir for the municipality of Burnaby, will be received until November 11, 1912, by W. Griffiths, comptroller, Edmonds. Particulars may be obtained at the office of the engineers, Cleveland and Cameron, 1,001 Rogers' Building.

Fernie, B.C.—Tenders will be received by the Director of Contracts, Department of Militia and Defence, Ottawa, until November 21st, for the construction of a new drill hall at Fernie, B.C. Specifications, etc., at the office of the officer commanding military district No. 11, Victoria, B.C., and the City Clerk, Fernie, B.C., and the Director of Engineer Services, headquarters, Ottawa.

Fredericton, N.B.—Tenders will be received until noon of December 2nd, 1912, for the construction of the substructure of the Reversible Falls Bridge, St. John, N.B. Plans, etc., at the Provincial Government Rooms, St. John, N.B., and at the Provincial Public Works Department, Fredericton, N.B. John Morrissy, Chief Commissioner of Public Works. (See advertisement in Canadian Engineer.)

Montreal, P.Q.—Tenders shall be received by the sectary of the Municipality of Amqui, Que., until November 11th, 1912, on the sale of a Worthington centrifugal pump to raise 700 gallons per minute at a total dynamic head of 185 feet. Pump shall be directly connected on a 60 horsepower triphased motor, 60 cycles, 550 volts. An automatic current cutter shall also be furnished; this cutter to work by means of a contact when the reservoir is full. For further information apply to J. Emile Gill, C.E., Room 43, 20 St. James Street, Montreal.

Ottawa, Ont.—Tenders addressed to the Postmaster-General will be received at Ottawa until noon of December 13th, 1912, for the conveyance of His Majesty's mails on a proposed contract for four years, six round trips per week over Aurora rural mail route. Particulars may be obtained at the post-offices of Aurora, Vandorf, Newmarket, White Rose, and at office of Post-office Gormley, Pleasantville, Bethesda. (See advertisement in Canadian Engineer.)

Ottawa, Ont.—J. D. McLean, Assistant Deputy and Secretary, Department of Indian Affairs, will receive tenders until November 12th, 1912, for 28,000 cedar railway ties, one-half of this number No. 1 and the remainder No. 2; also 8,500 cedar posts and 250 cords soft wood.

Ottawa, Ont.—Tenders addressed to G. J. Desbarats, Deputy Minister of the Naval Service, Department of the Naval Service, Ottawa, will be received until November 12th, 1912, for the following descriptions of timber: Birch, cedar, spruce, pine, oak, fir, teak, all being for delivery at H.M.C. dockyards at Halifax, N.S., and Esquimalt, B.C.

Regina, Sask.—Tenders for the erection of a telephone building on lots 21, 22 and 23 in block 309, Regina, will be received until November 14, 1912. Plans, etc., at the office of Messrs. Storey and VanEgmond, architects, Regina. D. C. McNab, Deputy Minister, Railways, Telegraphs and Telephones.

Three Rivers, Que.—Tenders for the construction of a public building will be received until November 25th, 1912, by R. C. Desrochers, Secretary, Department of Public Works, Ottawa. Plans, etc., can be obtained at the offices of Mr. Charles Lafond, architect, Three Rivers, Que.; R. L. Deschamps, Esq., 103 St. Francois Xavier Street, Montreal, and at the Department of Public Works, Ottawa.

Toronto, Ont.—Tenders will be received by Messrs. Darling & Pearson, architects, 2 Leader Lane, Toronto, up till noon, November [illegible]th, 1912, for all the various trades in the erection and completion of a two-story bank building on the north-east corner of College and Bathurst Streets, Toronto, for the Metropolitan Bank. Plans, etc., may be obtained at the office of the architects.

Vancouver, B.C.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until November 18, 1912, for electric elevators for the Customs examining warehouse, Vancouver, B.C. Plans and specifications to be seen on application to Mr. E. E. McGregor, clerk of works, Vancouver, examining warehouse; Mr. H. E. Matthews, supervising architect, Winnipeg, Man.; and at the Department of Public Works, Ottawa.

Victoria, B.C.—Tenders for the erection of a school at Campbell River will be received up to noon of Wednesday, November 13th. Tenders for the erection of a lockup at Enderby will also be received until the same date.

Victoria, B.C.—Tenders will be received by W. Galt, purchasing agent, city hall, Victoria, until November 25th, 1912, for 12,000 ft. or more, 10-pair No. 16 cable; 2,000 ft. or more No. 16 duplex cable. Specifications can be seen at the purchasing agent's office. C. H. Rust, city engineer.

Wallaceburg, Ont.—Tenders for the construction of a public building will be received until November 20th, 1912, at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa. Plans, etc., at the post-office, London, Ont.; post-office, Wallaceburg, Ont., and at the Department of Public Works, Ottawa.

Winnipeg, Man.—Tenders for the manufacture, delivery and installation of one horizontal boiler at the high-pressure pumping station, James Avenue, will be received until November 15th, 1912, addressed to the chairman, Board of Control. Specifications, etc., at the office of the City Engineer, 223 James Street; M. Peterson, Secretary, Board of Control office, Winnipeg.

Winnipeg, Man.—Tenders for the manufacture and delivery, f.o.b. cars, Winnipeg, of 22,000 ft. of lead covered rubber insulated cable, will be received until noon of Friday, November 15th, 1912. Particulars may be obtained at the office of the City Light and Power Department, 54 King Street. M. Peterson, secretary, Board of Control office, Winnipeg.

◆

CONTRACTS AWARDED.

Harriston, Ont.—The Harriston town council have awarded contracts for the instalment of the new electric light plant, which is expected to be in operation by December 15th, as follows: Engine, Messrs. Leonard & Sons, London; generator and all electric outfit but street lamps, the Westinghouse Co., Limited, Hamilton; street lights, the Philadelphia Electric Manufacturing Co., through Winter & Joyner, St. Catharines. The total estimated cost of the new system is $[illegible].

New Westminster, B.C.—The Shaake Machine Works have received an order for the construction of a [illegible] dredge to be used in gold dredging operations on the Fraser River, near Hope. The dredge will cost about $[illegible], and will be ready by the first of April.

Ottawa, Ont.—A contract has been awarded to the [illegible] Dredging Company for dredging work at Port [illegible], to cost $[illegible].

Regina, Sask.—The contract for the erection of the new [illegible] has been awarded to the [illegible] Construction Company, who will [illegible] for the sum of $[illegible]. The Regina Plumbing and Heating Company will install the lighting, heating and power systems.

Vancouver, B.C.—The Norton Griffiths Steel Construction Company, Limited, have been awarded the contract and have already commenced work on the Merchants' Ice and Cold Storage Company's warehouse. The building will be [illegible] feet long, [illegible] feet wide and [illegible] in height, and will have a [illegible] basement. Reinforced concrete will be used in construction throughout. It will be fitted with rolling doors and patent sprinkler system, and will be entirely [illegible] in every respect. The cost will be $[illegible]. Mr. [illegible] is the architect. Messrs. Norton Griffiths have been awarded the contract for a new machine shop for the [illegible] Naval Dockyard, to be erected at a cost of $[illegible]. Mr. [illegible] is the engineer.

RAILWAYS—STEAM AND ELECTRIC.

Edmonton, Alta.—It was announced in this section of the Canadian Engineer some months ago that a company financed by French capital were negotiating for a charter to erect and operate a railway to be known as the Peace River Great Western Railway. Word has been received to the effect that the management have secured their charter and are making all arrangements for an early start on the construction. The first section will run north-west from Edmonton The original charter was granted Robert Alfred Grant, Robert Henry Percival and other Winnipeg men. The capital stock of the company is $2,500,000 and bonding powers of $20,000 a mile are granted.

◆

LIGHT, HEAT AND POWER.

Esquimalt, B.C.—The municipal council will call tenders for the installation of an electric lighting system. The council, on the receipt of tenders, will obtain the advice of a solicitor and an engineer.

Niagara Falls, Ont.—The Canadian Niagara Power Company will spend a million and a quarter dollars to construct a new forebay at its power-house in Queen Victoria Park. The company plans to have the enlarged forebay completed in 1915.

Peterboro, Ont.—Arrangements are being made to have the ratepayers vote on a hydro-electric by-law calling for the expenditure of $118,000. The voting will be done in January next.

Regina, Sask.—The ratepayers will be asked to sanction a by-law calling for the erection of ornamental lighting standards in the business section at a cost of $80,000. A. E. Chivers, city clerk.

Regina, Sask.—Commissioner Thornton has proposed a scheme calling for the erection of a new power house to cost $500,000. The routine expenditure for electric light and power house extension for next year, if the old plant is retained, will be as follows:

One complete 1,500 unit and equipment	$40,000
Additional boilers, to furnish power for the new unit	28,500
Poles and wiring	75,000
Extension of street lighting	20,000
Meters	20,000

Regina, Sask.—The following is a list of expenditures in the estimates of the fire chief for the year 1913:—

One auto pumping fire engine	$9,000
One auto double tank chemical engine	4,500
One chief's auto	2,200
2,000 feet high pressure hose at $1.60	3,300
One Hart cellar pipe	135
1,000 feet fire hose at $1.10	1,100
One Bowder life net	200
One life gun	25
Three hose holders	300
Three Cooper hose jackets	120
Two smoke protectors	200
Ten fire alarm boxes	625
One hose sleigh	225
One [illegible] fire hall	10,000
Sundries	500
Gong and equipment	150

A. E. Chivers, city clerk.

Township of Louth, Ont.—A large meeting of ratepayers, after hearing addresses from officials of the Hydro-Electric Commission, requested that body to prepare an estimate of costs regarding the installation of this utility into the neighborhood. Messrs. J. H. Broderick, L. Haynes and A. C. Gregory were appointed a committee to represent the ratepayers.

◆

GARBAGE, SEWAGE AND WATER.

Galt, Ont.—The municipal council have decided to install additional hydrants on some of the streets. C. D. Campbell, town engineer.

Halifax, N.S.—Mr. F. W. W. Doane, city engineer, states all is in readiness for the commencement of the temporary sedimentation tanks to be erected in this city.

Barrett Specification Roofs

Shove Mills, Fall River, Mass. Roofed along lines of the Barrett Specification in 1876.

Low Cost—Long Service

METAL roofs require painting every few years; most ready roofings require coating regularly, but with Barrett Specification Roofs *there is no maintenance expense.*

Barrett Specification Roofs are roofs of coal tar pitch and tarred felt, with a top surface of slag, gravel or tile, *laid according to the Barrett Specification.*

This specification is simply the standard formula for building a first-class roof of this character.

It is possible, of course, to make an inferior roof of these materials either by poor workmanship or by using insufficient and poor goods. But if the Barrett Specification *is followed absolutely and the materials called for are used,* you are certain of getting the best value in roof coverings.

Such roofs usually last twenty years and over without leaks or repairs.

Barrett Specification Roofs are almost universally used on factories and buildings of large roof areas and where costs are carefully figured. They are equally good for city dwellings, warehouses, railroad buildings, etc.

Copy of the Barrett Specification, with diagrams, mailed free on request to nearest office.

Special Note

We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired however the following is suggested.

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15, 1911, using the materials specified, and subject to the inspection requirements.

THE PATERSON MANUFACTURING CO., LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER ST. JOHN, N.B. HALIFAX, N.S.

Victoria, B.C.—The Provincial Government has agreed to make a grant of $20,000 for the construction of the bridge at Brilliant, which will connect the Doukhobor settlement at that place with the transcontinental highway.

Winnipeg, Man.—The site for the new 20,000,000 gallon reservoir in connection with the extension of the city well system, has been definitely chosen by the board of control in the old triangular park in the rear of the main pumping station and power sub-station at the corner of Logan and McPhillips. The reservoir will be close to the pumping station.

◆

BUILDINGS AND INDUSTRIAL WORKS.

Berlin, Ont.—The directors of the Economical Fire Insurance Company will erect an office building in this city at a cost of several thousand dollars. W. H. Schmalz is the manager of this concern

Brockville, Ont.—Frank Donnelly, of the Donnelly Wrecking Company, Kingston, will start laying out for the contractors the cribs for the new wall to replace the concrete wall of the breakwater that collapsed a year ago. McCool & Moffatt, of Pembroke, Ont., secured the contract at $15,000. The wall will be built of timbers.

Camrose, Alta.—The Public School Board of this municipality will spend ten thousand dollars on the equipment of rooms for instruction of household arts, manual training, on an assembly hall. R. D. Fleming, Town Clerk.

Kingston, Ont.—The Kingston Automobile Company, under the management of Norris & Wafer, have purchased the Salvation Army barracks, on Queen Street, and it is their purpose to turn the premises into a first-class garage.

Medicine Hat, Alta.—Messrs. T. F. Dawson & Co., real estate brokers, have recently completed negotiations whereby a firm of New York financial men will erect a new hotel and a theatre in this city.

Montreal, P.Q.—The management of the Atlas Glass Plant have made extensive land purchases in the vicinity of this city, and will commence the erection of a factory for the manufacture of their products. It is expected that the new [illegible] by April 1st next and will employ about 700 men at the commencement.

Montreal, P.Q.—The management of the Imperial Tobacco Company will erect a two-story fire-proof factory in St. [illegible]

Nelson, B.C.—Owing to the increased interest in platinum mining in this district it is probable that one or two experimental plants for the commercial treatment of the ore will be erected. Mr. R. J. Elliot is interested in the project.

Port Arthur, Ont.—The Alberta Land Co., H. J. Powers, engineer, will erect a 2-story store and office building, [illegible] Bay and N[illegible] [illegible], $40,000.

Port Mann, B.C.—Arrangements have been made by the Canadian Northern Railway with an eastern Canadian car company to establish car works at Port Mann, B.C., one of the Pacific terminals of the C.N.R. system. The plant will have a capacity of at least [illegible] a day. It is expected that tenders will be called in a short time for this and other [illegible] at this point.

Regina, Sask.—[illegible]

Sudbury, Ont.—[illegible]

Toronto, Ont.—[illegible]

Vancouver, B.C.—[illegible]

Winnipeg, Man.—[illegible]

Welland, Ont.—The high school board have requested the council to furnish the sum of $1,700 to be used in an extension to the building. Geo. R. Boyd, town clerk.

◆

BRIDGES, ROADS AND PAVEMENTS.

St. Catharines, Ont.—Mr. N. W. Gowan, inventor of the canal lock safety device, has been awarded the first contract on the newer Welland Canal. He will put down test-holes 800 feet deep at the location of each of the locks. Work will be begun as soon as possible at the new harbor on Lake Ontario.

◆

FIRES.

Montreal, P.Q.—Fifteen thousand dollars is the estimated damage caused to the premises of the Elite Hat Works, Nos. 8 and 10 Bleury Street.

Montreal, P.Q.—The plant and premises of the Consumers' Cordage Company was destroyed by fire. Loss, $300,000.

◆

CURRENT NEWS.

Galt, Ont.—The ratepayers endorsed a by-law that will grant a loan of $15,000 to the management of the Galt Shoe Company.

Hamilton, Ont.—It is reported that the Doherty interests of Pittsburg will assume control of the Manufacturers' Natural Gas Company. It is further reported that $650,000 is the consideration paid to the stockholders.

Montreal, P.Q.—The great dry dock, which was successfully towed across the Atlantic, was safely docked in the harbor of this city early in the morning of November 1st. The three Dutch tugs which did the towing are said to be marvels as seagoing tractors.

Montreal, P.Q.—The new jail, one of the largest on the continent, is now ready for occupancy, and the first of the prisoners to be lodged there will be transferred in the course of a day or so. The construction of the building gives the appearance of an immense cross with a dome rising from the central portion.

Moose Jaw, Sask.—Industrial Commissioner C. E. Brown announces that three new industries will locate in this city in the near future. The first of these is that of the Railway Accessories Company, the second the Soap Lake Soap Company, and the third is the Alberta Glass Bottle Company.

Nelson, B.C.—The members of the grand jury have framed a resolution which, if carried into effect, will call for the erection of a new jail. Mr. Justice Gregory has the matter in hand for the present.

Province of Nova Scotia.—It is reported that the owner of certain extensive coal fields in this province is in negotiation with the Metropolitan Gas Company, of London, England, in regard to the supply of that corporation with gas coal.

Peterboro', Ont.—The Militia Department of the Federal Government have recently purchased 500 acres of land near this point and will erect a rifle range on the same.

Peterboro', Ont.—The ratepayers voted in favor of extending a bonus to the management of the Delaval Dairy Supply Company as an inducement to locate a plant at this point.

Peterboro, Ont.—Several townships adjoining this municipality have [illegible] a writ against the council for alleged pollution of the [illegible] River with sewage matter.

St. Catharines, Ont.—Another serious accident was caused in the Welland Canal by a ship striking and breaking a lock gate.

Sault Ste. Marie, Ont.—Certain property owners in the vicinity of the steel works have held a meeting and arranged a scheme calling for the erection of a model village. It is expected that Mr. H. E. M[illegible] will plan the work.

Welland, Ont.—Building permits for month of October this year are $[illegible]. Building permits for month of October last year were $[illegible]. Total for year to end of above month is $[illegible].

Windsor, Ont.—The ratepayers voted in favor of spending the sum of $[illegible] for [illegible] fire engine. M. E. [illegible], city engineer.

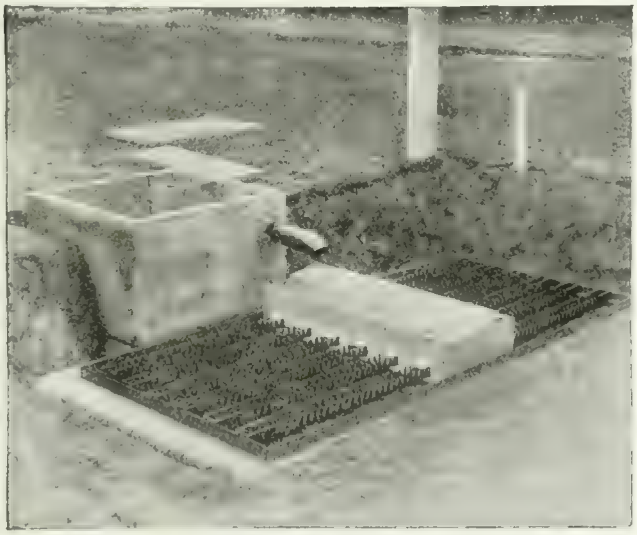
THE "SEMI-SEPTIC" SEWAGE PLANT

THE BEST SYSTEM OF PURIFYING SEWAGE, FOR COUNTRY HOUSES, OR ANY ISOLATED BUILDINGS



FROM J. M. GORHAM, ESQ. DROVE HOUSE, SINGLETON, SUSSEX

September, 1911.

Dear Sirs,

"I am very pleased with the system you have put in for me. It is really as good as it possibly can be, and I cannot understand anyone going on with the old cesspool system.

I have never seen purer effluent from any Septic System, and there is not the slightest smell in the fields."

Penhale Semi-Septic Installation.

Truro, May 10th, 1912.

Dear Sirs,

In further reply to your letter of the 2nd inst., we beg to say that we yesterday made a careful inspection of this Plant and the working thereof, and have now the pleasure to enclose our final certificate.

We find that the Installation has worked for the last six months without a single hitch or complaint of any sort, and is in perfect order and most satisfactory in every way

We beg to congratulate you on your success.

Yours faithfully,
HENDERSON & SON
(ARCHITECTS)

TUKE & BELL, LTD.

69 LEADENHALL ST., LONDON, E.C.

AGENTS FOR CANADA: LAURIE & LAMB

211 BOARD OF TRADE BUILDINGS, MONTREAL

CONSUMERS' GAS COMPANY'S REPORT.

The gross receipts of the Consumers' Gas Company, Toronto, for the year ended October 1st, 1912, were as follows:—

Gas sales	$2,058,140 63
Coke sales	253,709 97
Tar sales	32,415 12
Ammoniacal liquor	41,007 60
Consumers' Supplies and maintenance.	78,370 18
Office rents	724 96
	$2,464,368 46

The net earnings were $718,134 as contrasted with net earnings for 1911 of $697,006.

Income from other sources brought the total to $821,096.05. After paying dividends of $438,309, the sum of $382,786 has been transferred to plant and buildings renewal fund, the total amount at the credit of that account being $978,759, against $851,477 a year ago.

The output of gas for the year ended September 3rd has amounted to 3,119,748,000 cubic feet, an increase over the output of the previous year of 276,707,000 cubic feet. Gas rental for the year was $2,058,140, compared with $1,857,071 the previous year, an increase of $201,069.

President Austin, in his report, states that this is the first complete year during which gas has been sold at the present reduced price, and the reduction of five cents per 1,000 cubic feet has amounted on the output of gas for the year to about $151,000.

The following is the statement for the past, as compared with the preceding year:—

	Meters.	Gas Rental.
1912	82,022	$2,058,140.63
1911	72,544	1,857,071.01
Showing an increase of	9,478	$ 201,069.62

The current expenses total $2,464,368 and the total liabilities are shown as $8,756,749.

The company's assets are as follows:—

Works, plant and general outlay	$8,070,327.48
Main pipes, specials and lead	61,376.88
Service pipes, fittings, etc	14,729.28
Consumers' supplies	57,646.12
Coal	118,396.09
Gas oil	6,880.61

At the annual meeting of the company on Tuesday, the president, Mr. A. W. Austin, presented the sixty-fourth annual report, together with the financial statements, as outlined above, which were adopted.

The following gentlemen were re-elected directors for the ensuing year:—Messrs. A. W. Austin, A. H. Campbell, Wellington Francis, K.C., F. LeM. Grasett, M.D., John Hoskin, K.C., LL.D., D.C.L., Herbert Langlois, and Thomas Long, Sir Edmund Osler, M.P., and Sir Wm. Mortimer Clark, K.C., LL.D. At a meeting of the board held subsequently, Mr. A. W. Austin and Mr. Wellington Francis, K.C., were re-elected president and vice-president respectively.

[illegible]

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending October 21st, 1912:—

A Scottish firm manufacturing cast-iron soil pipe desire to appoint agents in Western Canada.

An engineer at Manchester is open to act as buying agent for Canadian importers of electrical goods.

A London firm are anxious to secure supplies of a waste product of the wood pulp industry, and would like to be placed in communication with manufacturers in Canada.

A Danish firm make inquiry for the names of Canadian millers wishing to ship flour to Scandinavia. They would also like to import other Canadian products for which they could develop a market.

A firm of match manufacturers in the Netherlands require supplies of Canadian pine, and would like to receive correspondence from shippers in the Dominion.

A Vancouver firm manufacturing chemical specialities are desirous of taking up agencies for lines which could be worked in conjunction with their own business.

From the branch for City Trade Inquiries, 73 Basinghall Street, E.C.:—

A Midlands firm manufacturing bicycle and motor spokes and nipples for building wheels are open to appoint suitable Canadian resident agents.

VOLTA'S ELECTRICAL APPARATUS.

A discovery of particular interest to electrical engineers was recently made by Sir Henry Norman, M.P. (English), while enjoying an automobile tour in Italy. The party stopped at a small shop situated in one of the back streets if a little Italian village, and, while other members examined the quaint wares offered for sale, Sir Henry Norman commenced the examination of a cupboard in the rear of the premises. There he came across what he believes to be many of the apparatus and material used by Volta in his experiments which resulted in the discovery of "voltaic" electricity. further examination revealed the fact that the cupboard contained a number of personal articles at one time the property of the scientist, together with a number of his letters, books, papers and pictures.

He photographed what appeared to be the original "Crown of Cups," as Volta named his first one fluid primary battery, and made a severe examination of all the other apparatus.

The keeper of the little shop informed him that an uncle of his grandfather's was for thirty years Volta's cook and man servant, and upon the death of the scientist the apparatus was left to him, and they have since been passed on from father to son, the present possessor being an old man in frail health.

Sir Henry Norman, in an article to the London Times, suggests that, should the genuineness of the objects be established beyond dispute, it would be a gracious act for some wealthy man of scientific tasts to purchase the collection and present it to the Royal Institution, where it could find a permanent resting place at the side of Faraday's original apparatus.

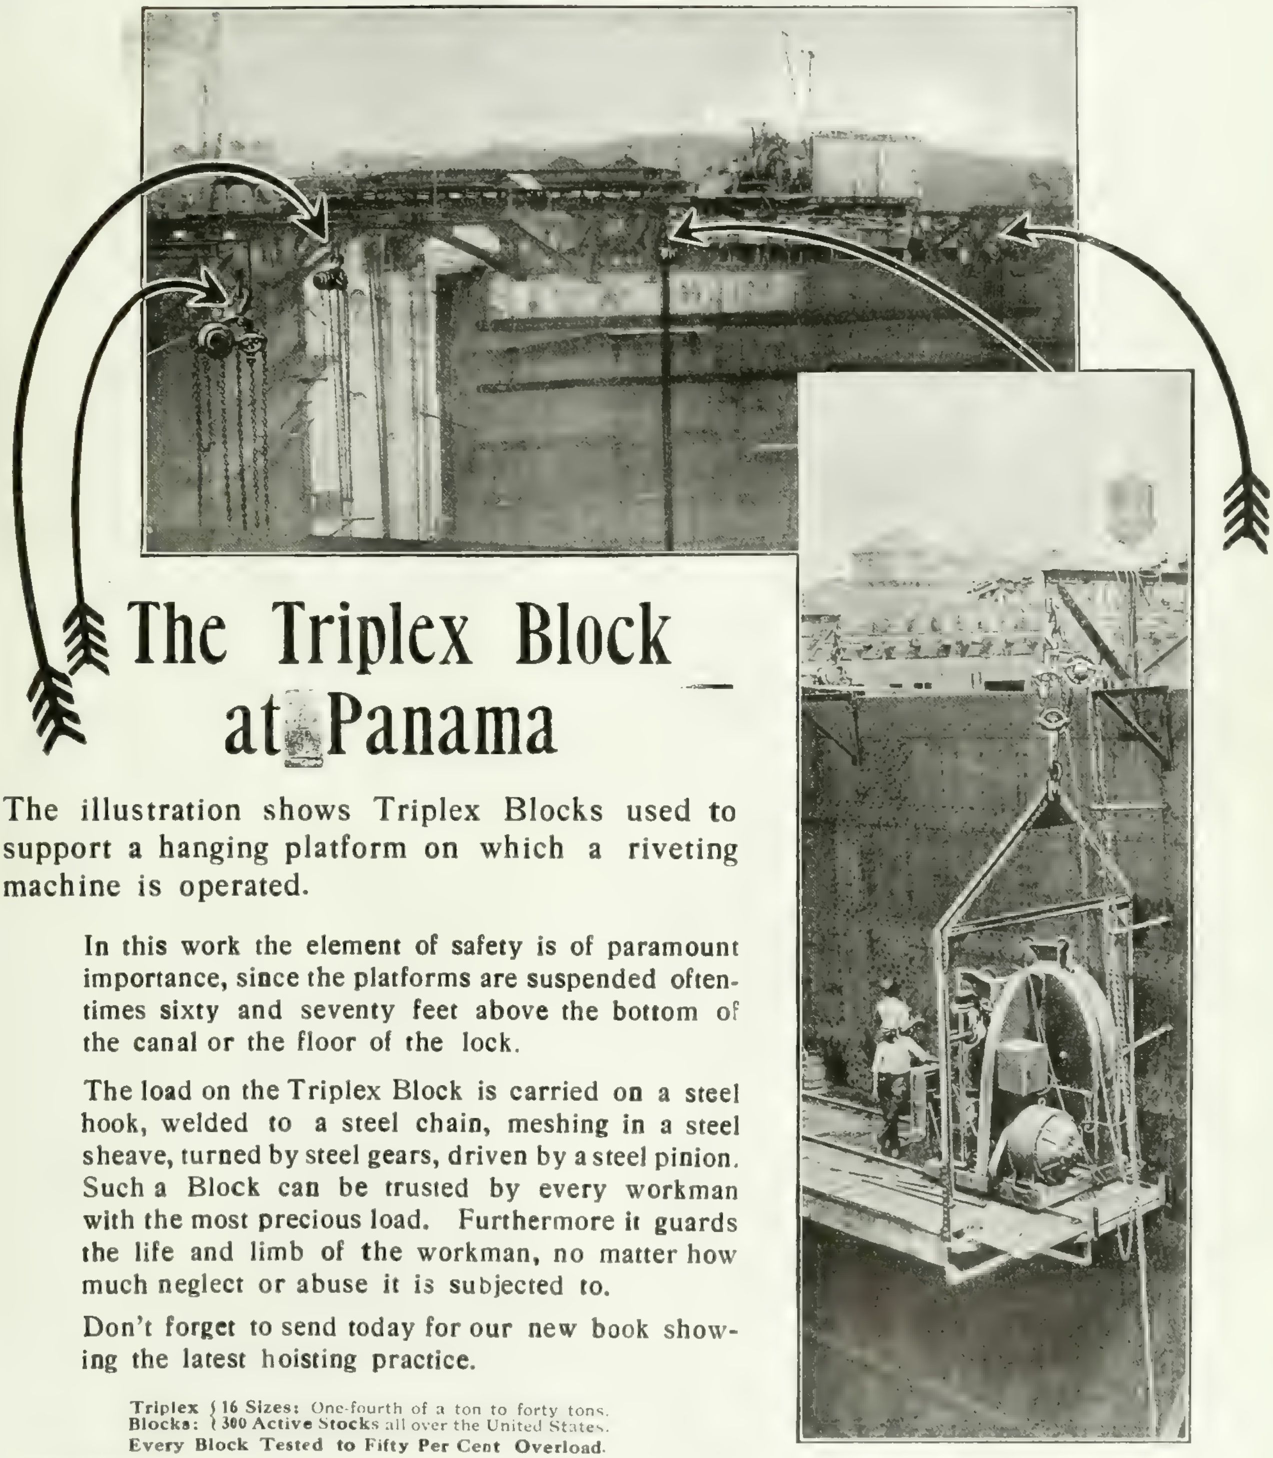
THE TRIPLEX BLOCK



The Triplex Block at Panama

The illustration shows Triplex Blocks used to support a hanging platform on which a riveting machine is operated.

In this work the element of safety is of paramount importance, since the platforms are suspended oftentimes sixty and seventy feet above the bottom of the canal or the floor of the lock.

The load on the Triplex Block is carried on a steel hook, welded to a steel chain, meshing in a steel sheave, turned by steel gears, driven by a steel pinion. Such a Block can be trusted by every workman with the most precious load. Furthermore it guards the life and limb of the workman, no matter how much neglect or abuse it is subjected to.

Don't forget to send today for our new book showing the latest hoisting practice.

Triplex Blocks: { 16 Sizes: One-fourth of a ton to forty tons.
{ 300 Active Stocks all over the United States.
Every Block Tested to Fifty Per Cent Overload.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

[illegible]—October [illegible]—Authorizing G.T.R. to construct siding and spur therefrom for the Shortreed Lumber Co., at Kearney, Ont.

[illegible]—October 22—Authorizing G.T.R. to construct siding for the Canadian Rumley Co., Ltd., Toronto, Ontario.

17838—October 23—Authorizing G.T.P. Branch Lines Co. to construct Prince Albert Branch across highway between Secs. 6 and 7, Tp. 46, R. [illegible], W. [illegible] M., mileage [illegible], Dist. Sask., Sask.

17839—October 23—Authorizing G.T.P. Branch Lines Co. to construct Calgary-Boundary Branch over Diamond Coal Co.'s spur in N.E. ¼ Sec. [illegible], Tp. [illegible], R. [illegible], W. 4 M., by overhead structure.

17840—October 14—Authorizing city of Vancouver, B.C., to construct Hastings St., Pender St., Keefer St., and Harris St., across Vancouver, Victoria and Eastern Ry. & Nav. Co., by means of overhead bridges.

17841—October 1—Approving revised location C.N.O.R. through unsurveyed territory, Dist, Algoma, mileage 280.5 to mileage 290.6.

17842—October 23—Relieving C.P.R. from providing further protection at Main Street crossing, village of Chesterville.

17843—October 24—Authorizing C.P.R. to construct across twelve (12) highways in Manitoba and Saskatchewan, mileage 31.27 to mileage 65.3.

17844—October 24—Authorizing C.L.O. & W. (C.P.R.) to construct bridge across highway at mileage 95.25, Tp. Brighton, Ont.

17845—October 24—Authorizing C.L.O. & W. (C.P.R.) to construct proposed bridge across road between Lots 28 and 29, Con. 2, Tp. Whitby, Co. Ontario, Ont., mileage 164.42, station 1018.35.

17846—October 23—Approving plan of structural work of C.N.R. proposed bridge over C.P.R. Co.'s Secondary Canal "B," in Sec. 9, Tp. 25, R. [illegible], W. 4 M., Alberta.

17847—October 24—Extending, until July 1st, 1913, the time within which the C.P.R. may operate its Manitou Lake Branch from a point on its Pheasant Hills Branch, in Sec. 6, Tp. 40, R. 19, W. 3 M., to a point in Sec. 32, Tp. 43, R. 21, W. 3 M., mileage 0 to mileage 27.8, between Wilkie and Cutknife, Saskatchewan.

17848—October 23—Requiring the Esquimalt & Nanaimo Ry. Co. to appoint and continue a permanent agent at Cowichan, B.C.

17849—October 24—Authorizing C.P.R. to construct third track, south of its present tracks, across tracks of Jacques-Cartier Union Ry. Co., on Lot Cadastral No. [illegible], Parish of Lachine, Co. Jacques Cartier, Que.

17850—October 24—Authorizing G.T.P. Branch Lines Co., temporarily, to carry traffic over its Biggar-Calgary Branch from Biggar to No One Siding, distance of 7.1 miles.

17851—October 24—Authorizing C.P.R. to construct spur for the John Irwin Co., Ltd., Calgary, Alta.

17852—October 25—Authorizing C.P.R. to carry freight, temporarily, on its Lacombe Easterly Branch from Coronation to Consort, a distance of thirty-two miles.

17853—October 24—Authorizing C.P.R. to construct industrial spur for Canadian Milk Products, Ltd., and crossing road allowance between Lots 16 and 17, Con. 15, Tp. Yarmouth, Co. Elgin, Ontario, near Belmont Station.

17854—October 25—Authorizing C.P.R. to cross, for construction purposes only, the tracks of Grand Trunk and Toronto Street Railway Companies, and John Street, city of Toronto, Ont., crossings, when in operation, to be protected by watchman.

17855—October 25—Authorizing C.P.R. to construct subway No. 100.5 at the east end of Coquitlam Yard, on Cascade Subdivision, British Columbia Division, in Province of British Columbia.

17856—October 25—Authorizing C.L.O. & W. (C.P.R.) to construct bridge [illegible], Tp. of Camden, Co. Lennox and Addington, Ont.

17857—October 25—Authorizing G.T.R. to construct siding for J. John[illegible] on Lot [illegible], Tp. [illegible], Co. Simcoe, and Province of Ontario.

[illegible] Authorizing G.T.P. Branch Lines Co. to operate [illegible] over Pheasant Hill[illegible] C.P.R. [illegible], R. [illegible], W. [illegible] M., Dist. Saska[illegible]

17859—October 22—Approving location C.N.O.R. station grounds at [illegible], Tp. [illegible], Ont.

[illegible] Pointe aux Trembles, Que., [illegible] Ry.

[illegible] to construct farm crossing [illegible], R. [illegible], W. [illegible] M.

[illegible] C.N.O.R. to construct across Sault and [illegible] overhead structure.

[illegible] C.P.R. to construct spur for the St. Lawrence Bridge Co., Ltd., crossing main spur and connecting with another spur of G.T.R., on Lot Cadastral, No. 915, Parish Lachine, Co. [illegible]

[illegible] C.L.O. & W. (C.P.R.) to construct [illegible], Co. Durham, Ont.

[illegible] C.L.O. & W. (C.P.R.) to construct [illegible]

[illegible] Order directing [illegible]

[illegible] B.C., [illegible] platform at that point [illegible]

The Canadian Engineer

An Engineering Weekly

THE BROOKLYN GRADE CROSSING COMMISSION.

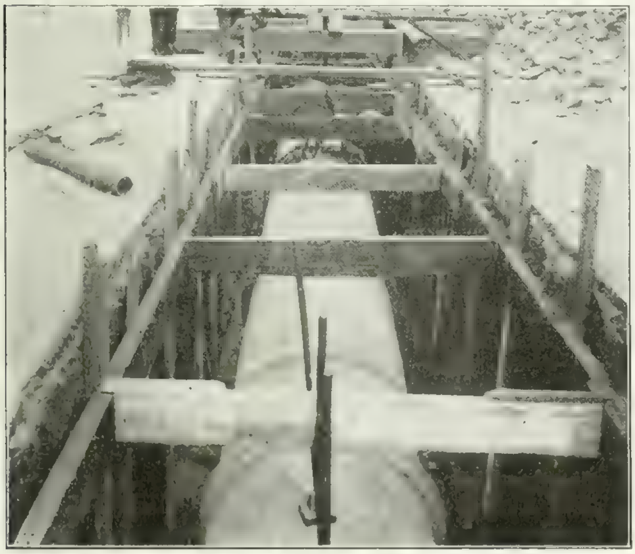
Pipe Raising at East New York, Brooklyn, N.Y.

By WM. C. SAMPLE.

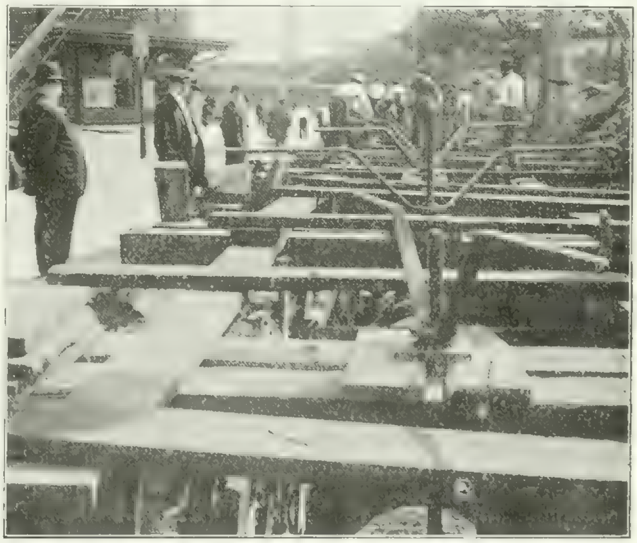
Mr. Sample was in the employ of The Brooklyn Grade Crossing Commission for upwards of five years. For four years of this period he occupied the position of designer and estimator to the Bay Ridge Improvement. Quite recently Mr. Sample was engaged to fill a position at Fort William, Ont., with the Barnett, McQueen Co., Engineers and Contractors, Minneapolis and Fort William, who have the contract for the design and construction of the three million bushel addition to the Canadian Northern Elevator at Fort William.

During the past eight years the Brooklyn Grade Crossing Commission has been engaged upon the largest scheme of grade crossing elimination ever carried out in the United States.

The commission was created by an Act of the New York State Legislature, which became a law on May 9th, 1903, entitled as follows: Chap. 507, an Act to abolish certain grade crossings of highways and railroads in the borough of Brooklyn in the city of New York and county of Kings, and providing for necessary changes in the grades of highways, streets and avenues, and of portions of the railroad and right-of-way of the New York, Brooklyn and Manhattan Beach Railway Company, leased to the Long Island Railroad Company, and of the Brooklyn Union Elevated Railroad Company, leased to the Brooklyn Heights Railroad Company, so as to abolish present, and avoid future crossings at grade, and providing means for the payment for such alterations or changes.



View of Fort Hamilton Main Before Raising.



View Showing Screw Jack in Position, Fort Hamilton Main.

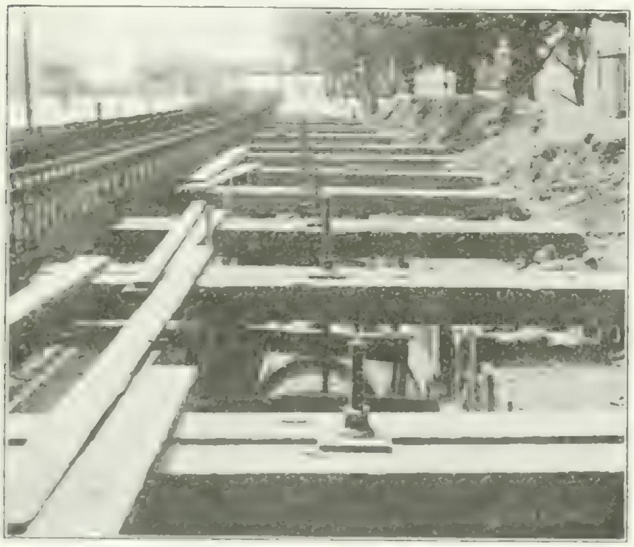
The Act authorized the mayor of the city of New York (Hon. Seth Low) to appoint a commission of five, three of whom should represent the city, one to represent the Long Island Railroad Company, and one to represent the Brooklyn Heights Railroad Company, for the purpose of carrying out the provisions of the Act above referred to.

Changes have from time to time been made in the personnel of the commission, and the membership as at present constituted, is as follows: Frank U. Brooks, president; John S. Griffith, secretary; Edwin C. Swezey, general superintendent, representing the city of New York; Ralph Peters, president of the Long Island Railroad, representing the Long Island Railroad Company; and John L. Wells, representing the Brooklyn Heights Railroad Company.

Under the terms of the original Act of the New York State Legislature, the city of New York was required to pay one-half the cost of the work and this was provisionally fixed at $750,000, subsequently increased by amendment to $1,000,000 for the Brighton Beach improvement (Brooklyn Heights Railroad), and $2,500,000 for the Bay Ridge improvement (Long Island Railroad), with the provision that any additional cost in excess of the joint expense of $5,000,000 should be borne by the railroad company alone, except where additional bridges were built at streets not actually opened or travelled, so as to provide for future crossings. In such cases the cost to the city was to be increased so as to cover one-half of the expense of such additional bridges.

The Brighton Beach improvement is now completed, but the Bay Ridge improvement, although in an advanced stage of construction, will take about twelve months longer to complete. The work already done on this last mentioned improvement embraces the raising and depressing of about twelve miles of double track, the construction of railroad and highway bridges with reinforced concrete floors; plain and reinforced concrete retaining walls and bridge abutments, station buildings, freight and storage yards, new streets, etc. The contract for the final section of the work was recently let for a figure approximating $1,250,000, and when complete will bring the total amount expended on the Bay Ridge improvement to about $8,000,000.

The principal item on this final section of the improvement consists of a four-tube reinforced concrete tunnel, 3,500 feet in length, the building of which, in open cut, through the busy East New York section of Brooklyn, [illegible] which the improvement engineers will be called upon to solve. The tunnel will cut through many of the busiest streets in East New York, and [illegible] etc., have been diverted, and this article is intended to deal [illegible]



The Atlantic Avenue Main.

A large amount of work was necessary before the actual raising of the pipes could be undertaken. Detailed drawings showing the existing elevations and location of the water mains in relation to the proposed tunnel were prepared and submitted to the Brooklyn Department of Water Supply, who have jurisdiction over all mains laid in the borough of Brooklyn. This department in turn drew up a large scale plan, embodying a general scheme of the method to be pursued in the carrying out of the work.

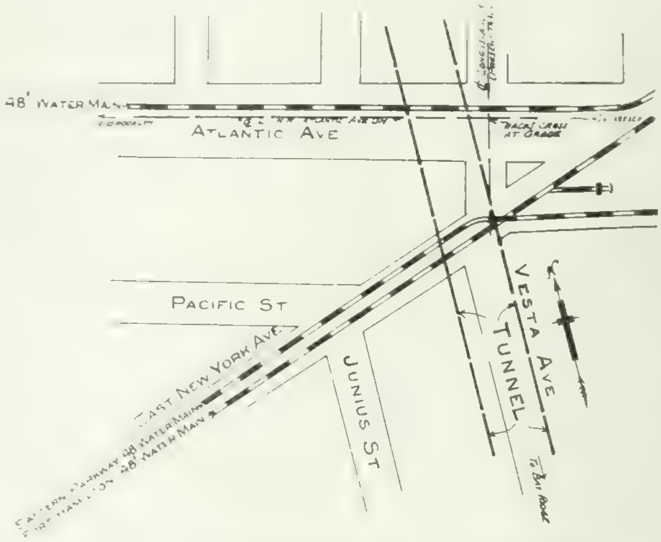


Fig. 1.—Sketch Showing Location of Water Mains.

In Fort Hamilton and the Eastern Parkway water mains, or rather the portions of them which required raising, pass underneath the existing Long Island tracks and provision had to be made for the carrying on of the railroad traffic during the progress of the work. The portion of the Atlantic Avenue main raised did not interfere with the railroad, the end adjoining [illegible] quite close to the tracks.

Table I.

Dia of Pipe in Inches	Break in Inches per Joint	OFFSET IN INCHES FOR Nº OF LENGTHS

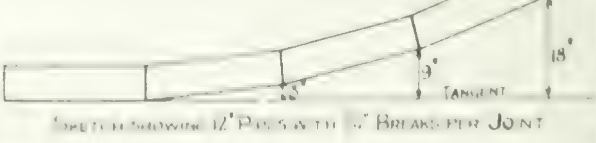
$$\text{Constant for any Break in Joint} = \text{Break in Joint in Inches} \times \frac{144}{\text{Dia of Pipe in Inches}}$$

$$\text{Offset from Tangent at any Pipe Length} = \text{Number of Pipes} \times \left(\frac{\text{Number}+1}{2}\right) \times \text{Constant}$$



Sketch showing 12" Pipes with ¼" Break per Joint

Bents were designed as shown in Fig. 2, and these were placed under the tracks to support them over the excavated pipe trenches. This work was carried out in the early hours of Sunday, when traffic was practically at a standstill.

The plan drawn up by the Brooklyn Department of Water Supply showed that it would be necessary to raise 21 pipes in the Eastern Parkway main; 19 pipes in the Fort William main, and 17 pipes in the Atlantic Avenue main, and the heights to which the mains were to be raised above their original levels were: Eastern Parkway, 2.75 feet (2 ft. 9 in.); Fort William, 2.17 feet (2 ft. 2 in.), and Atlantic Avenue, 2.25 feet (2 ft. 3 in.). To achieve this object the Bay Ridge engineers calculated the break to be given per point from the formula given in Table I.—the formula is self-explanatory. Everything was now in readiness for the contractor, Mr. Frank J. Gallagher, of Brooklyn, to make a start and it was decided that the Eastern Parkway main would be the first to be raised, with the Fort Hamilton and Atlantic Avenue mains to follow in the order mentioned. The methods adopted by the contractor in raising the mains were similar in each case, and it will be necessary, therefore, to detail the work on one of the mains only, as typical of the others. For this purpose the Atlantic Avenue main is selected. It was much the older main of the three, having been laid about forty years ago, and it was anticipated that a great amount of trouble would be met with in raising it. Happily, however, this did not prove to be the case. The pipe joints, when bared, were found to be in excellent condition, and bear eloquent testimony to the splendid manner in which the original contractor had carried out his work. Water main laying is the one branch of contracting that the grafting contractor should avoid. He may be able to pull off some of his old tricks in practically every other grade of contracting, but never with water pipes. Water has a little peculiarity of finding out any weaknesses at the joints.

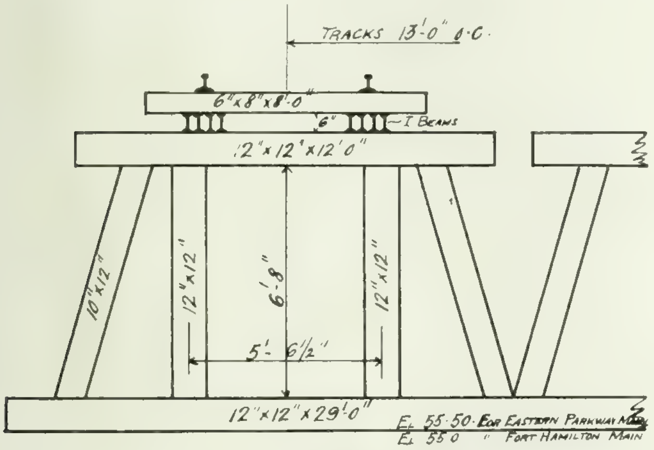


Fig. 2.—Details of Bents.

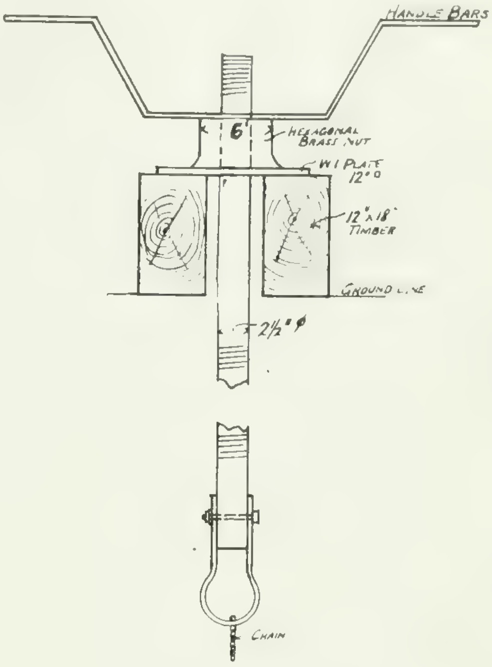

Fig. 3.

In raising the mains twelve screw jacks were used. A sketch of this type of jack is shown in Fig. 3. This sketch, it should be stated, is from memory, as the writer has not any details of it before him, and the dimensions given are therefore only approximate. The jacks are the property of the Brooklyn Department of Water Supply, and were hired from the department by the contractor. It will be noticed that the jack passes through a large brass nut, this in turn rests on two balks of timber placed just sufficiently

apart to allow the jack to pass between them. The balks of timber were given a good bearing on each side of the trench and thus distributed the pressure over a large area. Attached to the jack, as will be seen, was a large powerful hook and this in turn was hooked up with a steel link chain which was passed round the pipes near the bell. Twelve jacks, as already stated, were used, worked by hand power, and these gradually raised the pipes, as shown in Fig. 4, and denoted "First Lift." An engineering corps in charge of Mr. J. P. Patterson, assistant engineer of the Long Island Railroad, was in constant attendance taking elevations of the pipes, and as the first few were brought to grade they were blocked up and the jacks taken to the further end of what might be termed the jack line.

Raising was then commenced as denoted "Second Lift" in Fig. 4, and thus by successive lifts the water main was brought to the desired elevations. The pipes were carefully blocked up, and it speaks well for the manner in which the work was carried out that elevations taken on the pipes many hours after they had been raised and blocked up showed that they had sunk in a few cases only a mere fraction of an inch. The jacks used in the work are capable of raising 25 tons whilst the pipes raised were twelve feet long and weighed about four tons each, or full of water, as they were, nine tons each. The pipes, it should be mentioned, were under a pressure of 40 lbs. to the square inch. A section of the pipe is shown in Fig. 5. As previously stated, the pipe joints on the Atlantic Avenue main were found to be in excellent condition, but naturally the bed blocks were not found in a similar state of excellent preservation, and many of them had to be replaced when the pipes were raised. It should be stated that the contractor had a number of caulkers in constant attendance, and whenever any weakness in the joints became apparent, it was speedily attended to. Fig. 5 shows a section giving the original and new locations of the water main under review, and appended to it is a table giving the original and new elevations, together with elevations taken on the pipes during the progress of the work. A perusal of these will be found interesting and will in part explain the "Lifts" shown in Fig. 4.

The Eastern Parkway main was subject to a pressure of 40 lbs. to the square inch, and the Fort William main to a pressure of 80 lbs. to the square inch. With regard to the Fort William main it should be mentioned that part only of it was raised under full pressure. It is syphoned under the Eastern Parkway main, and owing to an extra bend having to be added to it, the water was turned off [illegible].

The whole of the work was carried out under the direct supervision of Mr. L. V. Morris, the chief engineer of the [illegible]

[illegible]

LIGHT COMPRESSION MEMBERS.

(Concluded from last issue).

Mr. Horton: I am disposed to suggest that the difficulty with the details was that they wrinkled, and have suggested that a thousand tests be made in the laboratory to discover how to lessen the wrinkling.

Chas. K. Mohler: I wish to call attention to some points which may be of interest, in connection with the distortion and partial failure of some trestle columns under conditions where they should not have failed, if the bent, of which they formed a part, had been properly designed. The distortion was made possible on account of the omission of diagonal bracing between the columns. Briefly, the bent was located at an angle in the north approach to a bridge over the Monongahela River at Pittsburg. The columns carried the east end of the riveted pony truss, which made an angle of about 35° or 40° at this point with the main approach. A timber trestle was built at right angles in the opposite direction. Through expansion and contraction, or the tilting of the bents of the timber trestle, or both, the spans, together with the tops of the columns, were carried at right angles to the trestle. The columns were bent fixed at both ends, and as a result both columns were bent in double flexure or reverse curves. The lacing bars in compression were badly buckled. The columns were not over 20 ft. high. There would have been no failure from any strain that comes upon the bent if it had been supplied with the necessary diagonal bracing. The omission of the diagonals was inexcusably bad design. There were many other instances of bad detail in this particular structure, but they do not relate to this discussion.

This simply shows that many times failure of a structure is caused by some of the members having to take care of loads and stresses which they were not designed to carry.

F. G. Vent: Mr. Jensen made a remark about not worrying too much over the proportion of the length to the radius of gyration. I think when you get over 200 you have to begin to look out. A short time ago a certain manufacturer submitted a design for a roof truss, which I had occasion to check. It was what is called a skimp design, and in figuring it over I found that the sections had a large ratio of $\frac{l}{r}$. One of his excuses for this was that we had a structure which was built where the $\frac{l}{r}$ was somewhere around [illegible], built by George S. Morison. In referring to the plans for that truss I found that by taking the section of the compression member and figuring only the outstand[illegible] the $\frac{l}{r}$ to about [illegible], and the design was well proportioned. The de[illegible] was somewhere [illegible] $\frac{l}{r}$ in every member. This shows that if we [illegible] we will sometimes find that the $\frac{l}{r}$ is [illegible] just the outstanding flange we will [illegible] $\frac{l}{r}$ [illegible] low.

Mr. Horton: I understand, Mr. Jensen, that the $\frac{l}{r}$ is of much less significance than is frequently ascribed to it, and the tests of full-sized members certainly show this fact. Tests have been made, up to 175 $\frac{l}{r}$ on large pipe and **H** sections, and the ability to stand loads is not much lessened at that length (about 20% less than the strength at 35 $\frac{l}{r}$). No column of over 120 $\frac{l}{r}$ can be used in Chicago, whereas tests of rolled sections show a loss of only about 16% between 35 $\frac{l}{r}$ and 120 $\frac{l}{r}$. With the straight line formula $16{,}000-70\frac{l}{r}$, to limit the radii length is absurd.

Lewis McDonald: There has been considerable talk about the relation of the radius of gyration to the length, and because some experiments have seemed to show that this did not have the significance which we have usually attributed to it, it seems that some would do away with it altogether in their designs. I do not think that we should forget our early training in this respect and we should still consider the relation of the radius of gyration to the length. But there are other things which enter into the design of a column which perhaps we have overlooked in the past and which recent failures have brought more particularly to our attention, and while we should not omit to take this into consideration, we should give other things, such as wrinkling, thickness of material, etc., their proper consideration. I do not think it is the intention of any one to say that we should design our columns up to 300 or 400 $\frac{l}{r}$. Probably the original formula which was worked out was all right, and so long as we had homogeneous material, that probably would be the only consideration which we would need to give. But in built-up members it certainly is necessary that we consider the shop work and the effect of driving more or less rivets and other things which we have heard discussed.

Mr. Horton: Referring to Mr. Vanderlip's remarks, we can scarcely imagine a boom built of four angles which would not be very satisfactory as regards $\frac{l}{r}$. I am reminded of a boom 100 ft. long, 24 in. square in the centre, built of four 1½ by 1½ by ¼-in. angles, laced on four sides with 1¼ by 1¼ by 3/16-in. angles in 2-ft. panels. This boom was entirely satisfactory as regards $\frac{l}{r}$, but the other question came up as to its sufficiency as a beam. Could it be handled as a beam, that is lifted at the centre or at the ends? Calculations showed that it could. Experiments made later showed that the actual corresponded with the calculated deflections. This is interesting, as a ratio of length to depth of 50 to 1 is an unusual proportion.

J. W. Bradford: It is quite a problem to know just how light we can make many of these struts, but we are called on at times to furnish some which are not so light. I know of instances where we have been called on to make struts 2 ft. or more in width, and laced with angles, which makes a very heavy and costly member. The ordinary strut made with four angles laced makes a very good strut but it runs up in weight, and where the four angles are turned in and laced, the cost of shop work is very great. In many cases the strut made of two channels with lacing between them makes a very light strut and one with which it is very easy to get a good end connection.

Arthur N. Talbot: The compression member is a fruitful topic for discussion, and the remarks made on this topic are interesting and bring out many different views. As the column is used under such diverse conditions, it is not strange that such a variety of views exist. Our knowledge of the action of the column is incomplete, so much so that its properties offer a very promising field for investigation. In fact, one of the great needs in the line of structural engineering lies in experimentation on the action of compression members. However, it should not be lost sight of that a great deal of information on column action is available and that certain things have been established. A reader might gain wrong impressions from some of the statements in the discussion, impressions which the speakers doubtless did not intend to convey. Possibly a few general statements will serve to clear up some ambiguities.

(a) Long columns do fail by flexure, very much as indicated by Euler's analysis. Simple laboratory experiments show this. A very good collection of the results of these tests which have been made on columns may be found in the Proceedings of the American Society of Civil Engineers for December, 1911, pages 1290-98, and these tests bring out very well the effect of flexural action in long columns. If the modulus of elasticity of the column is known, and the section is such that the column will not collapse or distort laterally, the maximum load which will be carried by very long columns may be fairly definitely stated if the end condition of the column is known. For mild steel, long column action may be expected in columns having a length, say, of more than 125 $\frac{l}{r}$ for columns with round ends, and of more than 250 $\frac{l}{r}$ for columns with fixed ends. However, it is known that the stiffness of the built-up column is much less than that of a solid section, as is shown by tests in flexure, and therefore a lower value of the modulus of elasticity must be used in Euler's formula than will obtain for solid material.

(b) What constitutes a round end and what a fixed end, cannot be stated very satisfactorily. It seems evident that a pin-ended connection will offer little end restraint and may be considered to be a round-ended column in one plane. A flat-ended column may act as fixed-ended, especially if it has an enlarged base resting on a firm bearing. Between the extremes of round ends and fixed ends there is a wide range of conditions, and the method of holding the ends, the tightness of the riveting, and the fixedness of the supports are elements which give uncertainty. There is a lack of information on the actual end restraint to be found in building construction.

(c) For very short mild steel columns, of other than solid section, failure is generally by a crinkling or wrinkling action. This action starts at some point where the local stress exceeds the yield point, and this critical load should be considered the strength of the compression member, even though in some forms of section the ultimate load for columns of very short lengths may be such as to give an average stress well beyond the yield point of the material. Just how far this critical load is below the load which would give an average stress equal to the yield point of the material, will depend upon such matters as the imperfection of parts, like crookedness, eccentricity of bearing, eccentricity of rivet bearing, and the movements of the structural elements upon each other. For such short members the strength depends very much upon the form of section and the method of fabrication.

(d) For compression members having a length intermediate between that of the very long column and the very short compression member, the slenderness ratio $\left(\frac{l}{r}\right)$ does affect the strength of the column. Just why this is true is not clear. It is evident that the reasoning about the effect of the length used in the derivation of Rankine's formula is not entirely tenable. It might even be thought that as the column of intermediate length does not deflect laterally to an extent which will explain failure, the strength of a column will remain nearly constant from the very short column to the vicinity of Euler's curve. However, the tests of columns show a gradual reduction in strength with increase in length, though the reduction is of a different character and generally less in amount than that given by Rankine's formula. In fact, tests show that a straight line inclined to the axis represents the results of tests of compression members of intermediate length very well—better than the Rankine formula. Failure in such columns may be by crinkling or wrinkling, the yield point being exceeded at places not necessarily at the centre of the length, and no special bowing or lateral deflection occurring in the amount which would be necessary to explain the failure, such as is seen in the failures of very long columns. In other words, failure seems to be due more to local causes than to general curvature along the whole length as is assumed in most column analyses. As has been indicated, reduction in strength in this intermediate field may be said to be directly proportional to the length of the column, though just why this is has not been determined.

(e) The extent to which length affects the strength, for columns of this intermediate length, seems to depend upon the shape of the section, the thickness of parts, and the method of making up the section, as whether the structural elements are riveted together, as in the case of built-up columns, or whether the piece is an integral rolled section. The tests of rolled **H**-sections made at Watertown arsenal [illegible] may be expressed by the formula $\frac{P}{A}$ = [illegible] $\frac{l}{r}$ for ultimate strength, up to the [illegible] $\frac{l}{r}$ [illegible] $\frac{P}{A}$ = [illegible] $\frac{l}{r}$ for the elastic limit of the columns. The tests of lap welded [illegible] may be expressed by the formula $\frac{P}{A}$ = [illegible] $\frac{l}{r}$ for ultimate strength, the graphs up to the point of $\frac{l}{r}$ [illegible] the tests [illegible] $\frac{l}{r}$ [illegible] strength by $\frac{P}{A}$ = [illegible] $\frac{l}{r}$. These equations [illegible] strength [illegible] of the longest length tested. The formulas for ultimate strength [illegible] [illegible] [illegible] (Bulletin No. 60) made at the University of Illinois are expressed by the equation $\frac{P}{A} = 36,500 - 155\frac{l}{r}$. It is evident that in this form of column, length has a much larger effect than in the two other forms. The general forms of column sections may be expected to have strength equations lying between this equation and the preceding two. An interesting fact brought out in the tests of the Gray columns (see Bulletin No. 56 of the Illinois Engineering Experiment Station) is that at small deformations the effect of length of column is very much less than at the higher deformations, and in this may be found a suggestion bearing upon the explanation of column action. It should also be noted here that in tests of built-up columns the load-deformation diagrams have a considerable curvature even at low loads, while in the tests of the rolled columns the low load-deformation diagram is nearly straight up to the yield point of the columns.

(f) The amount of the effect of the slenderness ratio $\left(\frac{l}{r}\right)$ through this range of intermediate lengths depends also upon the end condition of the column. The equations given in the preceding paragraph are for columns tested with flat ends which acted in the tests as fixed ends. The diagrams giving the results of tests of free-ended columns show a greater slope. Just what explanation best fits the existence of this greater slope, if general flexure is not the only cause of decrease of strength, cannot now be told. It must be understood, however, that end condition does affect the strength reduction for columns of intermediate length, and that a statement of the end condition assumed may well go with the formula.

It may be observed, too, that a single formula for all forms of sections and for different end conditions may not be expected to express the actual column strength.

Some very interesting questions have been raised in the discussion on compression members. One of these is, why not remove the limit of $\frac{l}{r}$. Why was this limit inserted in the ordinance? Possibly because it was felt that there is too much uncertainty in the action of the column beyond the length of 120 $\frac{l}{r}$. Possibly it was done because it was appreciated that the end condition—whether round or fixed—so largely affects the strength of very long columns, and it was not expected that the brief statement in the ordinance could provide for the variations in condition likely to be found in practice. Besides, it has been thought possible by some that in a column formula for homogeneous columns the line which represents the strengths of columns of intermediate length may intersect Euler's curve instead of being tangent to it as commonly assumed.

Enough has been said to justify the remark that more experimental knowledge of column action is needed, for the variety of [illegible] of section, of bearing, of length, and of [illegible]. The view expressed by Mr. Horton, that a large number of laboratory tests are essential to give us an adequate understanding of column strength, has much to support it. The effect of form of section, of thinness of parts, of [illegible], of end condition, of length and slenderness [illegible] different end conditions and different [illegible], of form of [illegible] and its spacing, of lateral supports, of the effect of [illegible] of the effect of the [illegible] with rivets, of the [illegible] Mr. Horton's [illegible]. As Mr. Horton says, "No more mental analysis will ever show us the required relations. Physical tests are required."

And why may not such tests be made? Not all that may be suggested, but a large number along specified lines selected with a view of advancing knowledge on many disputed and unsettled questions. And why should not the Bridge and Structural Section of the Western Society of Engineers take an active part in promoting a movement for such experimental work, in outlining the most profitable lines of research, and in other ways contributing toward the advancement of knowledge in this important matter? Surely a means of co-operation in so promising and fruitful a field may be found.

◆

BRITISH INVESTIGATION OF RAIL CORRUGATION.

The Municipal Tramways Association of Great Britain has been conducting an elaborate study into the causes of rail corrugation and the possible remedies of it, and a report of its committee on this subject was presented at the convention of the association at West Ham, Sept. 25-27. The committee consisted of twenty members, of whom fourteen were railway men and six were outside engineers. The committee has been engaged upon its investigations for a number of years and has been in special activity since February, 1911.

A feature of the work of the committee was a series of extensive experiments to determine the movement of the cars on track and other facts which might have a bearing upon the general subject. Some of these tests were conducted by the committee and others by individual members of the committee. An account follows:

In one experiment a jet of white liquid was discharged from a nozzle fixed at the front end of the truck of a single-truck car, and a jet of red liquid was discharged from a nozzle fixed at the rear end of the truck. A measurement of the records left on the pavement by these jets gave information as to the movement of the truck, wheels and axles relative to the truck. The records thus obtained appeared in the report and their significance was discussed by the committee.

In another experiment a pad of felt to which a supply of white oil-paint was fed was pressed lightly against each rear wheel. In this way a film was left on the track, and it was possible in many cases to produce artificial corrugations in the paint film apparently identical in every respect with actual corrugation marks produced under working conditions. In some cases, however, there were corrugation marks in the paint where there were none in the rail.

In another experiment a single rubber stud was set into each wheel tire and, as it made contact with an ink or paint pad, each revolution of each wheel was marked on the track. On other roads a hard steel sharpened stud to mark the rail was used instead of the rubber stud. The records thus obtained with each wheel of the car were compared to determine the extent of slip and skid of wheels on straight track and curved track, with power and without power etc. Records thus obtained are shown in the report and proved in the opinion of the committee that slip and skid are taking place continually on all wheels under all conditions, even on a car in which an especial effort has been made to have all four wheels brought to the same diameter and where the car is being driven on a straight track. In one test of this kind carried out in Glasgow, where one wheel was 1/16 in. less in circumference than the other three, it was found that at no time, while the car was being driven by its own motor, did any of the wheels cover a distance equal to their circumference, although when the car was being hauled as a trailer the smallest wheel of the four covered the required distance almost exactly. The committee concludes, therefore, that there is always a certain slip going on between the wheels and the rails even under very best of conditions as regards mating of wheels.

In another test two small hard steel studs were placed in the curve of each rail at exactly right angles on straight track or exactly radial on curves. These studs were depressed by the wheel flanges and completed an electric circuit, making a record on a traveling sheet of paper. By this device the position of the axles in regard to the track would be recorded as each car passed the studs. The apparatus for this test was not completed in time for the committee to give results.

Another test was to loosen a section of rail on a curve and one on straight track to ascertain the effect of a loose rail. Another was to remove the lip of a section of rail on straight track and on a curve. Neither of these showed any apparent effect as regards corrugation, except that in Manchester the removal of the lip on the outside rail on a curve seemed to increase the corrugation.

A test made by allowing cars to coast over specified lengths of curved and straight track which was already corrugated was found to reduce the corrugation on the straight track but did not seem to have any definite result on curved track. In another test the gauge of the track in sections of corrugated track was tightened and loosened, in each case ½ in. In the case of the tight gauge the effect was marked, particularly on curves, where the outer rail became more corrugated and the corrugations changed their form, being at right angles to the gauge edge instead of sloping backward from the gauge edge. On the widened section of track the corrugations seemed at first to grow less but afterward became more pronounced.

Another interesting experiment, which was conducted on the lines of the London County Council Tramways, was that of making oblique cuts across the tread of the corrugated rail. These cuts were ⅛ in. wide, 1/16 in. deep and 3 in. pitch, and they sloped at an angle of 60 deg. in the direction of traffic. Two 45-ft. rails were treated in this way, and before they were cut one rail was ground free from all corrugations while the other was left corrugated. The rails were closely watched, but no effect was apparent. In the rail which was ground before being cut the corrugations reappeared after two months, and in the other rail the corrugations became slightly less.

In another test a car was driven along some new track by means of the rear motor alone, and the wheel brakes were applied to the front wheels. Very distinct markings, which bore a decided resemblance to corrugation, were left on the rails.

Tests were also conducted upon the character of the metal at the crests and the hollows of corrugated rails. Strips of metal cut vertically from the tread of the corrugated rail showed in the internal portions of the head an average of twenty-eight points on the scleroscope, while on the surface of the crests the average was thirty-five and at the hollows thirty-three. This indicated that the surface was harder than the body of the rail and that the crests were slightly harder than the hollows. Acid tests on the surface of the corrugated rail also showed that the surface of the crests was harder than the surface of the hollows, but this condition did not exist to a greater depth than ⅛ in.

As the result of its investigations, the committee arrived at the following interim findings:

"Corrugation occurs very widely on systems with electrically self-propelled rolling stock, the construction of which necessitates a relatively low centre of gravity, also on cable systems and to a relatively small extent on steam railways.

"The check or guard is not a necessary factor in the production of corrugation.

"On almost every system it occurs abundantly at places where the break is very seldom applied and is not any more frequent or pronounced at places where the brakes are regularly applied, as at stopping places. It may be concluded that the great bulk of corrugation is not due to any action of the brake.

"The occurrence of corrugation is not dependent on the number of cars which have passed over the rails.

"It is not necessary that the track or the rolling stock or the wheel profiles should be in a worn or defective condition in order to produce corrugation. With all these factors in excellent condition, a car traveling with power under ordinary conditions will readily produce corrugation.

"Corrugation appears on the rails independently of whether the wheels are being actively driven by the motors or not. The committee is of opinion that the explanation of this may be the slip and skid taking place owing to the different diameters of the wheels, which difference largely results from the unequal wear produced by the relative difference in speed of the two motors.

"Corrugation produced by one set of cars may be entirely removed by another set of cars running in place of the first. It may also be caused and removed by the same set of cars under apparently the same conditions.

"The pitch of corrugation is independent of the speed of the cars producing the same.

"Corrugation does not exist on tramway rails as received from the rolling mills.

"Corrugation has been produced by every known type of electric car, and the pitch and characteristics are independent of the type of such car producing the corrugation.

"It is suggested that the brightness of the crests of corrugation, as compared with the comparative dullness of the hollows, is due to a purely rolling action under increased pressure over the crests, and that other portions of the rail are not subjected to a purely rolling motion but to the action of slipping or skidding, alternating with the roll- [illegible]

Suggested Measures for the Mitigation of Corrugation.—"The committee considers that its investigations have produced ample evidence that the force or forces responsible for the reaction between the wheels and rails which results in rail corrugation are external to the rail. It is realized, however, that while rails rolled to any known specification [illegible]

"The committee, therefore, [illegible] a rail steel of such physical character as to resist the ten- [illegible]

"From evidence collected, coupled with the actual ex- [illegible]

[illegible] found that a rail steel which has merely an increased carbon content is not sufficiently durable for this purpose; it is necessary that the rail should be both hard and tough.

"The steel for this purpose should be relatively high in manganese, carbon and silicon, and should be capable of passing the following physical tests: Tensile test, not less than 50 tons per square inch; elongation, 12 per cent. on 2 in. tup test, with rails similar to B. S. section, No. 4, 1 ton falling 15-ft. deflection not more than 1½ in. Brinnel impression test, 50 tons on ball 19-mm. diameter, impression not to exceed 3.5 mm. Curving test, rails to withstand a test curve of 20-ft. radius, either inward or outward, without fracture."

Further Experiments Recommended and Information Required.—The committee suggests further experiments and additional information as follows:

Tests to be made of the amount and period of torsion on the axles of cars.

Tests to be made of the amount and period of the torsion in the wheel.

The vibration on the rail and foundations to be analyzed.

Continue Experiment No. 4, already described. In this it is proposed to place two small steel studs in the groove of each rail exactly at right angles on the straight or radially on a curve. These are depressed by the wheel flanges and each one makes a separate record electrically on a revolving sheet of paper, thus establishing the relative position of the axles with regard to the track. The speed will also be recorded on each sheet.

Tests to be made of the relative speeds of the two motors on a car and the manner in which any difference is compensated for or adjusted under service conditions.

The effect of altering the centre of gravity of the car to be investigated.

Further experiments to be made on the lines of the Leeds and Glasgow tests with retarded wheels.

Records to be kept of the profiles and diameters of successive sets of worn wheels on a car in relation to the position of the two motors on that car.

Information to be obtained as to what effect the springs of the car have on the production of corrugation.

That the advisability of acquiring a complete set of instruments which will record all car movements simultaneously be considered. Such apparatus could be passed on from one system to another. The records could be readily compared and they could be all obtained by one operator.

In view of the considerable use now being made of micro-photography in the investigation of the minute physical structure of metals, the committee advises that the fullest advantage be taken of this science in the further investigation of the corrugation phenomena.

The report contains as an appendix a bibliography of the subject and also a large number of charts and halftone illustrations showing the results of the tests conducted.

WEIGHT OF CONCRETE.

The average weight of concrete per cubic foot when [illegible] into beams for flexure tests, and into cubes and cylinders for compression tests, is given by the U. S. Bureau of Standards as follows:

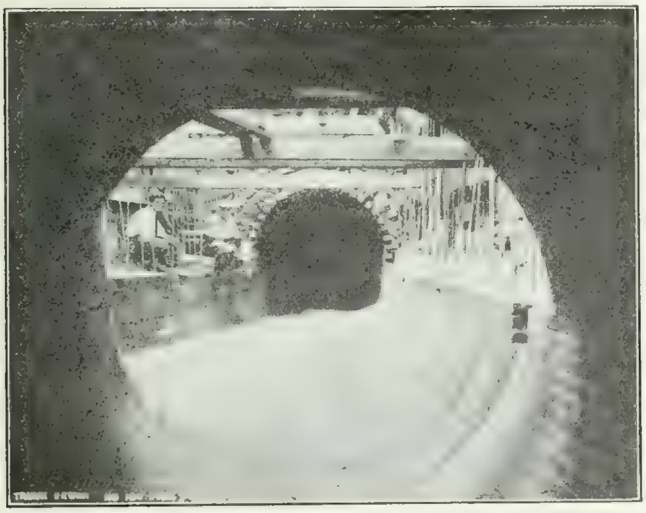
Kind of concrete.	Beams lbs.	Cylinders lbs.	Cubes lbs.
Granite concrete	148	148.6	[illegible]
Limestone concrete	[illegible]	[illegible]	[illegible]
Gravel concrete	144.1	144.8	144
Cinder concrete	[illegible]	[illegible]	118.1

MAIN DRAINAGE SYSTEM OF THE CITY OF TORONTO.

In the issue of October 12th, 1911, of *The Canadian Engineer* we published an article dealing with the main drainage system of Toronto. The annual report of the city engineer of Toronto, for 1911, has just been published and we herewith present an abstract of the report of Mr. A. B. Garrow, assistant engineer, in charge of main drainage works.

High Level Interceptor.—That portion of the high level interceptor, for the construction of which contracts have been let, and which is now all but complete, lies between the Garrison Creek on the west and the sewage disposal works on the east, and might be termed the high level interceptor proper. The high level extension, which is at present being designed, is the continuation of the above sewer westerly to Springhurst Avenue, with a possible further extension to Roncesvalles Avenue.

The past year having, as has been noted, been one of gratifying results, has also witnessed the first, and what is hoped will be the only, misfortune in connection with the construction of the system, namely, the failure of that portion of Section No. 2, located on the east bank of the Don River. This is a circular section, 8 feet 9 inches in diameter, built of reinforced concrete and supported on concrete piers, the construction of which was commenced in September, 1910. For a distance of 300 feet, between the east end of the Don syphon and the old bank of the Don River, the sewage had to be constructed on a filled-in portion of the river bed. The shallow excavation—8 feet at the most—showed a fairly good clay, which, it was estimated, would sustain the weight of the piers upon which the sewer was to be built, and the construction was carried on accordingly. A considerable portion of the invert had already been constructed before it was noticed that the whole 300 feet of sewer was sinking. Observation showed that all the ground in the immediate vicinity was undergoing a similar charge in elevation, and it was realized that any attempt to prevent the sinking of the sewer would have to be postponed till the stability of the ground was restored, and in the meantime the construction was proceeded with. After a study of the conditions it was determined that this peculiar occurrence was due to a combination of circumstances, namely, the placing of the approach of the Wilton Avenue bridge simultaneously with the construction of the Don syphon across the river. The enormous pressure exerted by the former was forcing the soft underlying ground to seek an outlet into the syphon trench, with the result that the surface layer was forced to settle.



Bellmouth.
High Level Interceptor, Section No. 6—Garrison Creek,

The first crack appeared in the invert of the sewer, about midway between the west end and the bank. This quickly widened, and with the appearance of others, destroyed the continuity of the work. The back filling, which was proceeded with, increased the settlement that already had occurred, which resulted finally in a maximum of three feet.

Reconstruction was commenced on August 15th, 1911, and the work put into the hands of the J. H. McKnight Construction Co., who were the original contractors for the section. It was decided to leave in place and underpin a 100-foot section upon which the maximum settlement was 16 inches, and to tear out and reconstruct the remaining 200 feet. Piles were driven close to the interceptor on both sides at 4-foot centres, the centres of the two piles of each bent being 12 feet 9 inches apart. The process of underpinning was to cut off the piles 22 inches below the bottom of the sewer and on them to construct a concrete cradle, reinforced at the bottom with 5, 1-in. diameter, round rods. This cradle was 18 inches wide, and extended up to the springing-line of the sewer. When the concrete had set, the forms were removed and the backfilling replaced, great care being exercised with the latter. The task of tearing out the remaining 200 feet of the sewer was a laborious one, due principally to the presence of the steel reinforcement, which consisted of ⅝-inch square rods. Trouble was also occasioned by the proximity of the approach to the Wilton Avenue bridge on the north side of the excavation, which the rain had made very soft, and for the protection of which a row of anchor-piles had to be driven. When the old concrete and brick invert had been removed down to grade a third pile was added at the centre of each bent, and all were cut off 13 inches below the bottom of the new work. These were capped with a concrete beam 15 inches by 18 inches, reinforced with 5 ⅞-inch diameter round rods. In this instance the invert up to the springing-line and cradle were poured together, and vertical dowels were left protruding at the haunch for bonding the arch. The single ring of brick on the invert was omitted in order to simplify the construction. The new work was set to the original grade and connection made with the under-pinned section (the grade of which was not corrected) in one 25-foot length. The concrete work was completed on December 27th, and after a sufficient interval the backfilling was proceeded with.

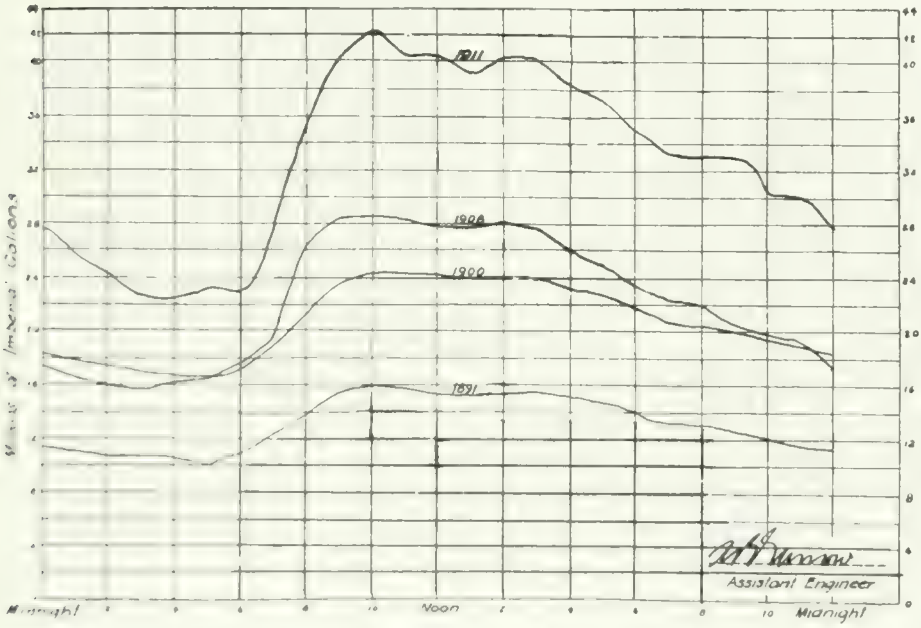
The work necessitated, approximately, the following quantities:

Excavation	1,220 cub.. yds.	
Piles	10,700 lin. feet.	
Concrete, 1, 2, 4	1,210 cub. yds.	(tearing out and replacing)
" "	200 "	(placing only)
Steel	16.75 tons.	

and the total cost, including contractors' 15 per cent., amounted to $14,712.07.

The Rosedale Creek connection, comprising Sections Nos. 14 and 15, has been designed and the contract for the construction of a portion of it awarded this year. The point of interception is located about 3,000 feet west of the Don River, on the Rosedale Ravine Drive, and the pipe required to connect it with the high level interceptor at the corner of River and Mark Streets is 6,600 feet long. It is divided into two sections for the reason that the upper length of 5,700 feet (Section No. 15) is to be in the form of an inverted syphon, for the construction of which 42-inch reinforced concrete pressure pipe are to be used, and the lower 900 feet (Section No. 14) is to be a 3-ft. x 4-ft. 6-in. egg-shape brick gravity sewer. The contract for the pipe for Section No. 15 was awarded this year, and all the pipe manufactured and delivered, although a number have still to be accepted subject to test. The contract for Section No. 14 was also awarded this year, and it is expected that construction will be commenced within a month.

A departure was made in designing the pipe to be laid on curves for the syphon. Since the operation of the syphon would practically depend on the tightness of the joints between the pipes, a special bend was made to be used at the beginning and end of each curve. The standard bend for the curve is made from the straight pipe by depressing one side of the top plate of the mould a sufficient distance to compensate for the difference in distance of the two walls of the pipe from the centre of the curve. To form a true curve with tight joints it will be seen, however, that in making the pipe for the beginning and end of the curve the mould should be depressed only half the distance used on the standard bend. In this way every bend on the curve makes a tight joint with its neighbor, and, with the use of [illegible] in addition, a [illegible] watertight job is [illegible]ted.



Intensity of the Dry Weather Flow. Imperial Gallons per Day for the Years 1891, 1900, 1908, 1911.

Low Level Interceptor.—Very satisfactory progress has been made on the construction of the low level interceptor. Apart from making the plans for Sections Nos. 1, 2 and 3, the entire sewer has been designed, contracts on all the sections awarded, and 16,000 lineal feet, or two-thirds of the total length, constructed within the year. At the present rate of progress it is [illegible] the middle of next year.

The first four sections, reaching from [illegible] Street to Parliament Street, on Front Street, are constructed of brick, [illegible] diameter [illegible] brick sewer. [illegible] the Don section. [illegible] concrete pipe [illegible] the Don River [illegible] pipe which are connected to the interceptor on both sides of the [illegible] is regulated.

Of the brick sections, three were awarded to the Godson Contracting Co., and the fourth, awarded first to the city engineer, was taken over by Messrs. Donnelly & Graham. The work was carried on in tunnel on account of its central location, and the material encountered was blue clay of much the same quality as that found on the line of the high level interceptor, although in some places it was encumbered with fairly large boulders. In one place, between Simcoe and Bathurst Streets, shale and rock outcropped on the invert, reaching a maximum depth of two feet and extending over a length of 500 feet. This reduced the daily progress in each heading from 8 to 4½ lineal feet, and seriously retarded the progress of the section, which had, during one week, averaged over 50 lineal feet a day.

The 5-ft. diameter section and one of the three 5-ft. 6-in. diameter sections were obtained by Messrs. Lehmann, Nicholson & Jerou, and the remaining two 5-ft. 6-in. diameter sections by the J. H. McKnight Construction Co. The former contractor employed a Potter machine on each section. These did not prove very satisfactory, in that they necessitated twice handling the surplus material removed from the trench, were unwieldy on the curves and made pipe handling difficult. A progress of 150 lineal feet a week was the maximum reached by either of these machines. The two clam-shell derricks used by the J. H. McKnight Construction Co., however, proved more suited to the work. One move of the machine of 36 feet representing 200 cubic yards, could be excavated in one day. The pipe-laying, which was done by the same machine, handicapped the work, however, and a progress of 188 lineal feet per week was the maximum obtained.

The contract for the construction of the Don syphon was awarded to Messrs. Miller, Cumming & Robertson. The method proposed by them is to construct the two chambers in the dry, setting the exit and entry pipes in each case, and to connect these across the bed of the river in the wet.

Some important changes have been made in the interception of certain sewers in the west end of the city, which have resulted in a considerable saving in the cost of construction, and an annual saving in the cost of pumping, by reducing the amount of sewage entering the low level interceptor.

The only sewage reaching the Garrison Creek sewer below the high level interceptor is that from King Street on the west, Niagara Street between Defoe and Wellington Streets, Walnut Street and Wellington Street between Walnut and Tecumseth Streets. The flow of sanitary sewage coming from the last three sewers is very small, and its presence in the Bay will create no nuisance until some means have been devised to handle it. By turning the smaller sewers and taking the King Street sewer into the high level extension, it is no longer necessary for the low level interceptor to intercept the Garrison Creek sewer, and a [illegible] at the corner of Bathurst and Front Streets. This plan has been adopted and has resulted in a reduction in the flow entering the low level interceptor of [illegible] gallons per day, and saving the construction of 2,450 lineal feet of sewer, the contract price of which was $13.10 per foot. A further reduction in the amount of sewage reaching the low level interceptor has been accomplished by, where possible, moving the points of interception of the existing sewers along the line of the high level interceptor as far south as the difference in elevation between the existing sewers and the interceptor will permit. In this way it has been found feasible, in the case of Bathurst Street, Spadina Avenue and Peter Street, to move the point of interception from Adelaide Street south to King Street. The total reduction in the amount of sewage reaching the low level sewer due to these two changes amounts to 1,400,000 gallons per day.

The Sewage Disposal Works.—The same expediency exhibited in the construction of the trunk sewers during the year has been evidenced in the construction of, and the ultimate completion of, the sedimentation tanks. Of the total 24 units, 16 have been completed this year, the cast iron and timber penstocks are in place, and the whole has been back-filled and graded. The storm overflow from the tanks, for which plans were made, tenders received and the contract awarded during the year, has been constructed. This consists of a line of 5-foot concrete pipe (of the same design as those laid for the outfall sewer) laid on pile bents and extending south from the southwest corner of the tanks for a distance of 318 feet to Ashbridge's Bay.

Revised Design of Sewer

High Level Interceptor. Original and Revised Design of Reinforced Concrete Section.

The substructure of the pumping station, with the exception of the sludge well, was commenced and completed this year. This work was carried on by the department and was completed in time to allow the contractors for the superstructure to get well under way before the cold weather set in. This latter work is being carried on under the supervision of the city architect, and the brick work is already practically complete.

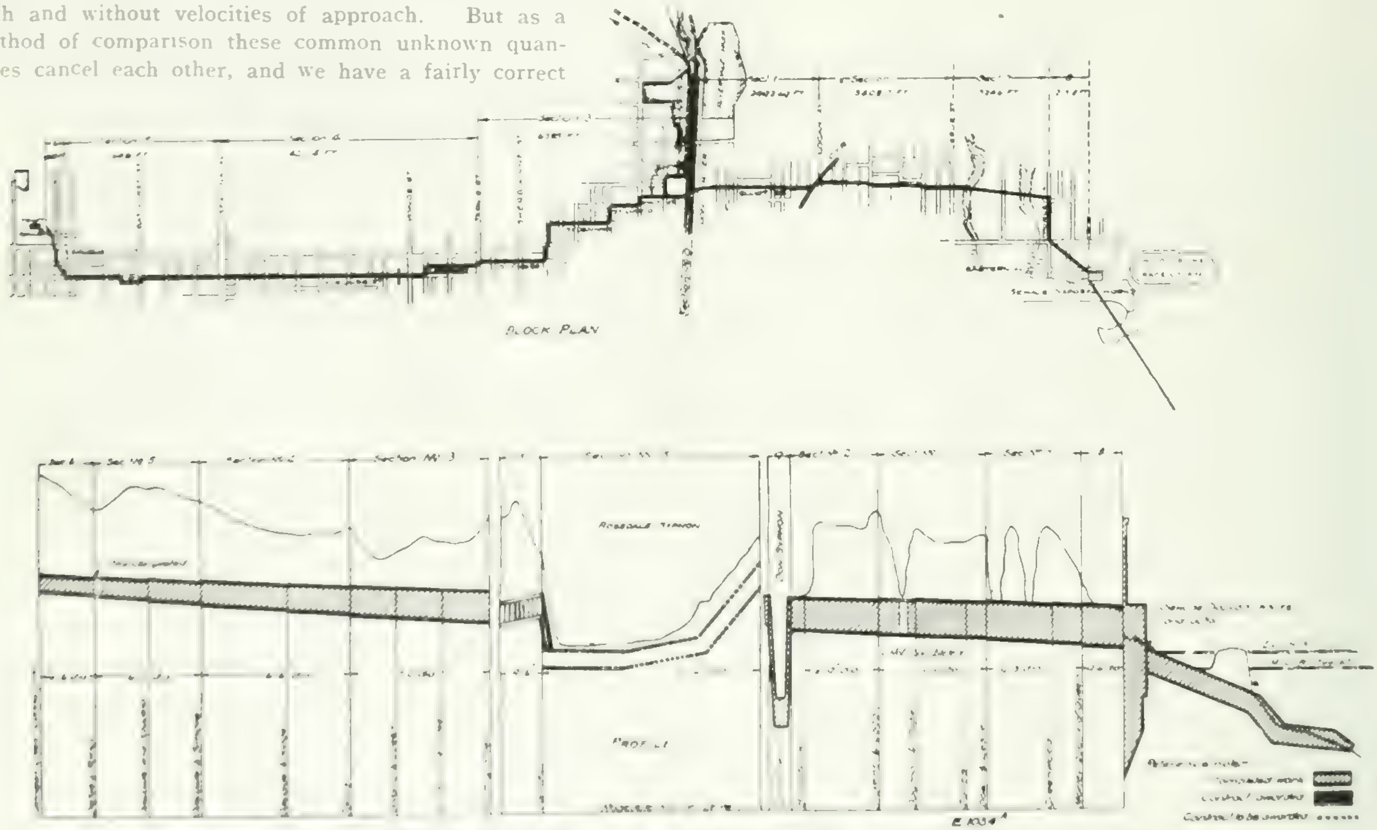
The four high level venturi meters connecting the pumping station with the tanks have been constructed this year. They consist of concrete barrels 38 feet long, 56 inches diameter at the entry and 28 inches in diameter at the throat, substituted at the above two points by iron castings which were manufactured by the Builders' Iron Foundry. Plans were made and manufacture all but completed of the screening and elevating machinery also. It is expected that this apparatus will be in hand early in the next year, when its erection will be carried on. The contract for the supply of cranes, made in 1910, has been revised, and the cranes have been manufactured and delivered. The contract for pumps and electrical equipment suffered some delay owing to the fact that motors called for were unsuited to the current provided by the Hydro-Electric System, which is to supply the power for their operation, and tenders were accordingly cancelled. The manufacture of the pumps has, however, been proceeded with, and will be complete well on time. The revised specification for the motors is under way, and it is hoped tenders will be received early in the new year.

Provision for disposing of the sludge has been under consideration and the method advised in the preliminary report of employing it with the addition of refuse for filling the low-lying ground in the vicinity of the work, partially adopted. It is proposed to sheet pile the south, and portions of the east and west boundaries of the sewage disposal works site, which extend some 300 feet into Ashbridge's Bay, thus providing sufficient space for at least two years' sludge.

Storm Overflow Sewers.—Work on a system of storm overflow sewers was authorized, under By-law No. 5628, which was passed early in the year, providing for an expenditure of $800,000. The work was put in the hands of this department, and the preliminary estimates and surveys were commenced forthwith. Much time was spent in collecting data regarding the locality of floodings throughout the city, the intensity and duration of storms, and other information necessary for planning an efficient system of relief sewers. By September the 6th (on which date the work was handed over to the sewer department), considerable progress had been made, including the construction of 100 lineal feet of Wilton Section No. 1, from the Don to Yonge Street, the completion of the preliminary work on Wilton Section No. 2, and a portion of the preliminary work on the Sorauren, Manchester, and St. Clair relief sewers.

Gauging the Sewers.—Almost the first move in the design of the main drainage system was the gauging of the flow in the existing sewers, which was done in the fall of 1908. In order to check the increase in the flow during the past three years, and to get an idea of what might be expected when the tanks were thrown into operation, it was demed advisable to undertake a second gauging, and this was accordingly commenced in October of this year. The results are, of course, only approximate, due partly to the more or less rough construction of the apparatus employed, and also to the fact that the formula used in the calculation is an approximation between those for flow over weirs with and without velocities of approach. But as a method of comparison these common unknown quantities cancel each other, and we have a fairly correct idea of the increase in flow corresponding to the increase in population.

[illegible]



Progress Profile of the High Level Interceptor, Main Drainage Works, Toronto.

GARBAGE DISPOSAL IN HALIFAX.

The sanitary disposal of the garbage of the city of Halifax is the subject of part of the annual report of City Engineer F. W. Doane, from which we have abstracted the following:

The method of disposition in vogue up to the present is to gather all garbage which would create a nuisance and be a menace to health at the individual residences and haul it to one spot where it is dumped, as a rule, the garbage is dumped at the Exhibition Grounds, but for a month during the exhibition, we are obliged to dump it wherever we can find a hollow in which we can place the material without serious objection from property owners residing in the neighborhood.

The number of places in which the garbage can be deposited is very limited. The hollow at the Exhibition Grounds is rapidly becoming smaller and within a very short time,, will be filled up entirely. If the city does not take steps in the near future to provide for some other place or method of disposal, we shall be forced to deposit it on city property where it will be most offensive and a serious menace to the health of the community.

The disposal of garbage and refuse in a manner conforming to sanitary law, is becoming a matter of vital importance and should receive the immediate attention which so important a matter in the welfare of the city deserves. It is most essential that adequate means be provided for the sanitary disposal of all decomposing refuse, including dead animals and night soil. Sanitary authorities agree that the complete destruction of garbage or a complete change in its characteristics is the only solution that will satisfy sanitary requirements.

A visit to a garbage dump will show it to be a breeding place for flies and rats, and offensive and unwholesome odors are carried from it by the wind for long distances. Flies from such places cannot fail to carry disease into any residence they may enter. The danger to public health is further increased by the sorting over of the garbage by men and women who find articles which they consider of value. The fact that these articles have been in contact for hours, perhaps days, with the garbage, together with the fact that the articles are not likely to be free from filth themselves, emphasizes the risk of conveying these cullings back to the city as carriers of dirt and disease germs.

There are only three methods of disposal which give any measure of efficiency: Dumping at sea; the reduction method, and incineration.

Dumping at sea is not only fully as expensive as burning, but where practiced, is found to be very objectionable even when the garbage is carried twenty miles out to sea, and is being abandoned by all progressive cities where it has been in use.

The reduction method, which consists of passing the garbage only, through a digestive process and taking out its oils and grease, is not popular for the following reasons, namely, that it is expensive to install, it is practically impossible to carry on the process without causing a nuisance by offensive odors, it deals only with the garbage and some other means must be provided for disposing of the remaining rubbish and refuse.

In the cremation method, two systems are followed, one the low temperature furnace, and two, the high temperature furnace.

In the low temperature furnace, the heat is not sufficient to completely destroy all the organic matter in the mass, and noxious, unburnt gases are produceed. In the attempt to overcome this difficulty, coal or other fuel is burned. While the first cost is lower, the annual cost is about the same as in the high temperature furnace.

The city has authority now to borrow $12,000 to install a crematory, but that would not be sufficient even to install a low temperature furnace. The most satisfactory and up-to-date furnace is the high temperature incinerator. It is generally arranged in the modern plants so that the heat produced may be utilized for steam raising and consequently, power can be obtained for the operation of machinery. The operation is carried on without offence from odors, smoke, dust, or noxious fumes and the plant can be located in the neighborhood of residences. Such a plant is in operation in the city of Westmount, Quebec. With Alderman Martin, your engineer inspected that plant in September last.

A careful study has been made of the latest practice and the incinerator at Westmount seems to be the most up-to-date. They raise steam in water tube boilers with the heat produced by the burning of the garbage. They use no fuel in the furnace except the garbage itself and the surplus power obtained is used to assist the operation of an electric lighting plant. In Halifax, the power produced could be used for lighting, running the stone and clinker crusher and for similar purposes.

It is probable that the installation of such a plant as that Westmount with a capacity of fifty tons in twenty-four hours, would cost $40,000, but the time is near when the city must grapple with this problem, and I would respectfully recommend that early action be taken to obtain plans, specifications and tenders for the installation of a modern garbage incinerator so that the necessary legislation may be obtained and some more sanitary method of disposal provided by the time the hollow at the Exhibition Grounds is filled.

Improvements in the method of street sprinkling and street cleaning are almost solely a question of cost. It means an increase of the annual appropriation of not a few dollars only, but thousands, to enable the Works Department to do this work as the Civic Improvement League desires. The sprinkling in the suburbs of the city is done by contract, with the exception of one district which is covered by a Works Department cart. These carts are covering as many miles of street as it is possible to water in half a day, but horses could not stand the work if the length of the district were increased. The remainder of the city, including all the business and oldest residential districts, is covered by fire department carts. The Board of Fire Commissioners limit the distance which the horses are allowed to go from the fire stations and consequently the length of streets sprinkled by the fire carts cannot be increased. The appropriation for this work is limited, therefore the number of hired teams employed cannot be increased.

Street cleaning at night has been suggested as an improvement on the present system. Outside the paved streets, the work could not be as well done in the night; it would cost more and no good, practical reason has been suggested for doing it at night instead of in the day time. Under certain conditions, it is better to clean paved streets at night instead of in the day time, but such conditions do not exist in Halifax. In large cities, it is a practical impossibility to clean thoroughly, paved streets on which there is heavy traffic, during the day time. It is the practice on such streets to remove the dirt roughly during the day and give the streets a thorough cleaning at night, when there is no traffic on them. The night cleaning is adopted, however, from necessity, and not from choice. In such streets the roadway is dirty all day long. In Halifax, the paved streets are kept clean during the day, which is the time when cleanliness is needed, and not at night.

The cleaning of the unpaved streets is quite as unsatisfactory to the Works Department as to the citizens who are complaining. If there were money enough in the appropriation to clean them twice or more, the streets should be cleaned in a short time, at the first of the season, but as there is money enough to clean the unpaved streets once only, it becomes necessary to leave those streets on which there are no permanent gutters, until June or later, because if they are cleaned earlier the grass grows in the gutters after the cleaning is done and remains there until the next year, which makes these streets very unsightly. It is, therefore, the practice to do the cleaning after the grass has grown or begun to grow, so that the streets, when cleaned once, may be more sightly during the tourist season.

On those streets which are most important, and which are cleaned first, the work is begun as soon as the season opens. This year the season was very late and no allowance is made by the critics for this obstacle to early cleaning. The cleaning cannot be pushed until the frost is out of the dirt. The sun is shining brightly in some years in the month of February, but the frost is in the dirt for weeks after that date. Cleaning has been commenced as early as the 11th of March, whilst this year it did not begin until late in April.

If the money were provided, the unpaved streets would be kept as satisfactory to the public as the paved streets, but $1,000 a mile is expended annually in cleaning the paved streets, while the expenditure in cleaning the unpaved streets is only $74.00 a mile. It is impossible to organize and maintain a $1,000 service with $74.00.

◆

RIDING ON PILOTS OF RAILWAY ENGINES.

The Board of Railway Commisisoners have issued an order following a tabulation of accidents resulting from persons riding on railway engine pilots, according to this order the practice must be discontinued in all classes except switching.

COST OF DRIVING STEEL SHEET PILING.

Very little data is available as to the cost of driving steel sheet piling. The Carnegie Steel Company has recently issued a little booklet entitled "Steel Sheet Piling." In this is listed a number of steel sheet piling jobs for which the cost of driving has been obtained by the company. The following figures are abstracted from the booklet:

The cost of driving steel sheet piling depends on a number of very variable factors, such as the kind of piling, the character and size of the structure, the character of the material to be encountered, depth of penetration, type of pile driver, kind and weight of hammer, experience of the crew, etc. The items which make up the driving expense are likewise variable, such as the pro rata cost of the pile driving equipment, including the driver, hammer, hoisting engine, tackle, etc., with proper allowance for depreciation, etc., if owned by the contractor, or its rental and maintenance cost if leased for the occasion; the daily expense in operation for labor, superintendence, etc.; cost of handling piles from the siding or boat to the driver, the cost of fuel, water, oil, waste, etc.; the cost of insurance on equipment, labor and material, etc.

The sum total expense for pile driving crew and regular equipment does not vary very greatly and may usually be put down at $50.00 a day or somewhat less, but this is complicated by the introduction of steam hammers which can be used suspended from derrick booms and for that class of work which does not need a power hammer. In view of these variable factors in driving, cost figures must, in the nature of the case, be only approximate. Such figures, however, may be of some service in estimating the probable cost of complete installations, and we, therefore, append from our records Table I., which gives a selection of the costs of driving various quantities and kinds of piling to different depths of penetration on jobs of the ordinary size and character.

The actual cost of driving 19,654 lineal feet of 12-inch 40-pound United States steel sheet piling (413 tons) in one installation per day of ten hours, was as follows:

1 foreman, per day	$ 5.00
1 engineer, per day	4.00
1 fireman, per day	3.00
6 workmen, per day	10.50
Cost of maintenance and operation	7.00
Total cost of driving crew per day	$ 35.50
Total cost of crew for 21 days	$745.50
Handling and incidental expenses	60.00
Total for job	$805.50
Total cost per foot of penetration	4.1 cents
Total cost per ton	$ 1.95

Piling driven in lengths of from 40 to 60 feet through sand and clay.

THE USE OF FUEL OIL ON THE BRITISH COLUMBIA COAST.

The use of fuel oil on the British Columbia Coast has many advantages over the use of coal. The quantity required to perform the same service is less both in weight and the space occupied, with a proportionate decrease in fuel bills. On the larger boats, the reduction in firemen and trimmers by its use has been as 67 per cent., with the consequent lowering in pay-roll and the cost of subsistence. Such expenses as renewing of grate-bars, stoke-hold floor plates, slice-bars, rakes, etc., are done away with.

Owing to the uniform temperature of the fires, boiler repairs have disappeared. With the use of fuel oil there is no constant opening of furnace doors for firing up, no cleaning of fires, with the consequent inrush of cold air, and the resulting lowering of temperature, which has a serious effect on joints and rivets because of contraction. The experience on one of the large boats running out of Vancouver in this respect is that one boiler in a battery of six was constantly under repair when coal was in use. Since oil has been in use there have been no repairs necessary.

Because of the absence of smoke, cinders and coal dust, oil-burning ships are not only cleaner, but the supplies required for scrubbing and painting are much less. There are no dirty bilges and no corrosion to the bottom boiler plates as a result of absence of ashes.

In point of efficiency the advantages are quite as marked. The calorific values of oil far exceeds that of coal, after deducting the percentage of moisture and ash from coal, the latter from experience being found to run as high as 20 to 25 per cent. The average run of coal will be found to represent 7,000 to 9,500 B.T.U., whereas oil will give as high as 18,500 B.T.U. Owing to incomplete combustion when firing with coal the stack temperatures are very high; with oil, combustion is practically complete, and stack temperatures of 400 degrees to 450 degrees are obtainable. In the case of one large coast steamer the reduction in stack temperature was 950 degrees; the temperature with coal being 1,400 degrees, with oil 450 degrees.

With fuel oil there is perfect control of the fire. When the engines are stopped fires may be completely extinguished, if desired, in the course of a minute. There is no lost time in filling the coal bunkers. The oil tanks can be filled in several hours, fuel enough being taken on to last in some cases twice as long as when using coal.

The efficiency of the plant, and, to a large extent the economy to be obtained, depends on the system of burners adopted. As is well known, there are three methods of atomizing fuel oil employed, viz., by air, by steam, or by mechanical process. The first entails considerable initial expense for compressors, etc., and the cost of operation. The second, while not so costly to install, uses a large amount of live steam, which is unreclaimed, and a consequent drain on the fresh water supply. In addition, the roaring of the burners is disagreeable and a nuisance. The third, or mechanical system, consists of heating the oil to a high temperature and putting it under pressure, from which, when escaping at the burner, it bursts into a vapor and readily ignites.

A large number of vessels, also a number of stationary plants, have been equipped with the mechanical system. Its adoption as being the cheapest to operate and most efficient, was only after careful consideration of the various systems. It is practically noiseless, and consists of a pump, heater and burner. In practice, two pumps and two heaters are fitted, so that in case of a breakdown or overflow there will always be one pump and one heater in reserve. The burners are very simple as to design, and are arranged for changing or cleaning. A burner can be taken out and changed in five seconds, and has various sized tips, which can be used as required, for increasing or diminishing the consumption.

With regard to the supply of fuel oil on the British Columbia coast, there are no present indications of failure. It was reported about the beginning of the year that there was in storage in California alone a quantity sufficient to take care of the world's consumption for seven months. The California and Texas oil fields are by no means exhausted; new wells are constantly being sunk and from indications in Alaska, Alberta and South America other fields will be developed. Notwithstanding, therefore, the immense increase in consumption, the supply promises to be adequate. Two large companies now have storage tanks in Vancouver, and one of these companies will shortly have a storage tank in Victoria. These companies are each prepared to make term contracts for the supply of oil fuel in large quantities.

◆

SUPERVISION OF SEWAGE WORKS.

The proper disposal of sewage is daily becoming a more important factor in the preservation of the health of populous communities. The customary methods of disposal by discharge into flowing streams and large bodies of water as the population increases must often be changed and some method of sewage treatment be used. A few plants for the treatment of sewage have already been installed in different parts of Canada, and it is to the operation of these plants already installed and the increasing number which will be built in the near future that these remarks are directed.

The mistake is made of deciding after the works have been installed that there is no further need for the sanitary specialist or engineer. The pursuance of this policy has been disastrous in many well-designed and well-constructed plants in the United States. Thousands of dollars have been spent for the construction of sewage work only to entrust their operation to unskilled and incompetent persons. Capable men to take charge of sewage treatment plants need a slightly different training from the constructing and designing engineer; but they should nevertheless be technically trained men. One of the leading experts in sanitary engineering recently stated that the ideal course for the operating engineer in charge of sewage treatment plants should give less attention to civil engineering features and more attention to mechanical engineering and laboratory work; also, more attention should be given to the subject of accounting and scientific management.

The work to be undertaken in the supervision of these works is not necessarily unpleasant, and it presents mechanical, chemical and biological problems which are well worthy of the time and energy of the technically trained man. The problems involved are not simple, but many of them are exceedingly complex because of the presence of biological factors. The treatment of sewage is a new and wide field for study and investigation which has scarcely been opened up.

In a recent issue of the monthly bulletin of the Ohio State Board of Health, it is stated that the larger American cities are able to employ technically trained men for this work, but many of the small cities are unable to do so; it was added that good and efficient supervision and operation of small sewage work could be secured by placing a technically qualified man over all the plants in a given district, which, in some instances, might be a single county, and in others two or more counties, the size of the district being determined by the number of plants.

This suggestion is a very good one, but would hardly do yet for the conditions existing in Canada. The plants are too few in number and too widely scattered for this method of supervision. It would appear that for some time to come the best method would be to place the supervision of the plants under the control of the Provincial Boards of Health.

◆

THE SHIPMENT OF CEMENT.

The question of how cement should be shipped is receiving considerable discussion just now. It has been argued for some time past that there would be a great advantage in shipping and handling cement on large jobs in bulk rather than in bags. One of the largest Portland cement companies in the United States has recently begun the shipment of cement in bulk. The results were so satisfactory that they are now sending out a circular urging the advantages of this method.

The wooden barrel method seems to have practically disappeared, the methods now remaining being shipment in cloth sack, paper sack and in bulk. The use of paper sacks has been strongly urged by some engineers on the ground that the return freight charges, the time and labor of collecting, counting, storing, keeping tally, packing, cartage, etc., of the cloth bags, the lost time in emptying them, the risk of loss through dampness, the risk of a dispute with the cement company supplying the cement and the risk of not getting the brand of cement specified leaves the balance in favor of the paper bag. There is a good deal of force in the above arguments, but it is unlikely that the use of the paper sack will increase much over the use of the cloth sack. The paper sack costs more to handle, and there is a greater probability of loss of cement in their use.

Shipment in bulk presents certain advantages over the cost of packing and handling cement in bags. There is a saving in cost all the way along the line. At the same time, it is extremely unlikely that shipment in bulk will ever come into general use. On large contracts, where a great deal of cement is being used, this method will give better results with a great saving in cost. The jobs, however, must be very large to warrant this method.

◆

EDITORIAL COMMENT.

An important feature that has marked a step forward for sanitary protection is the abolishment of the public drinking cup. It only remains for the Government to arrange for saloons to install the now familiar drinking mouthpiece, which will necessitate the use of a slot machine and eliminate treating the bartender.

* * * *

Attention is drawn to the article in this issue on "Canadian Draughtsmen and Engineers." The writer's suggestions deserve careful thought. The extension of the night classes in the technical schools is being done, and an impetus will be given this work, no doubt, when the long-deferred report of Royal Commission on Technical Education appears.

CANADIAN DRAUGHTSMEN AND ENGINEERS.

By **F. Tissington.**

It is with a certain amount of diffidence that I approach this subject, as, perhaps, I am not so well qualified to write about it as some others.

At the same time, I believe that, perhaps, my views may draw other people's attention to a serious handicap against Canadian engineering enterprise. What I refer to is the apparent lack of draughtsmen of almost every class, but more particularly the trained man, and further, those possessing any practical knowledge.

I have bracketed draughtsmen and engineers together in my title, because, to a large extent, the latter are recruited from the ranks of the former, and, failing an adequate supply of the first, how shall we keep pace with the demands for either class of men if our population keeps on increasing as at present, and incidentally their requirements from an engineering point of view?

To get down to the root of the matter, I would suggest that we are not training sufficient men, or training them quite the right way.

In the first place, it must be borne in mind that Canada is only in its infancy as regards engineering work, and that first and foremost it is essentially an agricultural country.

Now, from a common sense point of view it is not an easy matter to train a man for an engineer if his ancestors for generations back have been nothing but farmers, as he has a distinct bias for the land, which is a part of his heritage

Bearing these facts in mind, it is not surprising to find that we are to a large extent indebted to the States and the Old Country for a large proportion of our trained men, and who have had as ancestors workers in iron or steel instead of farmers or the like.

I would like to say right here that occasionally one sees instances of men who have come right off the land and climbed to the top of the engineering tree, but these are exceptions only, and I believe, as a general rule, environment plays a large part in what we are cut out for.

What is being done at the present time to raise up a body of men capable of carrying on the great traditions of the engineering service in Canada, or are we to be dependent upon other countries for people to fill this profession?

We have our colleges in the large towns, and presumably we are training some men in our offices and works, but, so far as I can see, no adequate scheme is in operation to satisfactorily train the men necessary to fill the positions of the future.

My experience so far has been that very few draughtsmen get a practical training; that is, they do not plough their way through the shops, and so get the fundamental knowledge of how to handle the material they are working into articles of commerce on their drawing paper, and the consequence is often seen in the inaccessibility of parts, poor details of construction, and lack of appreciation of the respective importance of things in general.

It is by no means uncommon to see the purely office draughtsman split hairs on dimensions, using 64ths, and so on, where it is totally unnecessary, and then miss the most essential points to make a workmanlike job.

There are also quite a number of men to whom technical knowledge is quite a stranger, although they claim to be draughtsmen, and it is, therefore, wholly impossible for them to do anything else but flounder.

Having thus severely criticized my own class, I would like to suggest a few ideas which would probably mitigate to some extent these faults.

First, I would suggest an extension of the evening technical schools as rapidly as could be found convenient, with grants from the Government on attendance at same.

In those districts where no such classes are available it would be a good scheme for the employers to interest themselves and get up classes in their own works suited to their own particular needs, and these could easily be run by one of the leading men if he would devote a little of his time to them. Probably the firm would be glad to make a small grant to act as an encouragement.

Then, for the practical side I would suggest that all the new men as far as possible are drafted from the works to the office, and this should act as a spur to the young men in the works to do their best and put in all the time at study they could, it being understood that those showing themselves most proficient, irrespective of age or length of service, should have first chance.

I am not at all in love with the premium apprentice system, such as is run in the Old Country. Generally speaking, the boy who stands on his own legs comes out at the finish the best man.

It will be seen that the scheme as outlined takes care of both the practical and theoretical features of the profession, and the reward of being transferred to the office, I believe, would influence quite a large percentage of young men in the works.

Some managers or owners may say that it would not appeal to them, because probably as soon as they had trained a young fellow up and improved his earning capacity he would be running away to some other shop and give them the benefit. This, however, appeals to me as a question of dollars and cents, and if the employer is not willing to pay a man according to his earning capacity, even though the firm may have been instrumental in giving it to him, then there is no doubt they should lose him.

The issue either way is entirely a business proposition, and cannot, therefore, be treated by either party as a philanthropic institution.

◆

GENERAL NOTES.

The precipitation was above the average in Eastern Ontario, over the whole of Quebec, the larger portion of New Brunswick, and in Southern British Columbia; elsewhere in the Dominion the average was not maintained. In Eastern Quebec and in New Brunswick the rainfall was heavy, varying from five to seven inches; whereas in our Western Provinces it was quite light, only a few localities reporting a total fall for the month exceeding much over half an inch.

The table shows for fifteen stations, included in the report of the Meteorological Office, Toronto, the total precipitation of these stations for October, 1912:

	Depth in inches.	Departure from the average of twenty years
Calgary, Alta.	...	..
Edmonton, Alta.	0.70	—0.06
Swift Current, Sask.	[illegible]	0.01
Winnipeg, Man.	1.10	—0.41
Port Stanley, Ont.	2.6	—0.18
Toronto, Ont.	2.35	—0.35
Parry Sound, Ont.	3.0	—0.74
Ottawa, Ont.	4.4	+2.15
Kingston, Ont.	2.9	+0.20
Montreal, Que.	3.4	+0.39
Quebec, Que.	[illegible]	0.41
Chatham, N.B.	[illegible]	[illegible]
Halifax, N.S.	3.8	—1.77
Victoria, B.C.	2.3	+0.04
Kamloops, B.C.	0.6	+0.07

REPORT OF COMMITTEE ON SEWERAGE AND SANITATION.*

In reviewing the progress of events in the field of sewerage and sanitation during the past year it is very evident that representative governing bodies in both the United States and Canada are taking a greater interest. This is particularly noticeable in regard to the districts surrounding the Great Lakes, where an organization known as "The Great Lakes International Pure Water Association" has just held its second session at Cleveland.

Pollution of Surface Water.—There appears to be a general consensus of opinion among those representing state health authorities that the time has come when some definite action must be taken by the Federal Government. This is necessary, for while one State may have most drastic laws with reference to "river pollution," the adjoining State may have none. As an illustration, the Chicago drainage canal may be cited, where, by the simple but barbaric method of turning the sewage from its own water front to a river flowing through a neighboring State, there was caused much litigation and hard feeling. This central control also applies to Canada where this question has reached the same stage and where the central authority at Ottawa is being asked to supervise surface water pollution. Representatives from the United States and Canada have already had three meetings to work out a line of action in order to obtain the necessary data on which to pass an international policy taking all the States and provinces and centralizing under one association. The following bill was introduced in the Canadian Senate last year and, after being discussed, was referred to the committee of public health, and there is little doubt but that this or a similar bill will become the law in the near future. The bill briefly provides as follows:

"Every person is guilty of an offence against this act and liable on summary conviction to the penalties hereinafter provided, who puts, or causes or permits to be put, or to fall, flow, or to be carried into any navigable water, or into any other water any part of which is navigable or flows into any navigable waters:

"(a) Any solid or liquid sewage matter; or

"(b) Any other solid matter which, not being sewage, is poisonous, noxious, putrid, decomposing, refuse or waste; or

"(c) Any liquid matter which, not being sewage, is poisonous, noxious, putrid, decomposing, refuse, or waste; unless such matter, whether solid or liquid, is disposed of in accordance with regulations or orders made or permits granted under the authority of this Act."

While such a bill is drastic, there is no doubt but that it is necessary. Throughout the United States and Canada practically all the waterways and watercourses in the populated districts are so hopelessly contaminated that they are unfit as sources of water supply unless artificially treated, and these are the principal sources of supply through this country. While it is possible to filter a polluted water it is better to filter a slightly contaminated water than an altogether contaminated water provided, of course, you cannot get an unpolluted supply. In this country at present sanitarians rely more upon filtration and treatment of water supplies than upon the treatment of sewage. The Lake Michigan Water Commission adopted a resolution in which they stated that on that lake sources of supply even twenty to thirty miles from the point of entrance of large quantities of sewage, are not safe places from whence to derive water for domestic use. The Water Commission appointed at Toronto to investigate the source of that city's supply as to Lake Ontario, found that polluted water could be obtained sometimes as far out as fourteen miles in Lake Ontario. Tests were made of water every half mile out, both at the surface and seventy-five feet below and islands of polluted water would be found at different points out for the distance mentioned. In one instance a sample was taken about one mile out and was found free of bacteria coli, with a bacterial count of 70 per c.c. Twenty feet away another sample showed bacteria coli and a bacterial count of 13,000 per c.c. This is interesting, as showing that under certain conditions of the lake and wind that the sewage polluted water does not form a combination with the colder and cleaner water. In nearly every case the samples near the surface were purer than those taken 75 feet below.

A study of the chemical analysis of the Lower Great Lakes shows that the average amount of chlorine in the water is, at Detroit 4.7, Cleveland 10, Buffalo 10 and 6.5 in the middle of Lake Erie; the west end of Lake Ontario shows that the amount of chlorine has increased two and one-half times in thirty years, while the easterly end shows that the amount of chlorine has doubled in twenty years. The increase in the chlorine indicates sewage pollution, which, if not stopped or minimized, will in time render Lake Ontario unsafe for use as a public water supply. On account of the agitation now being carried on and mentioned before, it is probable that most large cities of the Great Lakes, anyway, will be treating their sewage with the resultant decrease.

The Treatment of Sewage.—The object of all present-day treatments of sewage disposal has been to knowingly or unknowingly take advantage of the oxidation process through the intermediary of living organisms. Those that have failed are those which have not supplied these micro-organisms with a sufficient supply of oxygen to carry out their functions. In connection with sewage treatment there are two distinct factors:

(a) The removal of all causes which may effect a nuisance.

(b) The removal of all causes which may effect disease Most of the standard methods of sewage disposal using screens and sedimentation tanks perform only the functions of clarification to a greater or less extent. Filtered through slag or stone, the nuisance is altogether removed and at present only in exceptional cases is the sewage treated to effect the total removal of disease germs. On account of the great cost and the cheaper means of treating the water supply by means of the addition of very small quantities of hypochlorite of lime, as low as two parts in one million, it is very seldom that the sewage is treated beyond the filter stage. This, then, seems to be the theory of the sanitarians of the present day, namely, to only remove the chemically organic attributes which create a nuisance by decomposition, from the sewage. No longer do we find the septic tank being built, for, being wrong in principle, it is doomed as an integral essential to any method of sewage disposal. Instead, we have the sedimentation tank in some cases, and a great vogue for two-story tanks, of which the Imhoff is at present the most popular.

Water Purification.—For years we have known that sunlight is a wonderful bacteriological agent, and that the active rays were the ultra-violet rays of the sunlight. Acting on this theory, special lamps have been devised to create the greatest possible quantity of these ultra-violet rays and experiments in sterilizing water have been going on for some time. As a result, Marseilles, in France, has installed a one-hundred-and-thirty-thousand-gallon plant for sterilizing water by this means. The cost of sterilization could not be ascertained, but ninety-nine one-hundredths per cent. of the bacteria was destroyed.

---

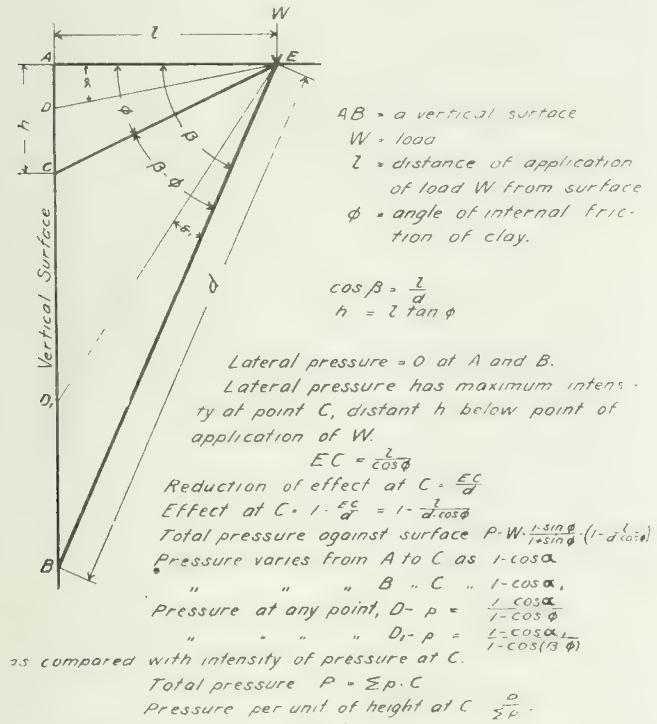
* Report presented to the annual meeting of the American Society for Municipal Improvements, held at Dallas, Texas, Nov. 12-15, 1912. Mr. A. F. Macallum, C.E., city engineer, Hamilton, Ont., chairman of committee.

Papers.—This committee has been fortunate in securing several papers on the Imhoff tanks, the purification of sewage, and the sanitary condition of Dallas. The committee wishes to extend its thanks for these papers to Mr. Y. Chalkley Hatton, of Wilmington; Prof. N. H. Ogden, of Cornell University; Mr. G. H. Daumgartner, city engineer of Dubuque, Iowa, and Mr. E. J. Dalton, of Dallas, Texas.

◆

LATERAL PRESSURE IN CLAY FROM SUPERIMPOSED LOADS.

Much has been written on the subject of earth pressure in general, and many have been the theories evolved relating to the stability of retaining walls, and the intensity and point of application of the pressure exerted by a mass of earth against the back of such a wall. In certain forms of construction the lateral pressure against a retaining wall or any vertical surface, induced by a vertical load applied at a given distance from that surface, becomes a matter of special interest. Mr. Walter L. Cowles, in a paper read before the Western Society of Engineers, gives an analysis of the lateral pressure of clay.



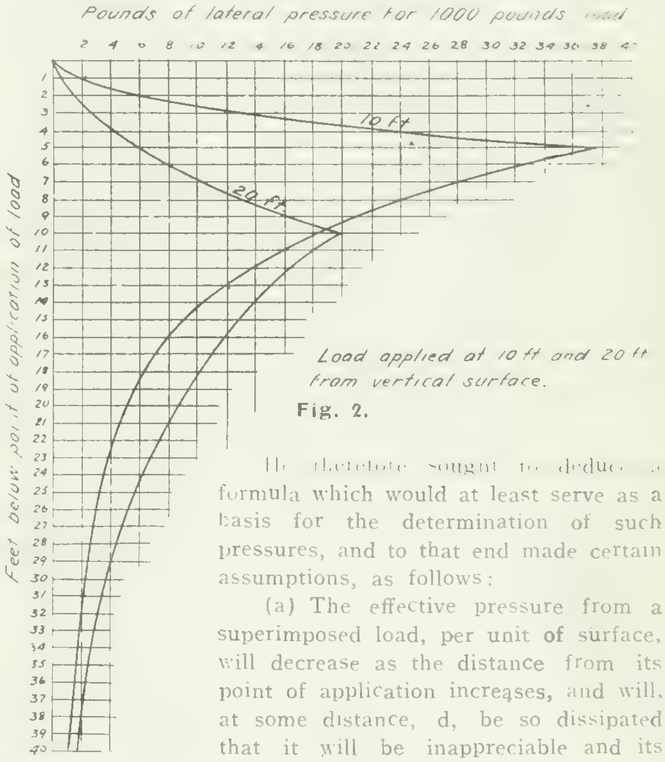
W
l
A
E
D
C
h
φ
β
β-φ
d
Vertical Surface
D₁
B
AB = a vertical surface
W = load
l = distance of application of load W from surface
φ = angle of internal friction of clay.
cos β = l/d
h = l tan φ
Lateral pressure = 0 at A and B.
Lateral pressure has maximum intensity at point C, distant h below point of application of W.
EC = l/cos φ
Reduction of effect at C = EC/d
Effect at C = 1 - EC/d = 1 - l/(d·cos φ)
Total pressure against surface P = W·(1-sin φ)/(1+sin φ)·(1 - l/(d cos φ))
Pressure varies from A to C as 1-cos α
" " " B " C " 1-cos α₁
Pressure at any point, D - p = (1 cos α)/(1-cos φ)
" " " " D₁ - p = (1-cos α₁)/(1-cos(β φ))
as compared with intensity of pressure at C.
Total pressure P = Σp·C
Pressure per unit of height at C P/Σp.

Fig. 1.

Having occasion to determine the amount of such pressure, he made a careful examination of the literature on this subject, with the result that he discovered a wide divergence of opinion as to the location of the maximum pressure as well as to its amount, varying from a maximum at the bottom of a cut to a maximum near the top, while the arguments advanced from a theoretical point of view, as well as the results of experiments and of observations of actual conditions under varying circumstances, might favor either conclusion.

Moreover, in the experiments described, the materials used were granular in character, the theories advanced were for the most part based on the action of granular substances, and the conclusions were not applicable to masses of clay such as constitute the sub-soil of Chicago.

In a few instances (notably in a paper by Wm. Cain, M. Am. Soc. C.E., published in the Transactions American Society C.E., Vol. LXXII., pp. 403-448) pressures from clay have been discussed, including the effect of cohesion. This was in line with the general direction of the investigation which Mr. Cowles was conducting, but still did not touch the particular point with which he was concerned, namely, the horizontal effect of a vertical superimposed load.



Load applied at 10 ft and 20 ft from vertical surface.

Fig. 2.

He therefore sought to deduce a formula which would at least serve as a basis for the determination of such pressures, and to that end made certain assumptions, as follows:

(a) The effective pressure from a superimposed load, per unit of surface, will decrease as the distance from its point of application increases, and will, at some distance, d, be so dissipated that it will be inappreciable and its amount may be considered equal to zero.

(b) The pressure in a horizontal direction will equal zero.

(c) The load may be considered as being supported at the apex of a cone, whose elements make an angle with the horizontal equal to the angle of internal friction of the material considered.

Clay, being a plastic instead of a granular material, has no "angle of repose," since, in excavating, it may be left with a vertical surface of considerable height; therefore this angle, commonly used in discussions of lateral pressure, is inapplicable to this material. Clay, however, has cohesion, and offers a certain resistance to shear due to its tenacity, and exerts also a resistance, due to its friction, against the movement of one portion of a mass over the underlying portion. The coefficient of this friction may be determined, and the angle of internal friction is that angle whose tangent is this coefficient.

Let us, then, consider an open cut with a vertical face, and a vertical load, W, applied at a distance, l, from the surface. Pass a plane through the point of application, and perpendicular to the face of the cut, cutting the latter in the line AB, Fig. 1. Draw the line, EC, making the angle ϕ equal to the angle of internal friction; also the line EB, making its length equal to d. By assumptions (a) and (b) the pressure will be zero at points A and B, and it is assumed as a maximum at point C.

Also, by assumption (a), at any distance, d_1, from the point of application, the reduction of effect will be equal to $\frac{d_1}{d}$, and the effective pressure will equal $1 - \frac{d_1}{d}$.

. Let the total pressure against the surface, AB, be found by Rankine's formula $= W. \dfrac{1 - \sin\phi}{1 + \sin\phi}$, reduced by the effect of the distance of C from E.

$$EC = \frac{1}{\cos\phi}.$$

$$\text{Reduction of effect} = \frac{EC}{d} = \frac{1}{d.\cos\phi}.$$

Total pressure against surface, AB, $= P = W. \dfrac{1 - \sin\phi}{1 + \sin\phi}. \left(1 - \dfrac{1}{d.\cos\phi}\right)$.

There will be pressure against the surface, AC, due to cohesion along the line (or plane, if W be considered a load per unit of length) EC, and this pressure may be considered as varying from A to C as $1 - \cos\alpha$, so that the unit pressure, p, at any point, D, as compared with the intensity of pressure at C will equal $\dfrac{1 - \cos\alpha}{1 - \cos\phi}$.

Let angle AEB $= \beta$, then will

$$\cos\beta = \frac{1}{d}.$$

Angle CEB $= \beta - \phi$.

Similarly, the pressure may be considered as varying from B to C as $1 - \cos\alpha_1$, so that the unit pressure, p, at any point, D, as compared with the intensity of pressure at C will equal $\dfrac{1 - \cos\alpha_1}{1 - \cos(\beta - \phi)}$.

The summation of the pressures against each unit of height will equal the total pressure against the surface, AB, or, if p be given in terms of the intensity at C,

$$P = C\Sigma p,$$

whence, the pressure against a unit of height at C is

$$C = \frac{P}{\Sigma p},$$

from which the distribution of pressure over the surface, AB, may be found.

This result is not offered as a final or adequate solution of the problem, but as an effort to arrive at some rational method of determining the probable lateral pressure exerted against a vertical surface by a vertical load at a greater or less distance, and the distribution of this load over that surface.

The values of both d and Φ will vary with the consistency of the soil, and d, especially, will be determined largely according to the judgment of the individual.

As an illustration of the results of this method, and without implying that the values are worthy of adoption, Mr. Cowles assumed in the figure an angle of 26 deg. 30 ft., equal to a slope of 2 to 1, for the angle of internal friction, and if a distance of 100 ft. be assumed for d, the curves of pressure for load applied at distances of 10 and 20 ft. from the vertical surface will be as shown in Fig. 2. The area included between the curves and the vertical line representing the surface will equal the total pressure against the surface.

The Imperial Limited Canadian Pacific Express, westbound, was derailed Sunday night by a broken rail, four cars leaving the track near Wayland Station, 280 miles west of North Bay. Traffic was delayed about six hours by the accident

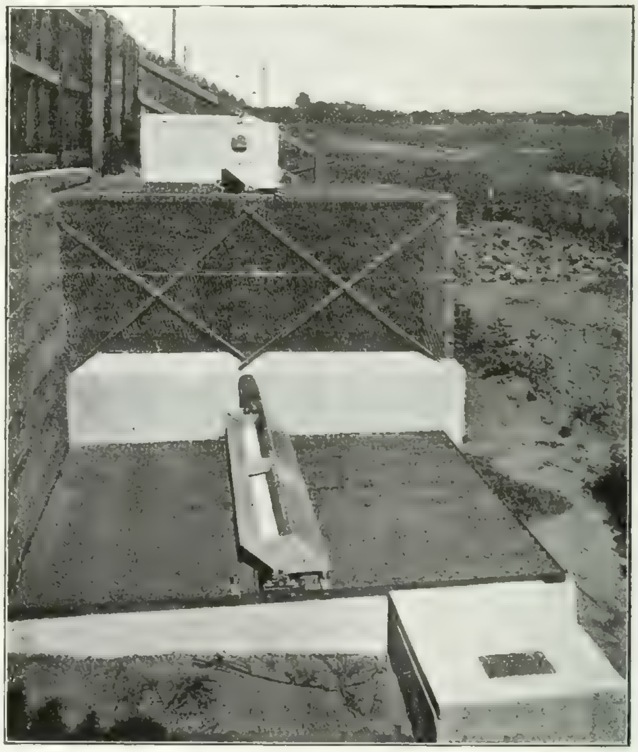
---

A SMALL SEWAGE PLANT.

By H. C. Clark.

For some time past difficulties have arisen in disposing of the sewage from Twyford Station, England, on the Great Western Railway Company lines, there being no local sewerage system. Various expedients temporarily tided over the requirements, but the necessity for more thorough steps became evident and plant was provided which represents the latest methods of scientific treatment about a year and a half ago. This plant follows the process by which Nature clears away effete organic substances, i.e., by fermentation and oxidation, in the order specified.

The second process occurs in filter beds about 4 ft. 6 in. deep, served by iron distributing trays, a tipper automatically deflecting to each filter bed alternately. The medium in these filters, between which an air space intervenes, is hard clinker, carefully washed, screened and graded; and the object of this provision is to develop the gelatinous growth in the interstices of the clinker and also to promote free oxidation, the anaerobic action being supplanted by the development of aerobic bacteria, for which a medium containing air is necessary, while the converted product, termed "humus," is retained in a small pit. The final purification is effected by a clinker drain. Special provision in the form of baffles and drain-off valves arrest and extract a quantity of paraffin oil used for cleaning the sanitary fittings.



View of Sewage Plant at Twyford Station in Operation.

The plant was designed to the approval of the divisional engineer, Mr. J. N. Taylor, and provided by Messrs. Tuke & Bell, Limited, sewage specialists, 69 Leadenhall Street, London.

The plant has now been in operation for a year and a half successfully, without a complaint from the Rivers Board, although the sewage from the station is an exceptionally strong one, and difficult to treat.

THE BUILDING AND ORNAMENTAL STONES OF THE MARITIME PROVINCES.*

By Professor W. A. Parks.

The economic production of stone for structural purposes in the Maritime Provinces is practically confined to granite and sandstone. A brief account of the condition of the industry is given below for each province separately.

NEW BRUNSWICK.

Granite.—The red, pink, and grey granites of St. George and the black granites of Bocabec, in Charlotte county, are being quarried by several firms; the product is nearly all manufactured into monuments in the extensive mills at St. George. In this country also, there is a small and intermittent production of grey granite from the vicinity of St. Stephen.

Near Hampstead, on the St. John River, the so-called Spoon Island stone is worked in two extensive quarries by D. Mooney & Company, of St. John. Both pinkish and grey, rather coarse-grained stone is obtained which is employed for monuments, for building, and for the making of paving blocks.

The rough grey granite boulders which are so plentifully scattered over the area north of McAdam Junction, in York county, are cut into building blocks by different operators and employed for structural purposes in Woodstock and other towns.

Near Bathurst in Gloucester county, a coarse-grained granite is from time to time quarried for local use.

Sandstone.—Roughly speaking, the sandstones of New Brunswick may be classified into red, grey, olive-green, and brown types. An excellent red freestone is quarried near Sackville, in Westmorland county, by the Sackville Freestone Company. The formation at this point is very favorable for the profitable extraction of stone. Large quantities are quarried and dressed by a modern plant, the product, in many cases, being shipped to a distance.

True grey sandstones occur along the Gloucester coast of Chaleur Bay; they are quarried by two companies for the making of grindstones. The cost of quarrying is, however, too great to allow this material being put on the market as a building stone.

Olive-green sandstone is quarried in Northumberland, Kent, and Westmorland counties.

The quarry region in Northumberland is situated on the Miramichi River, near Newcastle. Two firms are now actively engaged—the Miramichi Quarry Company, Quarryville, and Adam Hill, Cassilis. C. E. Fish, of Newcastle, proposes to reopen the old French Fort quarries at an early date.

In Kent county olive-green sandstone is quarried near Notre Dame, on the Moncton and Buctouche railway, by Hall and Irving, of Moncton.

Westmorland county was for many years the chief seat of the freestone industry in New Brunswick. At the present time a great many of the old quarries near Shepody Bay and Cumberland Basin are idle. H. Read and Company are operating a quarry at Northport, and the Dorchester Stone Works have a small quarry on the point between the Petitcodiac and Memramcook Rivers. Near Shediac, Dr. E. G. Smith is producing a stone which may be included in this class.

Brown sandstone is quarried by the Read Company, at Wood Point, in Westmorland, for grindstones, and the Cape Bald Freestone Company, of Port Elgin, is getting out building blocks at Cape Bald, on the eastern coast of Westmorland.

Crystalline limestone is largely quarried for the manufacture of lime at St. John, with the incidental production of a small amount of rough building stone.

The pure white gypsum at Hillsborough, in Albert county, has, in the past, been employed as a decorative stone, but there is no production for that purpose at present. The porphyritic felsites of Passamaquoddy Bay, the Tobique Valley, and elsewhere may have a future value as decorative stone but they are not at present utilized.

NOVA SCOTIA.

Granite.—A greyish, coarse-grained, and porphyritic granite is quarried by several firms along the Northwest Arm, near Halifax. At Terrence Bay, a coarser and lighter colored type was quarried for the construction of the Bank of Commerce in Halifax.

On the west side of Shelbourne harbor, in Shelbourne county, a very fine grey granite was formerly obtained. The character of the stone and the excellent shipping facilities should encourage the further exploration of this deposit.

At Nictaux, in Kings county, are extensive exposures of an excellent fine-grained grey granite resembling the famous stone from Barre, Vermont. The Middleton Granite and Marble Company, Thelbert Rice, S. Williamston, and John Kline, of Halifax, are quarrying this stone for structural and monumental purposes.

Sandstone.—The sandstones of this province are, for the most part, of an olive-green or reddish color, and are obtained more particularly in Cumberland and Pictou counties.

The most important quarry of red stone is that of the Amherst Red Stone Quarry Company, near Amherst. Two small operators are producing a reddish stone near River John, in Pictou county. At Toney River and other places along this coast, as well as at Whycocomagh and Judique, Inverness county, Cape Breton, there was a former production of red sandstones.

Olive-colored sandstones were at one time extensively quarried along the coasts of Chignecto Bay and Northumberland Strait, in Cumberland, Pictou, and Antigonish. In Cape Breton they were obtained, more particularly, on Boularderie Island and at points near Sydney. At the present time there are only two quarries worthy of mention here, although small amounts of stone are raised by other operators. The quarries of the Wallace Stone Company, at Wallace, in Cumberland county, have furnished stone for many of the chief buildings in Eastern Canada, and are still in active operation. The Pictou Quarry Company, of Pictou, produces a fine grade of stone which rivals the Wallace product in popularity.

Metamorphosed Slate.—A hard stone of this character is quarried on the Northwest Arm below Halifax. The product is largely employed for purposes of rough construction and, in some few cases, has been used in buildings of a higher type.

Crystalline Limestone.—The demand for flux in the steel plants has led to the opening of very large quarries at Marble Mountain and George River, in Cape Breton. Good exposures have in consequence been made which reveal the shattered nature of the formation. Although fair-sized pieces of considerable beauty could be obtained from time to time, there does not seem to be much promise of success in the operation of these quarries for marble. Variegated crystalline limestones of marble quality are known to occur at other points in Cape Breton: among these may be particularly mentioned Whycocomagh and Eskasoni. No positive evidence was obtained that these deposits are capable of economic working, as they are much covered by soil and present only isolated exposures.

---

* Abstracted from summary report of the Mines Branch, Department of Mines, for 1911.

Felsite-breccia.—Along the coast of Richmond and Cape Breton counties, and more particularly on the north shore of Scatari Island, handsome, varicolored felsite-breccias occur. Although this material could not be secured in very large blocks, pieces of sufficient size for many decorative purposes could be readily obtained. Somewhat less brilliant but still handsome felsites may be obtained at many points in Pictou, Antigonish, and Guysborough counties.

PRINCE EDWARD ISLAND.

The only stone suitable for building produced in this province is a red and not very durable sandstone of the Permo-Carboniferous age. Small and unimportant quarries have been opened at many places, but the only production at present is from Swan's quarry, near Charlottetown.

In the Maritime Provinces, as in other parts of the country, the stone industry has suffered severely from the general introduction of cement for purposes of construction. Those quarries which formerly produced heavy stone of a coarse type for bridge building and other works of a like nature are practically all closed. The long haul by rail to the chief centres of consumption is a deterrent factor in the profitable working of the finer grades of sandstone. The failure of the numerous quarries about the head of the Bay of Fundy has been ascribed to the almost prohibitive duty imposed by the United States government. This same factor has had much to do with the closing of the granite quarries at Shelbourne. It is encouraging to observe that Wallace, Pictou, Sackville, Amherst, and Miramichi stone can be profitably quarried and shipped to points as far distant as Toronto. It should be remembered also that many of the old quarries at Mary Point, Demoiselle Creek, Boudreau, etc., were operated almost entirely without machinery. Strong companies with modern equipment might well be able to revive the industry in this district.

The granite quarries of Charlotte county are handicapped by the long haul by team into St. George, by the small scale on which operations are conducted, and by the fact that no outlet is found for the large amount of debris. The stone has been quarried for monumental or large structural work only: in consequence, immense piles of material have accumulated from which paving blocks and even building stone of fair size could easily be cut. It is stated that an effort is being made to form a company embracing the various interests. It is to be hoped that such an attempt may meet with success, for such a company could concentrate the quarrying, provide better means of transportation, and devise ways for the utilization of the smaller stone.

◆

WATER STORAGE IN BRITISH COLUMBIA

A good example of what can be done in developing and, at the same time, conserving water-power resources is given by the Jordan River plant of the British Columbia Electric Railway Company, on Vancouver Island. Although the average precipitation over its watershed reaches the excessive figure of 80 inches, the Jordan River, like the majority of our streams, has a wide variation between summer and winter flow. The company has had the flow of this river systematically gauged since 1907 and the results obtained justified the building of large storage reservoirs for the purpose of impounding waters which would otherwise go to waste. The total capacity of these reservoirs, of which there are five, is 1,500,000,000 cubic feet, and they provide ample storage, within reasonable cost, for an ultimate maximum plant output of 24,000 h.p. to 36,000 h.p.

REPAIRING OF UNARMORED CABLES IN WET SHAFTS.

In a paper read before the East of Scotland Branch of the Association of Mining Electrical Engineers, Mr. J. Gillespie gave an interesting account of his experience with the above.

While there may be some room for divergence of opinion as to the respective merits of armored versus unarmored cables for shaft work, there can be very little room for any difference of opinion with regard to the great difficulty experienced in the execution of repairs on cables which come under the latter category, particularly when they have to withstand the stress of high-tension currents in wet or damp situations.

On a recent occasion the writer had some connection with a colliery at which the shaft cables were a source of continual trouble, they having on successive occasions broken down to earth on one or more phases. The cables in question consisted of three conductors of 37.14 copper insulated with vulcanized bitumen, taped and double-braided, installed in a pitch-pine casing 9 in. broad, which was screwed to the end tubbing of the pit, each conductor being in a groove by itself and the whole capped with 1-in. pitch-pine boards.

Prior to the writer's connection with the colliery several attempts had been made to eliminate the trouble, the method adopted being to build a substantial wooden box round the part affected, which box was then filled in solid with bitumen or some insulating compound. This improved matters for a time, but had no lasting effect, as another defect made itself apparent soon after each repair, at a point immediately above the range of the compound.

When the trouble first attracted the attention of the writer, he made a complete investigation, and became convinced that the root of the matter lay in a quantity of water finding its way into the casing at the junction where one length butted against the other. Water was found in appreciable quantities in each groove, the braiding of all three conductors being saturated while a continual stream flowed in the part of the groove between the cable and the capping. On consideration it was decided that it was impracticable to exclude the moisture from the casing, and that it was impossible to effectually insulate the cable in presence of the water. The alternative which presented itself to the writer's mind was that by some means the cables and casing should be removed from proximity to the water. The volume of water passing the affected part was found to be about two gallons per minute.

Fig. 1 shows the discarded method of repairing the cables. The wood box is shown fastened to the tubbing and surrounding the casing on three sides. One great defect of this is that it leaves the back of the repaired part exposed to any water which may find its way through the interstices of the barring. In addition to the presence of water in the casing, there had also to be considered the presence of a large amount of water in the open shaft, which at times was increased by the overflow from a small lodgment situated above and almost directly in the line of the cable run.

The cables having been placed behind the buntons it was necessary to arrange suitable water scaffolds between the buntons and the tubbing under which to carry on the work. These scaffolds were fixed in such a way as to divert the falling water, and were given such a run as would carry the collected water away from the casing in the direction of the tubbing, thus obviating the chance of the jointer's clothing becoming wetted by the drip water; in which case there would be present the risk of his carrying moisture to the joint.

The first step was to cut out the part of the cables which had been under the influence of the recurring earths. This was a length of 6 ft., and the casing was also taken out in such a way as to lay bare about 2 ft. of sound cable at both top and bottom. At the part from which the casing was removed a stout pitch-pine batten was fixed 3 in. from the barring by means of iron brackets, the space between the tubbing and the batten being left in order that any water which percolated through and was flowing inside the casing, might drip down clear of the joints. To this batten was screwed a length of casing in which were placed three pieces of new cable which had already been tested and proved to be impervious to water. The three protruding tails of the old cable at the part nearest the surface were then bent swan-neck fashion, the ends of each being turned down to meet the corresponding end of the new cable, and each conductor was jointed by means of a copper sleeve fastened to the cores by pinching screws and sweated solid. Pains were taken to arrange the bends in the cables in such a way that the water which found its path in the grooves of the casing was bound to drip from the rearmost convolution of the bend and fall clear of the joint. The major portion of the water being thus disposed of, the cables were heated gently over a protracted period in order to drive out the moisture saturating the braiding. This was carried out before making the joints, and continued until the cables were perfectly dry.

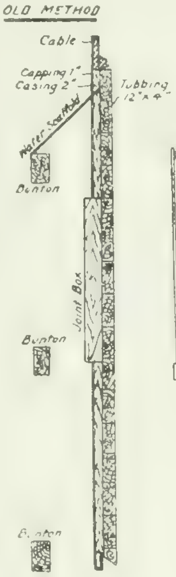


Fig. 1.

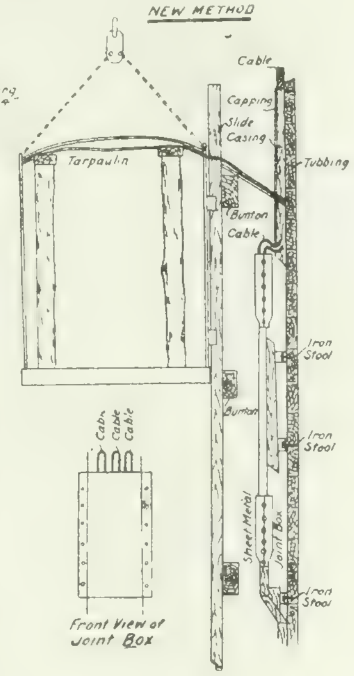

Fig. 2.

The drying process had to be repeated immediately before the box was filled in solid with compound, as it was noticed that some moisture showed a tendency to creep along the braiding even where it had to travel over the almost vertical portion of the bend in an upward direction. This the writer attributes to capillary attraction.

A joint box made up of 3/32 in. sheet iron (bent into the requisite shape at the Colliery) was then placed over the joints and was firmly glanded to the casing. Rubber insertion was used between the two portions of the box and between the box and the casing as jointing material, on account of its non-hygroscopic properties. Fig. 2 includes an enlarged sketch view showing the front elevation of the joint box with the cables entering same from above. Diatrine compound was used to fill up the box, and during the progress of the filling and for some time after the box had been filled a blow-lamp flame was kept playing on the front and sides of it so as to ensure that all traces of moisture were eliminated. At the lower end of the repair a similar joint box was used, but at this point there was no need to put close bends on the cables, as on account of the water-shedding arrangements prepared for the upper joint, that part of the casing immediately above the lower was found to be comparatively free from moisture. The work having been carried out at a holiday time, it was possible to make use of the cage for lengthy periods without unduly interfering with the output. The length of time occupied with the work was bounded by the period during which it was possible to keep the dock pumps idle without danger.

In order to arrange an almost completely water-tight structure from which to carry on operations, the ironwork forming one side of the cage was removed, and a tarpaulin fixed up in pitman fashion, by means of trees. This arrangement was carried out immediately under the cover of the cage, and one part of the tarpaulin was draped to form a flap, which, when the cage was in position for carrying on the work, was laid on the upper side of the water-scaffold to form with it a fairly water-tight roof some 8 ft. in length by 7 ft. in width. This permitted of tools and other gear being laid down in a dry position, besides providing more comfort than is usual in shaft work. Fig. 2 illustrates how the work was carried to completion. It shows the upper and lower joint boxes with the cage in position for making the upper joints. The work has been completed for a considerable period, and as yet shows no sign of recrudescence of the trouble. The cure is apparently of a permanent nature.

The writer does not intend that these few remarks should be construed into an argument in favor (or the reverse) of any particular type of cable, but hopes that they may be of service to any member who may encounter similar difficulties. He further hopes that during discussion, modification or improvement may be suggested of which he may take advantage should the repair as outlined turn out to be other than permanent.

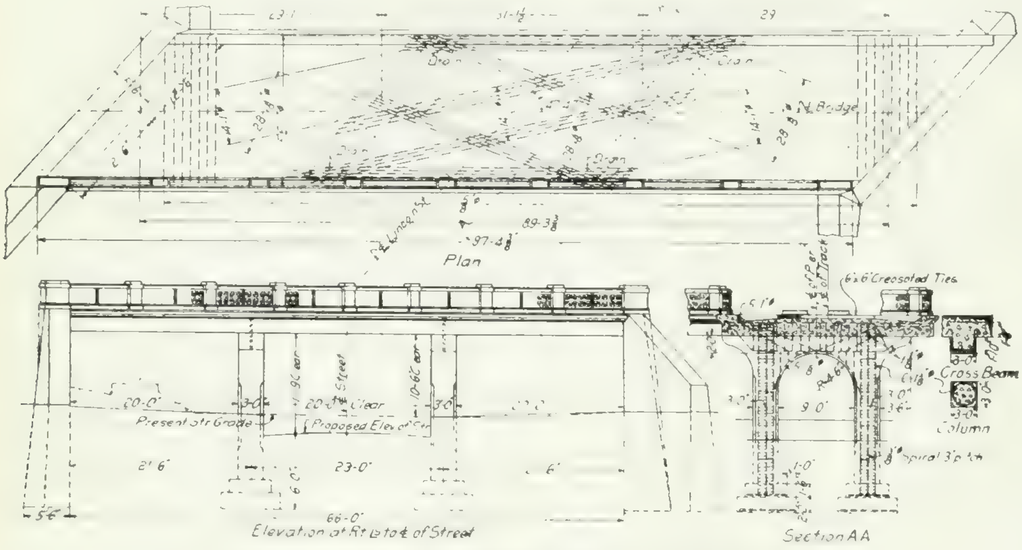
◆

CALGARY WANTS NATURAL GAS AS PUBLIC UTILITY.

The possibility of acquiring natural gas as a public utility is exercising the minds of many prominent citizens of Calgary. Since the introduction of the gas on a large scale by the Canadian Western Company, the convenience of its use in residences has been brought closer to more people. There is no complaint that at 35 cents per thousand feet it is too expensive when properly used, but having in mind the many wells scattered throughout Alberta where only a small portion is being used, or none at all, the question is freely asked why the city should not have its own supply? True, there is a well within the city limits piped into many houses and used extensively for lighting the streets east of the Elbow River, but its depth, 3,300 feet, and the difficulties met with when it was drilled, rather discouraged any further attempts just then. There is a pressure of 230 lbs. to the square inch at this well. At Bow Island the pressure is 800 lbs. But large manufacturers, though they may, with this gas at present prices, produce power at a cost of under $10 per horse-power per annum, would be more readily induced to locate in this city if that rate was reduced, a concession that the present company is not prepared to make. Hence it is advocated that the city ask the ratepayers to sanction an expenditure of $100,000 on the chance that a sufficient quantity can be tapped at a reasonable depth.

REINFORCED CONCRETE SLAB BRIDGE.

The Minneapolis, St. Paul & Sault Ste. Marie has adopted concrete slab bridges, reinforced by the "mushroom" system, for a number of highway crossing locations. This system of reinforcement, patented by C. A. P. Turner, consulting engineer, Minneapolis, has been in use for some time in building construction, but has not been widely adopted for railway bridge construction. Two bridges built in the town of Amherst, Wis., are typical of these structures. The details of the Lincoln Street bridge are described in a recent issue of the Railway Age Gazette and are shown in the accompanying illustration.



Plan and Elevation of Subway Built at Amherst, Wis.

The street is crossed on a skew of 47 deg. and 40 min., the abutments and piers being parallel at an angle with the centre line of the street. The piers consist of two reinforced concrete columns 3 ft. square spaced 12 ft. centre to centre, connected at the top by a concrete beam. The footings are spread to 7 ft. square and are reinforced in four directions, as shown in the drawing. The columns are reinforced by six 1⅛-in. round rods set vertically and banded spirally by ⅜-in. round rods on 3-in. pitch. The columns are 14 ft. 3 in. high from top of footings to bottom of slab, and the corners are chamfered to a depth of 3 in. The transverse beams, which have a minimum depth of 2 ft. below the slab, are arched between columns and are carried out beyond the columns on the curved lines shown in the accompanying cross section. The beams are reinforced in the upper plane by five 1-in. round rods, and in the lower plane by eight 1⅛-in. round rods bent up for shear reinforcement, and five 1⅛-in. rods bent down for surface reinforcement over the arch. In addition to this, there are ⅜-in. stirrups spaced 12 in. centre to centre between column reinforcements.

The floor slab is reinforced in four directions, in accordance with the usual "mushroom" design, the rods being crossed over each column in the piers. The reinforcement parallel to the centre line of track consists of 1-in. round rods spaced 4 in. centre to centre, and that perpendicular to the centre line of tracks of ⅝-in. rods spaced 12 in. centre to centre. The diagonal reinforcement connecting alternate pier columns consists of 1⅛-in. round rods for the shorter lengths and 1-in. rods spaced 6 in. centre to centre for the longer lengths. The central span is 31 ft. 1½ in., and the two sidewalk spans are 29 ft. 1 in. Drainage is carried in troughs built in the upper surface of the slab on either side of the ties to outlets over each pier. The clearance over the street level is 11 ft. 9 in., and between railings 16 ft.

A similar bridge over Wilson Street was built first. In this case turnouts were installed and a temporary pile trestle was driven alongside the old structure, over which trains were operated during the construction of the new bridge. In building the Lincoln Street bridge, however, traffic was maintained over the structure during the construction work. To accomplish this, the jack stringers, guard rails and long ties were removed and the deck of the original pile bridge was jacked up about 2½ ft., run-offs being provided at both ends by cinder fills. The track was blocked up in this position on cast iron spools. These spools were 2 ft. 3 in. long and 10 in. in maximum diameter, placed so as to not interfere seriously with the slab reinforcement. They were concreted into the floor slab and allowed to remain in the position shown. The forms for the concrete slabs were built on the old trestle, effecting a saving in the cost of false work. This hump in the track made it necessary to operate carefully over the bridge during construction, but traffic was never interrupted. These bridges were built under the direction of Thomas Green, chief engineer, and C. N. Kolk, principal assistant engineer.

PATENT AND TRADE MARKS.

We have been forwarded the following news item which appeared in the Manchester Guardian, by Mr. Egerton R. Case, foreign member of the Chartered Institute of Patent Agents, London, registered patent attorney, Temple Building, Toronto:

"I learn that one of the last questions discussed between the Canadian Ministers and the Government relates to a scheme that is being prepared by the Board of Trade for the assimilation of the laws of patents and trade marks in the United Kingdom with those of Canada and of the other dominions. This question was first raised at the conference of colonial premiers in 1902, and again at the imperial conferences of 1907 and 1911. The majority of the patents issued in the self-governing dominions are granted in Canada, and the number granted in any one year in the whole of the dominions amounts to considerably more than half of those granted in the United Kingdom. It has been generally agreed that uniform legislation on these subjects should be established. In the United Kingdom a patent may be granted to one or more applicants. In Canada a patent may be obtained by the inventor or his assignee. In Australia the applicant for a patent may be the actual inventor or his nominee. In New Zealand one of the applicants for a patent must be the first inventor. In Newfoundland before any person can obtain a patent he must make an oath in writing that he is the inventor or discoverer. In the Transvaal and the Orange Free State one or more of the applicants must be the first inventor or his legal representative. The object aimed at by the Board of Trade is that a patent granted, say, in London should have validity right through the Empire.

THE DEVELOPMENT AND STATUS OF THE WOOD PRESERVING INDUSTRY IN AMERICA.*

By E. A. Sterling.†

The literature on the subject of wood preservation in America is voluminous, but so fragmentary that a summarized review of the developments and present status of the industry is, perhaps, justified because of the importance of the question to scientific and commercial interests.

The first recorded use of treated ties is that of kyanized chestnut, laid in the tracks of the Northern Central in Maryland in 1838, which were still sound when examined eleven years later. Kyanized oak trees, laid in the tracks of the Chesapeake and Ohio in 1840, were sound when examined fourteen years later.

The first treating plant, worthy of the name, was probably that built at Lowell, Mass., in 1848, by the proprietors of the locks and canals at that point. The plant consisted of two wooden tanks, each 50 feet long, eight feet wide and four feet deep, in which the lumber was immersed in accordance with the kyanizing process, using bichloride of mercury. Prior to 1895, several temporary plants were constructed by railway companies, among those being one established by the Central Vermont in 1856; another by the Erie in 1861, at Owego, N.Y.; another by the Union Pacific in 1867, at Omaha, and one by the Philadelphia, Wilmington and Baltimore in 1863, all of these being for the use of zinc chloride by the burnettizing process. The first permanent railway plants were built in 1875 and 1876, one being constructed by the Louisville and Nashville at West Pascagoula, Miss., which is still in operation, and the other by the Houston and Texas Central. Both were creosoting plants.

In spite of the many attempts at wood preservations during the past forty years, the rapid and permanent developments have mostly occurred during the past ten years. In 1900, there were eleven plants in operation, while at the beginning of 1912 there were about one hundred, with several more under construction or authorized. Prior to the year 1900 the most definite developments were in the West, where scarcity of timber forced the railways to adopt measures by which longer life could be given their cross ties. We thus find that the Southern Pacific has a burnettizing plant which has been in operation since 1867, while a plant using the same process was put into service by the Santa Fe in 1885. The latter road has since adopted the Reuping creosoting process. Several commercial plants were also built in the western part of the United States prior to 1900, but the general adoption of preservative treatment throughout the United States, particularly by the eastern roads, has all been during the last ten years.

In Canada the developments have been even slower than in the United States, and it is only within the past two or three years that treating plants of any size have been put into operation. At present the Canadian Pacific and the Canadian Northern either use treated ties from plants already in operation, or have arranged for the construction of plants. In Mexico and South America little or nothing has been done, although some of the Mexican roads have experimented extensively with crude oil and several plants have been built. In South American countries there are no plants, as far as the writer's knowledge goes, but large quantities of creosoted material have been shipped from plants in the United States for use, particularly in marine work.

At the beginning of the year 1912, 101 plants were listed by the American Wood Preservers' Association. Of this number, twenty-five are owned and operated by railway companies, and twelve in addition are maintained solely for railway work. The remainder do a general commercial business. The industry in the United States, up to the present time, has been built up largely on railway cross ties, yet out of the 148,000,000 ties used in 1910, according to census figures, only 26,000,000, or about 18 per cent., received preservative treatment. This, however, is an increase of 275 per cent. over the number treated in 1905. During the year 1910, there were also treated approximately 133,000,000 board feet of lumber, which represents only 0.33 per cent. of the total consumption. The total output of all treated material in 1910 amounted to slightly over 100,000,0000 cu. ft., which was 500 per cent. more than was treated in 1904. To treat this amount of material in 1910 there were consumed approximately 17,000,000 pounds of zinc chloride and 63,000,000 gallons of creosote, 71 per cent. of which was imported.

In 1911, according to statistics compiled by the American Wood Preservers' Association, a total of 110,372,660 cu. ft. of material was treated in the United States, this being an increase of 10 per cent. over the previous year and a 62 per cent. increase over 1907. Of this amount, 84,672,370 cu. ft. consisted of cross ties, 3,910,740 cu. ft. of piling, 1,085,971 ft. of poles, 10,140,474 cu. ft. of paving blocks, 6,831,416 cu. ft. of construction timber and 2,568,857 cu. ft. of lumber and miscellaneous material. By kinds of treatment 73,558,621 cu. ft. were treated with creosote, 29,501,665 cu. ft. with zinc chloride and 7,312,374 ft. with zinc chloride and creosote.

The kind and character of the timber treated varies greatly in different sections of the country. In the northeastern States the bulk of the material is hardwood, including red oak, beech, birch, maple and pine, which is shipped in by water from south Atlantic States. In the Lake States and the upper Mississippi valley the cross ties treated are almost exclusively hardwood of the species above named. In the south Atlantic and Gulf States, and to some extent in the Southwest, pine is used almost exclusively; while in the lower Mississippi valley and adjacent territory both black and red gum are being treated with apparent success. In the West and Northwest the wood most largely used for treatment is red fir. Considerable difference of opinion exists as to whether the so-called sap pine is suitable for cross ties. It is used extensively by some of the railways in the South and Southwest, where traffic is comparatively light, but the experience of the railways in the northeastern States, where traffic is heavier, indicates that the soft sap pine does not hold the spikes well and is not sufficiently resistane to rail-cutting.

At the present time only two standard preservatives are in general use in the United States, namely, creosote and zinc chloride. Of these, creosote seems to be gaining ground steadily, while zinc chloride is used mainly in the semi-arid regions of the Middle West or in combination with creosote. It should be mentioned that the Santa Fe is making very extensive experiments with a crude oil which carries a high percentage of asphaltum. While possessing no toxic properties this oil seems to effectively close the pores of the wood and act as an inert filler against the entrance of air, moisture and fungus spores. In later experiments a mixture of natural asphaltic oil and creosote has been used. In addition to the accepted preservatives named, many manufactured preservative compounds are on the market. Most of these are intended only for superficial application with a brush or in open tanks. Although the number of accepted preservatives has been reduced to two or three, several different and distinct processes for introducing the solutions into the wood are in general use. Each of these has its ardent advocates, and each has points of merit which can hardly be disputed. The following table summarizes the processes now used in America. The high-pressure processes are most generally used, and, while the so-called open tank or atmospheric pressure and the low-pressure treatments have been used quite extensively by small concerns which could not afford expensive plants, it may be expected that the pressure treatment will prevail almost universally within a short time:—

---

* Presented at the Eighth International Congress of Applied Chemistry, September, 1912.

† Forest and Timber Engineer; president of the American Wood Preservers' Association.

High artifical pressure processes	Full cell	Bethell—creosote. Burnett—zinc chloride. Wellhouse—zinc chloride, glue and tannin. Card—zinc chloride and creosote. *Crude oil—natural asphaltic oil. *B. & M.—zinc chloride and aluminum salts.
	Empty cell...	Reuping—creosote. Lowry—creosote.
Atmospheric pressure processes	Full cell	Soaking in cold preservatives. Soaking in hot preservatives. Alternate hot and cold treatments.
	Empty cell ..	Hot, cold and hot treatments. Hot and graded cooling treatment
Low artifical pressure processes	Full cell ..... Empty cell...	

* May be considered as still in the experimental stage.

In addition to the above, kyanizing and vulcanizing plants are still operating in New England, the latter being a rapid drying or baking process without the use of a solution.

The question of specifications and standards and many important technical points requiring consideration do not come within the province of this paper. Zinc chloride, being a mineral salt, can be manufactured to meet definite specifications. Since crude oil is a natural product, it is necessary to procure the supply from oil wells which produce the quality desired, namely, that with a very high percentage of asphaltum. The oil which has been found most suitable for preservative treatment is that known as Bakersfield oil from southern California, also from certain districts in Mexico.

In the matter of creosote specifications much more difficulty is encountered. Coal tar and creosote being a by-product of a by-product, and not manufactured exclusively for preservative purposes, varies greatly in its chemical composition, and except by re-distillation cannot be made up to meet too strict specifications. The consumers have rather definite ideas as to the quality of creosote desired, but unfortunately it has been necessary to base the specifications on the kind of oil available, both abroad and in this country, rather than to make arbitrary standards and expect the manufacturer to meet them.

Several additional problems relating to the use of creosote as a preservative are pressing for solution. These include the advisability of using various mixtures of creosote and other products, such as filtered tar, water gas oil, or the combining of creosote of different grades, the use of water gas creosote either alone or in combination with pure coal tar creosote; the value and possible use of oil from coke over tar; and the combined use of creosote and crude oil.

The mechanical equipment of the modern American plant leaves little to be desired. High pressure cylinders six or seven ft. in diameter and up to 150 ft. long are practically the standard. Labor-saving devices are in much more general use than in Europe, and hand work is reduced to a minimum. One of the important recent improvements [illegible] the measuring and weighing tanks are mounted on scales, so that the amount of creosote or other solution absorbed is measured closely by weight rather than by volumetric scale readings.

Automatic devices for unloading full tram carloads and machines which adze, bore, saw to even length and stamp with the date ties before treatment, are included among the mechanical developments.

The present tendencies are towards lighter impregnation with creosote, except in construction timber, or the use of mixture, which reduces the initial cost. No less than sixteen of the plants listed by the American Wood Preservers' Association use a light impregnation creosote process, and probably as many more use it on at least one part of their material, while several more plants use zinc chloride and creosote in mixture. This means that a large percentage of the treated cross ties used by the railways have less than six pounds of oil per cubic foot. Actually, they have more than six pounds in the treatable or sap portion of the tires, because the absorption is figured on the gross cubic contents. It may be argued that these light treatments are poor economy in the long run, and it is indisputable that they have not had the test of time. It must be remembered, however, that wear under the rail is responsible for a large percentage of tie failures after five years, and that full impregnation would certainly not be justified without large and expensive tie plates and screw spikes. Recent developments in the adzing and boring of ties before treatment promises a solution of the question of mechanical wear in relation to impregnation and decay.

Apart from the many details which are in a fair way of being worked out, there are two very broad problems which confront the wood preservers of America, and to which they should give their attention if the industry is to remain permanent and profitable. One of these is the source of supply for creosote oil, the present indications being that a shortage is imminent and that high prices will prevail. While the consumers can, perhaps, do little of themselves to stimulate production, they can at least co-operate with the manufacturers and encourage the construction of by-product ovens in America, and maintain trade relations, which will guarantee to the European distillers a definite market for their available creosote. Enough creosote is burned in the beehive coke ovens of the United States every year to supply all reasonable demands for years to come.

The other problem is that of timber supply, and it is one to which the wood preservers have paid too little attention. This applies to the owners of commercial plants, and particularly to the large railway companies which either operate their own treating plants or have their work done by contract. At the present rate of increase, the cost of treatable cross ties and other material will, in a very short time, be equal to that of white oak and other more durable woods. There are still enormous supplies of cheap woods available, and it is for this very reason that steps should be taken to perpetuate the supply. In some regions, however, the supply of treatable timber is already becoming depleted, and many plants will have to seek new locations or have their material shipped long distances within the next ten or twenty years.

Most of the hardwood timber, suitable for treatment, is of such slow growth that under present conditions it would not be profitable to reproduce it under any system of forest arrangement. In the South, on the other hand, are several fast-growing trees which would respond very readily to a system of conservative management. In the loblolly pine belts, for example, the output of timber from a definite area could easily be made permanent. It is estimated that about 100,000 acres of well-stocked loblolly pine land would produce 1,000,000 ties per annum for all time. It would have been very easy at the time some of the first railway plants were built to have acquired timber lands at comparatively low cost, and by proper management made them a permanent source of cross tie supply. This has not been done.

GAS AS A MEANS OF HOUSE HEATING.

By Lyman B. Jackes.

The adaption of gas, both natural and artificial, to house and building heating is a problem that has been worked upon by several inventors. The factors which were in favor of the commercialization of the scheme are many.

First there is the point that would appeal to many householders, viz., the elimination of ashes. A second might be considered to be the handling of coal, and this at once suggests the storage of that fuel and the use that could be drawn from the space, providing the coal could be dispensed with. The varying qualities of the coal, to say nothing of the tendency of prices upward, and the bother of relighting a furnace after the fire has been extinguished, are all among the dreams that have led inventors on from step to step in the hopes that a success could be made from their designs.

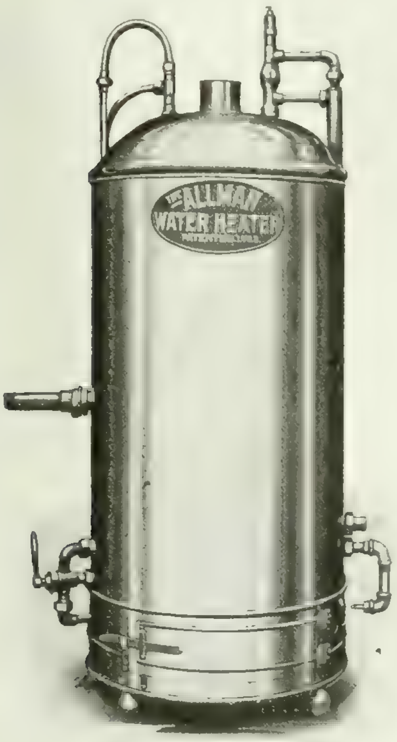

Fig. 1.

In the first attempts that were made much attention was paid to the burners; the idea apparently being to reduce the consumption of gas to a minimum, at the same time securing a maximum output of heat. Then the inventors became bolder, but their attempts did not fill the ideal that was hoped for and the old-fashioned cylindrical gas heater became an installation in many rooms not heated from the furnace; but the results attained were crude. The specifications of a capable gas heater were few, and yet it was many years before even the less complicated features were properly worked out. It was the invention of the automatic water heaters now on the market that contained the original germ of success. In these heaters a circular tube of copper is arranged above a burner supplied with a pilot light. A valve that is controlled by the running water gives entrance to the gas at the burner when a faucet is turned and the escaping gas is ignited by the pilot, with the result that scalding hot water is supplied through the tap. After the water has been turned off the valve closes, the gas is cut from the burner, and all light extinguished excepting the pilot.

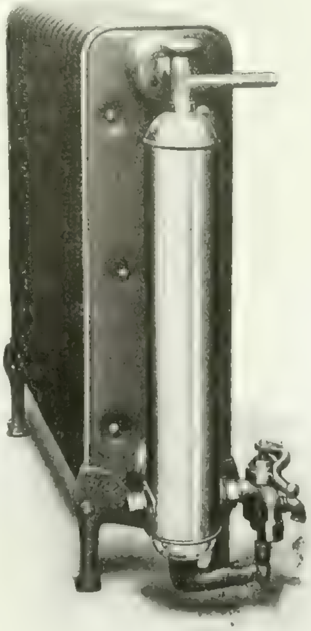

Fig. 2.

There was on exhibit in one of the industrial buildings at the recent Canadian National Exhibition a system of water heating, for house warming, that was the outcome of many years' experimenting, and would appear to have a brilliant future. The system contains a central heater and individual heaters for the radiators. The main heater is shown in Figure 1, and the radiator in Figure 2.

The main heater has many points in common with that described above. One advantage, however, not to be found in the older system is the fact that there are facilities for the storage of thirty gallons of water at a temperature of 150 degrees Fahr. with a consumption of only three cubic feet of gas per hour. This may be used for kitchen, bath or laundry.

The operation of the scheme, put briefly, is as follows: The heater is lighted and water drawn through the radiator until the same becomes warm; then the burner attached to the radiator is lighted and the warm water kept warm. This gives the privilege of using any number of the radiators installed and should it be found convenient to close certain ones the gas consumption is reduced accordingly and the remaining heat confined to the rooms in which the active radiators are operating. The pipes connecting the radiators with the central heater are half-inch in size and the radiators consume four feet of gas per hour each.

The central heater is entirely automatic in all its workings and should either the water or gas be turned off, between the heater and the street, the gas supply is automatically locked and the heater cannot be lighted till the gas has been turned on at the safety valve.

HIGHWAY BRIDGES.

The Illinois State Highway Commission has issued as bulletin No. 9, a 56-page pamphlet entitled, "Modern Bridges for Illinois Highways." The purpose of the bulletin is to encourage the construction of better highway bridges. Better bridges are needed for the traffic of to-day, it is stated, and good bridges are an essential factor towards future road improvement. The bulletin, it is further stated, shows by illustrations the difference between poorly and well constructed bridges, the text having been purposely reduced to a minimum and a relatively large number of illustrations used. These, it is believed, will show clearly the difference between old and modern types of bridges.

The illustrations occupy 41 pages of the bulletin and are accompanied, in most cases, by titles and sub-titles containing much explanatory matter. They show existing bridges of poor design and of correct design and include structures of long and short spans, concrete bridges, steel bridges with both wood and concrete floors, and wooden bridges. Many of the structures shown were built from plans drawn by the State Highway Department. Several of the illustrations show old bridges and the structures which have replaced them. Some of the views show a test bridge built by the Department, and illustrate the tests to which it was subjected.

This test bridge is a reinforced concrete arch having a clear span of 40 ft.; and was built at the Southern Illinois Penitentiary by convict labor and subjected to a number of very severe tests. Heavy loads were placed upon it, each heavier than would be likely to be brought on a bridge or a public highway. In one of these a layer of crushed stone, 12 ins. deep, was spread over the bridge and on top of this cut stone was piled to a depth of 3 ft., making a total unit load of about 300 lbs. per sq. ft., or a total load of 106 tons. Under this the total sag due to the bend in the floor, as well as that in the girders, was ⅛ in. This load was allowed to remain on the bridge for about three weeks, during which there was no increase in the deflection. The original deflection disappeared when the load was removed.

Another test described in the bulletin was made about a year later, when a railroad track was laid on the bridge and a very heavily loaded freight car was run upon it. As the car was somewhat longer than the bridge it was evident that when one truck was placed the centre of the span would produce the maximum bend or sag in the structure. The weight on one truck was found to be 44 tons, and the rails were so cut that they would give no support to the load beyond the length of track occupied by the truck, which was about 8 ft. Thus the total load of 44 tons was applied over an area approximately 5 ft. by 8 ft. Under this load the total deflection, including the sag in the floor as well as that in the girder, was found by careful measurement to be 0.09 in. This deflection disappeared when the load was removed, and six or eight applications of the same load produced the same effect.

During the summer of 1911 another series of tests, more complete than the preceding ones was undertaken, according to the bulletin. Nine brick piers were built beneath the bridge for the purpose of measuring the deflections and the steel reinforcements in the girders and floor was exposed in 15 places to permit determinations of the deformations by means of gauge marks placed on the steel, and bolts were set in the upper part of the concrete girders to determine the deformation in the concrete. A load consisting of 420 tons of crushed stone was placed in eight large bins, and, in addition, 100 tons of pig iron were placed on the west girder and about 60 tons on the east girder. This load produced a total deflection of 1 in. in the west girder and ¾ in. in the east girder without causing failure of the structure. The pig iron was removed within a few days, but the load of 420 tons of stone remained on the bridge for a year, until the present summer. It was then taken off, the deflections being noted as it was removed. When the structure had been completely unloaded it was found to have recovered its original position.

The remainder of the text of the bulletin consists of a general discussion of the economy of well designed bridges of modern types; a detailed presentation of the subject of creosoted timber for bridge floors, and an explanation of the Highway Commission's part in the construction of bridges.

MONTREAL FIRE AND WATER.

The frequent breakdowns in Montreal's water department were discussed by the fire underwriters this week, an increase of rates being considered. Mr. A. W. Hadrill, secretary of the Canadian Fire Underwriters' Association, stated after the meeting that the discussion was the result of the heavy loss at the fire in St. Patrick Street on Sunday night, as no one denied the lack of water had run up the loss. "When we consider that both buildings were fully equipped with fire sprinklers, we feel the fire should have been confined to the rope-walk and that probably would have been the case had there been enough water. The neglect of the water department to have their 15,000,000 gallon pump ready, which was ordered last year, is an instance of the way things are done. We are inclined to believe that the cause for so many accidents is either bad material or bad engineering, or insufficient supervision."

CEMENT DUTY BACK AGAIN.

The five months period in which the duty on cement was reduced by half expired on November 1st. The Government will not extend it. The remission was granted because of the alleged lack of supply in the West and inability, for transportation or other reasons, of the Canadian companies to meet it. The Government's action caused heavy importations from abroad.

During the four months June, July, August and September the importations of cement increased greatly. In these four months of 1911 they were 327,000 barrels, and in those of 1912, they rose to 793,000. The figures by months are:—

Month.	1911. Bbls.	1912. Bbls.
June	55,646	171,395
July	27,314	267,405
August	72,695	188,404
September	171,784	166,452
Totals	327,439	793,656

Significance of these figures will be better understood when the importations into the three prairie provinces are given:—

Month.	1911. Bbls.	1912. Bbls.
June	263	50,434
July	514	140,084
August	187	62,166
September	2,227	49,766
Totals	3,191	302,450

Thus the remission brought the imports up from 3,000 to 300,000 barrels.

RAILROAD EARNINGS.

The following are the railroad earnings for the week ended October 21st:—

	1911.	1912.	Increase or decrease.
C.P.R.	$2,532,000	$2,943,000	+ $411,000
G.T.R.	1,023,892	1,132,152	+ 108,260
C.N.R.	459,000	561,100	+ 102,100
T. & N.O.R.	44,182	27,959	— 16,222

The following are the railroad earnings for the week ended October 31st:—

	1911.	1912.	Increase or decrease.
C.P.R.	$3,675,000	$4,295,000	+ $600,000
G.T.R.	1,463,496	1,648,054	+ 184,558
C.N.R.	794,700	628,500	+ 166,200
T. & N.O.R.	61,285	40,234	— 21,051

The gross earnings of Canadian Pacific Railway last month reached $12,962,000, the largest in the history of the road. The increase over October of last year was $1,847,000. The earnings for the first four months of the company's fiscal year were $48,845,000, which is an increase of $7,498,000 over the corresponding four months of last year.

The statement of the revenue and expenditure of the Intercolonial Railway for the year ended with March 31st, last, shows:—

Passenger traffic, $2,842,810; freight traffic, $6,891,937; mails and express, $428,985; miscellaneous, $430,052; total revenue, $10,593,785. Maintenance of way and structures, $1,812,419; maintenance of equipment, $2,681,543; traffic expenses, $217,943; transportation expenses, $5,630,139; general expenses, $248,990; total working expenses, $10,591,035.

COAST TO COAST.

Toronto, Ont.—It is reported that work will be commenced on the new Union Station for this city early in the coming spring.

Galt, Ont.—Building permits issued in this town during October last have a total value of $80,000. This is 100 per cent. above the same period last year.

Haileybury, Ont.—The Haileybury Board of Trade is opposed to the re-building of the Energite Explosive Foundry here. This is the factory which was destroyed by the explosion in which six persons lost their lives.

Calgary, Alta.—City Commissioner John Chalmers and A. W. Ormsby, of Edmonton, made an examination of the lighting facilities of the city in order that a report might be prepared for the consideration of the Edmonton authorities.

Calgary, Alta.—Figures recently made public by the chief clerk of the electric light department show that the number of users of power for domestic and other purposes from the civic electrical department increased by about 500 during the month of October last.

St. John, N.B.—Mr. W. T. Thorne, president of the Imperial Dry Dock Company, as a director of the proposed steel works for this city has requested the provincial government for aid in the finances of the project. If this work is commenced it is expected that the plant will cost about $3,000,000.

Montreal, Que.—The plants of the Canada Cement Company at the present time are operating on an output of 8,000,000 barrels a year, but with the extensions to present plants and new ones being erected, the company expect by the first of August of next year that there will have been an increase of 50 per cent. in output, bringing the total output for the year to over 12,000,000 barrels.

Province of New Brunswick.—The Transcontinental Railway commissioner has decided in the public interest to operate the completed line of the National Transcontinental Railway in New Brunswick temporarily, or until such time as the G.T.P. has applied for and been granted a lease of this section of the line, under the terms of the National Transcontinental Railway.

Ottawa, Ont.—The Marconi Wireless Telegraph Company, of London, England, have signed a contract with the Canadian Government for the operation and maintenance of nine additional stations on the Great Lakes in Canada. When the stations are completed the company will receive an additional subsidy from the government of $31,500 per annum. The agreement is for nineteen years.

Petrolea, Ont.—At a largely-attended meeting of delegates from various portions of Lambton County of an organization to be known as the Lambton County Good Roads Association, the following were elected officers:—President, Dr. C. O. Fairbank; vice-president, A. D. Arvillee; secretary, A. B. Rocu, and the executive committee will consist of the Reeves of all the municipalities in the county. A grant will be immediately asked for from the county to cover organization expenses. The meeting was addressed by Mr. W. A. McLean, of Toronto, the Provincial Good Roads Engineer.

Oriole, Ont.—The joint campaign committee of the Good Roads Association and Ontario Motor League, at a recent meeting discussed the appointment of a man who would give his whole time to the work of rousing the Ontario public to a realization of the necessity of improving the highways of the province. The board decided to seek for this important position the services of an energetic young man, preferably with newspaper training. In order that as large a number of applications as possible might be received by Mr. George Henry, of Oriole, Ont., the secretary of the Good Roads Association, it was decided to leave the appointment until a subsequent meeting to be held on Friday, November 22nd.

Peterborough, Ont.—That the city may in the near future be defendants in an action for damages instituted by the townships of Otonabee, North Monaghan, and South Monaghan for alleged pollution of the Otonabee River with sewage, was brought out at the meeting of the city council last week. Notice of the issuance of a writ by the legal firm of Peck, Kerr and McEderry on behalf of the said townships, for an injunction restraining the city from polluting the Otonabee River with sewage, and for damages, was submitted for the consideration of the council. On motion of Ald. Johnston and Ald. Anderson, the city solicitor was authorized to appear on this writ within ten days, as after that time plaintiffs would be allowed judgment by default.

Toronto, Ont.—Commissioner R. C. Harris has presented a report, on a proposed Garbage Disposal Plant, to the municipal council. According to the figures submitted the plant will cost $942,000, and the yearly cost of operation will be $298,000 less $224,000, the value of the by-products. Under the plan the commissioner proposes the establishment of four loading stations within the city limits, with incinerators adjacent thereto, at which the garbage is stored in railway cars during the day and removed at night to reduction works, located outside the city limits. The rubbish gathered would be burned at the incinerators near the loading stations, together with a quantity of ashes containing sufficient combustible matter to aid in the destruction of the rubbish, the balance of the ashes to be used for purposes of filling.

Canadian Pacific Railway.—The Canadian Brotherhood of Railroad Employees, claiming to represent 5,000 men on the Canadian Pacific, has for some time been threatening a strike on that road. Last week reports from Winnipeg said that 1,500 of these men, mostly clerks in the freight department, had left their work. They had demanded a large increase of pay. Officers of the road said that the places of the strikers would be filled without much delay. The Minister of Labor, Mr. Crowthers, refused to appoint a board of conciliation, and the railway company not only refused to deal with the representatives of the brotherhood, but announced that it would not nominate a member of the proposed conciliation board. Giving its reasons for its position, the railway company said: "We cannot permit any employees engaged in confidential positions or who have access to the company's correspondence to be a member of any organization, as such would be contrary to the interests of the company. If the employees were permitted to join an organization such as this the records of the company would be confidential no longer. The company from time to time has granted and quite recently granted substantial increases to the above-mentioned class of employees."

Hamilton, Ont.—The municipal council have requested the Dominion Railway Commission to act as arbitrators in the matter of a civic law calling for all electrical companies in Hamilton to bury their wires underground. At a meeting of the board Manager Coleman, of the Hamilton Street Railway Company, testified that it would occasion the Cataract Company a loss of $123,000, and maintained that compensation should be allowed. He was willing that the board's engineer should estimate the extra cost to the company. Chairman Drayton, of the Dominion Railway Board, said it seemed to be felt that the Cataract Company, in estimating the cost, was not merely charging for the work which would be made necessary by the change, but for the improvement of the system. Hon. Adam Beck added that in the estimates the board could take cognizance of the actual expense of going underground only, and not of resultant betterments. Mr. John Markey, for the G.N.W. Telegraph Company, declared that in a municipality of only 80,000 population the revenue derived by the company was insufficient to warrant the change. The gross revenue from outgoing telegraph business in Hamilton was $18,486, and the expenses within the city were $15,147. In addition, the office had to bear its share of charges for everhead wires. The Hamilton office actually stood the company a net loss, and other cities had to assist in paying its deficit. Mr. Edward Beatty, for the C.P.R. Telegraph Company, said his company was not making great objection except on the question of principle. He estimated his company's cost at $12,000.

◆

AN OLD GEORGE WASHINGTON LANDMARK.

The house shown in the accompanying illustration was built by George Washington in 1790—122 years ago. It is located in Glasgow, Barren County, Ky., although when it was built that section was located in Fairfax County, Va. Mr. A. L. Harris now owns and occupies the house.

George Washington, at the time the house was built, owned all that land which now comprises Virginia, Tennessee and Kentucky, it having been granted to him by a greatful American government in consideration for the services rendered during the Revolutionary war.

George Washington built this house as a residence for his cousin, General Spotteswoode, who was governor of Virginia at that time. General Spotteswoode was, by nature, of a very retiring disposition and later became a recluse. He occupied this house until his death, the exact date of which we were unable to learn, and is now buried at Knob Lick, a small hamlet about five miles from Glasgow, Ky.

House Built by George Washington in 1790.

The architecture of the house is a wonderful combination of the frontier's man precaution and the city type of dwelling. The walls are solid brick, 36 inches thick. The floors are of hardwood, two inches thick, made of chestnut and laid with dowel pins. The original roof was hand-drawn chestnut shingles, one-half inch thick and fastened with wooden pegs. There is not a single nail in the entire building, for nails were not manufactured at the time when this house was built.

The windows are of glass that was brought over from France, for glass was not made in America at that time. The wear and tear to which a building is subjected in the course of the years is here given full proof, for this glass is worn so thin that many of the panes are no thicker than an ordinary piece of tissue paper. In late years, light rain storms have at times been sufficient to break out some of the panes.

The portion of the roof shown in the accompanying illustration, is still covered with the original hand-drawn chestnut shingles. A small part of the roof was replaced with a tin roof by Mr. Harris a few years ago. Lately, Mr. Harris has covered the kitchen with J-M asbestos roofing, manufactured by the H. W. Johns-Manville Co., New York.

With the exception of this roofing on the kitchen and the tin roof, the house has not been remodeled during its 122 years existence, and only such minor repairs have been undertaken as were absolutely necessary for its preservation.

◆

CANADA'S PACIFIC COAST ACTIVITIES

With the calling of tenders for the erection of its smelter at Granby Bay, Observatory Inlet, the Granby company is making a start in the practical initiation of a large mining industry in the northern part of the province. Much preliminary work has been done, and much money spent, and it is now proposed to have the smelter in operation inside of another year. It will be able to handle 2,000 tons of ore daily, and will have three copper furnaces, the expenditure to be over $1,500,000. After the copper furnaces are in commission a lead stack will be installed so that custom ores from the Hazelton district can be treated. Already 400 men are employed by the company, which means quite a little town.

Industries are steadily being established on the coast, the operation of which mean much to business and supply men. Close to Vancouver there is the Britannia mine; at Texada Island two or three good mining propositions are being exploited; at Powell River a pulp and paper mill is in operation; at Swanson Bay is another pulp mill; at Ocean Falls, another, along with a large sawmill; mining prospects at Hazelton are bright, while on the Portland Canal the Granby Company will have a mining town of its own.

Although conditions have been reported quiet in Vancouver, figures of different public departments do not show much diminution. Building returns had new records this week; the new Canadian Pacific Railway depot created a record for the largest permit. Just what the Canadian Pacific Railway has in view on the Pacific coast is indicated by what it proposes to do in the way of hotel accommodation in this city. Some time ago plans were submitted to the city building department for a new Vancouver hotel to be eleven stories in height and to cost $800,000. These plans have been cancelled, for it is proposed to make the structure sixteen stories high at a cost of at least a million dollars. Besides these two items just mentioned, there is the Canadian Pacific Railway tunnel under the city to its yards on False Creek. The Canadian Northern Railway has agreed with the city to expend several millions in connection with the improvement of the head of False Creek, the expenditure to be made within a specified time. The Great Northern will spend another million or two. Several other schemes involving large expenditures have been suggested.

Surveys have been begun by the British Columbia Electric Railway Company for a line to be constructed between New Westminster and Port Moody. When this line is built it is hardly probable the construction will stop there, for it would be an easy matter to complete the belt line via Vancouver. The utilization of these routes would give the British Columbia Electric complete control on the lower mainland.

United States capital is seizing opportunities in the northern interior in the way of colonization possibilities, and the latest deal is an immense one. Mr. Lauchlin Maclean, of Spokane, and associates have bought 550,000 acres for $2,730,000. The question might be raised, though, if the acquisition of these large areas by syndicates might not be a cause in discouraging the bona fide settler who wants land as cheap as he can get it, as otherwise he cannot afford to pay two or three profits.

HIGHWAY ENGINEERING COURSE IN COLUMBIA UNIVERSITY.

The following non-resident lecturers in highway engineering at Columbia University have been appointed for the 1912-1913 session: John A. Bensel, New York State engineer; William H. Connell, chief, Bureau of Highways and Street Cleaning, Philadelphia; Morris L. Cook, director, Department of Public Works, Philadelphia; C. A. Crane, secretary, the General Contractors' Association; W. W. Crosby, chief engineer to the Maryland Geological Survey and consulting engineer, Baltimore; Charles Henry Davis, president, National Highways Association; A. W. Dow, chemical and consulting paving engineer, New York City; Walter H. Fulweiler, engineer, research department, United Gas Improvement Company; John M. Goodell, editor-in-chief, Engineering Record; D. L. Hough, president, The United Engineering and Contracting Company; Arthur N. Johnson, state highway engineer of Illinois; Nelson P. Lewis, chief engineer, Board of Estimate and Apportionment, New York City; J. C. Nagle, professor of civil engineering and dean of the School of Engineering, Agricultural and Mechanical College of Texas; Harold Parker, first vice-president, Hassam Paving Company; H. B. Pullar, assistant manager and chief chemist, American Asphaltum and Rubber Company; J. M. F. de Pulligny, ingenieur en chef des ponts et chaussees, et Directur, Mission Francaise d'Ingenieurs aux Etats-Unis; John R. Rablin, chief engineer, Massachusetts Metropolitan Park Commission; Clifford Richardson, consulting engineer, New York City; Philip P. Sharples, chief chemist, Barrett Manufacturing Company; Francis P. Smith, chemical and consulting paving engineer, New York City; Albert Sommer, consulting chemist, Philadelphia; George W. Tillson, consulting engineer to the president of the borough of Brooklyn.

REGINA ENGINEERING SOCIETY.

About sixty members of the Regina Engineering Society and their friends sat down to the second annual dinner in the cafe of the Parliament Buildings on the evening of November 7th.

The event was a complete success and it is probable, as was suggested by the president, A. J. McPherson, that the dinners will be given oftener than once a year in future.

The president's response to the toast "The Engineering Society," was filled with suggestions of future policy. He touched on the need of a home for the society, and advanced his suggestion of a club with the members of the Engineering Society in the majority.

◆

Some months ago there appeared an article in *The Canadian Engineer* dealing with a sun power plant, the invention of Mr. Frank Shuman, of Philadelphia. Word has been received from Zeitoun, Egypt, which states that one of these plants is installed at Meadi, a suburb of Cairo, and is pumping water with complete satisfaction.

PERSONAL.

MR. M. B. HASTINGS, until recently with the Toronto Hydro-Electric system, has accepted a position with A. H. Winter Joyner, Limited, Toronto, as sales engineer.

COLONEL CLOUGH, formerly assistant superintendent of Halifax and St. John district of the Intercolonial Railway, has been appointed assistant to General Superintendent F. P. Brady.

MR. T. KENNARD THOMSON, C.E., consulting engineer, of New York, addressed the Canadian Club of Niagara Falls, Ont., on Thursday, November 7th, on "Bridges of the Past and Future."

MR. W. A. STEWART, of Cornwall, late superintendent of operation, St. Lawrence Canals, has been appointed superintendent of works for Mr. D. R. McDonald, on his harbor contract at St. John, N.B.

MR. M. R. SHAW, a graduate of the Faculty of Applied Science, Toronto University, of the class of '09, has been appointed to a research fellowship, the funds for which have been raised by the Engineering Alumni Association of the University.

MR. PAUL SEUROT, M.Can.Soc.C.E., M.Am.Soc.C.E., of Montreal, Que., has been awarded a Telford premium of the Institution of Civil Engineers of Great Britain for a paper published in the "Proceedings" of the society during the 1911-1912 session.

PROF. C. A. ZAVITZ, of the reforestation station in Norfolk county and lecturer at the Ontario Agricultural College at Guelph, has been appointed provincial forester by the Ontario Government. This appointment, in all likelihood, means the establishment of a forestry branch in connection with the Department of Lands, Forests and Mines with Prof. Zavitz as its head.

MR. A. CHAUSSE, chief building inspector of Montreal, is attending the convention of the American Society of Municipal Improvements as a delegate from Montreal. He will call on the return journey at Detroit, Chicago, St. Louis and Kansas City to study matters in connection with the administration of building departments and with building operations in those cities.

MR. CHARLES H. BIGELOW has accepted the position of chief mechanical engineer of the Millville Manufacturing Company, Millville, N.J. Mr. Bigelow recently returned from St. Catharines, Ont., where he had charge of the construction of a factory which will handle the Canadian business of the Yale and Towne Manufacturing Company, Stamford, Conn.

MR. DONALD MALCOLM McINTYRE, K.C., of Kingston, has been appointed chairman of the Ontario Railway and Municipal Board to succeed the Hon. James Leitch, who was recently appointed to the high court bench. The announcement of this appointment was made by Sir James Whitney recently. Mr. McIntyre will assume the chairmanship in the near future.

MR. J. A. MacMURCHY, of the Class '96 Faculty of Applied Science, University of Toronto, chief draughtsman to the Westinghouse Machine Company, of Pittsburg, will address the Engineering Society of the University of Toronto on Friday afternoon, November 15th, at 4.30 p.m., on "The Development of a Reaction Steam Turbine." His address will include explanatory notes on practical methods employed in this manufacturing plant. The meeting will be held in the Chemistry and Mining Building.

NATIONAL ASSOCIATION OF CEMENT USERS.

The ninth annual convention of the National Association of Cement Users will be held in Pittsburgh, Pa., December 10-14, inclusive. The convention proper will open on Tuesday evening, December 10, and will close on Friday evening, December 13. The sessions and headquarters of the convention will be at the Fort Pitt Hotel. In view of the numerous suggestions received to that effect, the convention period has been reduced over those of former years by two days, and in order that an equal amount of work may be accomplished, afternoon sessions will be held. No session will be held on the evening of the opening of the Cement Show in order that members may be afforded the opportunity to attend the same. The annual banquet will be held on Thursday evening.

◆

COMING MEETINGS.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Annual Convention to be held at Dallas, Texas, November 12th to 15th, 1912. Secretary, A. P. Folwell, 50 Union Square, New York.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. Saturday Evening Lecture, Nov. 23rd, at 8 o'clock. "The Prevention of Sewage Pollution relative to Water Supply," by T. Aird Murray, C. E., Toronto. Secretary, J. Patterson.

NATIONAL ASSOCIATION OF CEMENT USERS.—December 12th to 18th. Annual Convention, Pittsburgh. Pa. President R. L. Humphrey, Harrison Building, Philadelphia, Pa.

AMERICAN CIVIC ASSOCIATION.—Annual Convention will be held at Baltimore, Md., November 19th to 22nd. Secretary, Richard B. Watrour, Union Trust Building, Washington, D.C.

AMERICAN RAILWAY ASSOCIATION.—Nov. 20th. Annual Meeting at Chicago, Ill. Secretary, W. F. Allen, 75 Church St., New York.

UNION OF MANITOBA MUNICIPALITIES.—Programme for Ninth Annual Convention to be held in Convention Hall of the Industrial Bureau, Winnipeg, Nov. 26, 27, 28, 1912. Secretary, Reeve Cardale, Oak River, Man.

AMERICAN WOOD PRESERVERS' ASSOCIATION.—Ninth Annual Convention will be held at Chicago. Jan. 21-23, 1913. Secy-Treasurer, F. J. Angier, Mount Royal Station, B. & O. R. R., Baltimore, Md.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. Secretary, E. L. Power, 150 Nassau St., New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

◆

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh B. Fergusson, 911 Rogers Building, Vancouver, B.C. Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P O Box 1290

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES. President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION. President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.: Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor, Secretary-Treasurer Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President Dr. A. E. Barlow, Montreal; Secretary. H. Mortimer Lamb, Windsor Hotel Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr, G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—*Secretary*, J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

TENDERS PENDING.

In Addition to Those in this Issue.

◆

TENDERS.

Halifax, N.S.—Tenders will be received until noon of November 14th, 1912, for the construction in permanent materials, of bridges, culverts, etc., required on road, Baddeck to Hunter's Mountain, County of Victoria. Plans, etc., at the office of the Road Commissioner, Halifax; John G. Morrison, Englishtown; George McRae, Baddeck; A. A. Buchanan, M.P.P., Neil's Harbor. E. H. Armstrong, Commissioner Public Works and Mines, Halifax, N.S.

Humboldt, Sask.—Tenders will be received until November 21st, 1912, by W. H. Stiles, secretary-treasurer, for the following works:

Contract "B"—Power House.
Contract "H"—Two Return Tubular Boilers.
Contract "J"—High Speed Steam Engine.
Contract "K"—Electric Lighting System.

Plans and specifications may be seen at the office of Messrs. Chipman & Power, Engineers, Winnipeg and Toronto; and at the town hall, Humboldt. O. W. Anderson, Esq., Mayor.

Kamloops, B.C.—Competitive plans are invited for the laying out of Riverside Park. The best plan, if selected, will be awarded an honorarium of $200. Plans to be in by December 16th, 1912. J. J. Carment, City Clerk.

Montreal, P.Q.—The Central Railway Company of Canada invites tenders for supplying railway ties in lots of five to one hundred thousand. Tenders to be received until noon of December 20th, 1912. F. Stuart Williamson, Chief Engineer, 44 Beaver Hall Hill, Montreal.

Ottawa, Ont.—J. G. Desbarates, Deputy Minister of the Naval Service, Department of Naval Service, will receive tenders up to noon of December 3rd, 1912, for the following metal naval stores: Brass and copper sheets, bars and tubes, zinc and lead sheets, steel plates, sheets, angles and bars, steel wire ripe, colder, spelter and tin, babbit metal, copper and steel nails, steel files. All for delivery at H.M.C. dockyards at Halifax, N.S., and Esquimalt, B.C. Full particulars may be obtained from the Naval Store Officer at either dockyard, or at the office of the Deputy-Minister.

Ottawa, Ont.—Tenders for the construction of two gasoline launches for the Fishery Patrol Service, in the Province of British Columbia, will be received until November 20th, 1912. Plans, etc., can be obtained upon application from the Chief Inspector of Fisheries at New Westminster, Inspector of Fisheries at Nanaimo, E. B. Schook, Vancouver, and from the agent of the Department at Victoria, B.C. Alex. Johnston, Deputy Minister of Marine and Fisheries, Department of Marine and Fisheries, Ottawa.

Peterborough, Ont.—Tenders addressed to R. C. Desrochers, Secretary, Department of Public Works, Ottawa, until November 20th, 1912, for interior post-office fittings. Plant, etc., at the office of Mr. F. Bartlett, Architect, Peterborough, Ont.; Mr. T. A. Hastings, Clerk of Works, Postal Station F., Toronto, and the Department of Public Works, Ottawa.

Three Rivers, Que.—Tenders for the construction of a public building will be received until November 25th, 1912, at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa. (See Advt. in The Canadian Engineer.)

Toronto, Ont.—Tenders addressed to W. C. Wilkinson, Secretary-Treasurer, Board of Education, will be received until noon of Friday, November 15th, 1912, for the several trades required in the erection of a new school building on Pauline Avenue. Specifications, etc., at the office of the Superintendent of Buildings, City Hall, Toronto.

Toronto, Ont.—Tenders will be received by the Chairman of the Board of Control, City Hall, Toronto, until Tuesday, November 19th, 1912, for the construction of a number of sewers on different streets. Specifications, etc., at the office of the Sewer Branch, Department of Works, City Hall, Toronto. H. C. Hocken, (Mayor), Chairman of the Board of Control.

Winnipeg, Man.—Tenders addressed to the Chairman, Board of Control, will be received until November 20th, 1912, for the following machinery for the machine shop at the city yards, Ross Avenue:—

1 Double-backed Geared Gap Lathe. Gap 60-in. by 3-ft. long. Lathe 12-ft. 6-in. between centres. Fitted with A. C. Motor.

1 Single Jaw Punch and Shear fitted with A. C. Motor.

1 Five ft. Radical Drill, fitted with A. C. Motor.

Specifications, etc., at the office of the City Engineer, 223 James Ave. M. Peterson, Secretary, Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders for the supply and installation of turbine pumps and motors required for the extension of the artesian well water supply system of the city of Winnipeg, will be received until November 29th, 1912. Specifications, etc., at the office of the City Engineer, 223 James Ave. M. Peterson, Secretary, Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders addressed to the chairman, Board of Control, will be received at the office of M. Peterson, Secretary, Board of Control Office, until November 22nd, 1912, for the supply of 600 manhole grates in accordance with plan and specification, copies of which may be obtained at the office of the City Engineer.

◆

CONTRACTS AWARDED.

Arrowhead, B.C.—The contract for the lockup has been let to Mr. Harry Fraser, at a price of $1,750.

Brantford, Ont.—The Hydro-Electric Power Commission have awarded a contract to Messrs. Bennett & Bordon, of Brantford, for the erection of the substructure of the Brant transformer station.

Brockville, Ont.—Timber superstructure of wharf, on part of Tunnel Bay Dock. Contractors, Messrs. C. L. McCool and Thos. H. Moffat, of Pembroke, Ont., at unit prices involving an amount of $15,382.75.

Goderich, Ont.—Mr. Wm. Bermingham, of Goderich, has received the contract for the construction of a breakwater, at a contract price of $26,000, on amended plans and specifications.

Guelph, Ont.—At a meeting of the Light and Heat Commission, the contract for the cement and brick work of their new building was let to Messrs. Johnston and Williams, at $2,350. The carpenter work will be done by the Commission themselves, and tenders will be asked for the supply of lumber.

Massett, Queen Charlotte Island, B.C.—Construction of pile wharf. Contractor, W. G. Gillett, Esq., of Vancouver, B.C., at $4,875.

New Westminster, B.C.—The following contracts have been awarded:—

District A, B and "Cutfall" in Sec. No. 2, of the Sapperton District, the construction of about 7¾ miles of combined sewers, contractors: "A" The North West Municipal Construction Company, of New Westminster, at $41,283.00; "B," The Powers Contracting Company, of New Westminster, at $30,270.00; and "Outfall," T. R. Nickson, of Vancouver, at $44,237.00, for reinforced concrete lock joint pipe construction.

Supply of 10,400 feet of reinforced concrete pipe, in Dist. "A," "B" and "Outfall," of Section No. 2. The Pacific Lock Joint Pipe Company, of Seattle, $44,557 and Mr. M. P. [illegible]

Red Deer, Alta.—Messrs Borton and Willets, of Spokane, Wash., have received the contract for the erection of the new Merchants Bank building.

Toronto, Ont.—Mr. Gordon Perry, manager of the National Iron Works Company, has awarded a contract to Mr. John E. Russel for new buildings for extension to their cast-iron pipe foundry at Ashbridge's Bay. The new buildings will more than double the capacity of their plant, and the total cost will approximate $300,000. Work will be started at once.

Victoria, B.C.—The contract for the kitchen and laundry machinery for the Mental Hospital at Coquitlam has been awarded by the Minister of Public Works, to Messrs. McLennan, McFeely and Co., of Vancouver, at a price of $8,753.30.

◆

RAILWAYS—STEAM AND ELECTRIC.

Calgary, Alta.—Mr. McCauley, superintendent of the street railway, has proposed that a line of motor busses be established as an extension to the existing lines now under operation. The suggestion has been viewed with favor by the commissioners, but no definite decision has been arrived at.

Central Railway.—An officer writes that a contract has been given to C. J. Wills & Sons, Montreal, Que., for work on this line. The plans call for building from Montreal, via Hawksbury, Ottawa, Carleton Place, Bannockburn, Fenelon Falls and Orillia to a point on Georgian Bay, about 340 miles. Track has been laid on about 60 miles. The company expects to develop a traffic in grain, lumber, minerals, general country produce and manufactured goods. William Owen, president, C. N. Armstrong, vice-president and managing director, and F. Stuart Williamson, chief engineer, 44 Beaver Hall Hill, Montreal.

Vancouver, B.C.—The British Columbia Electric Railway Company have installed five new cars on their line between this city and New Westminster.

Winnipeg, Man.—The Winnipeg, Selkirk and Lake Winnipeg Electric Railway have started construction work on an extension of their line in a westerly direction to the base of Stony Mountain. Wilford Phillips, chief engineer.

◆

LIGHT, HEAT AND POWER.

Chatham, Ont.—Negotiations are now pending for the transfer of the C. W. and L. E. Electric Railway, and it is understood that a bond of $50,000 has been put up as an evidence of good faith, in the deal. The new owners will likely extend the road from Erie Beach to the Eau and from Wallaceburg to Sarnia.

Merritton, Ont.—A number of the old street lamps are to be replaced with new ones. Richard Clark, Town Clerk.

Nelson, B.C.—If a by-law, introduced by Ald. Walley, chairman of the Fire, Water and Light Committee, becomes active, small consumers of electric power from the municipality will have their rates reduced by 15 per cent.

St. Boniface, Man.—The management of the Winnipeg Electric Company tendered a rate of 1 cent per kw.h. for power to be used in the new pumping station on Plunket Street for a term of five years. The town council objected to the term of five years and notified the company that they must reduce it to two years or the negotiations would be cancelled.

Welland, Ont.—The town council has instructed the Hydro-Electric Commission to install a lighting plant for this municipality. The cost of this work will be about $95,000.00.

◆

GARBAGE, SEWAGE AND WATER.

Toronto, Ont.—Mr. R. C. Harris, Commissioner of Works, has presented an estimate of costs regarding the installation of mechanical filters to safeguard water users in sections of this city recently annexed. In his report he states that the cost would be about $56,000 for a pumpage of 2,500,000 gallons per day.

◆

BUILDINGS AND INDUSTRIAL WORKS.

Brantford, Ont.—The Pratt and Letchworth Company of this city, which employs 500 hands in the manufacture of malleable iron castings, has been acquired by the Canadian Car and Foundry Company, of Montreal.

Hamilton, Ont.—Mr. T. J. Stewart, M.P., has received a communication from the Department of Public Works, Ottawa, which would indicate that work on the harbor of this city would be commenced in the immediate future. The letter states that the matter of calling tenders is well under way.

Hamilton, Ont.—The Board of Education are considering the matter of building an addition to the Barton Street School. Mr. Foster is the secretary of this Board.

Lethbridge, Alta.—A report states that the management of the McClary Company are considering the matter of erecting a warehouse in this city. At the present time the Stafford-Agnew Hardware Company are distributing agents for the McClary interests.

Moose Jaw, Sask.—Mr. W. L. Brackett is taking steps to interest a number of business men of this city in a scheme calling for the erection of a 300-roomed hotel.

Money Point, N.S.—It is reported that the government will rebuild the fog alarm station at this point.

Tarvia

Preserves Roads
Prevents Dust~

Section of Government Parkway, Ottawa, Canada, treated with Tarvia B.

The Property Owners' Investigation.

IN the City of St. Thomas, Ont., the property owners on Gladstone Avenue contemplated petitioning the City Council to improve the roadways. They commissioned one of their number to visit various American cities, inspect pavements and make a report. Their investigator, Mr. E. A. Horton, visited various cities in New York and New Jersey. In his report he made the following statements:

> "I saw a 'Tarvia X' road in Rochester which extends from the city to the lake front, a distance of about six miles It had been in use for eighteen months, and when I saw it, it was in excellent condition, with heavy traffic over it every day. I........inspected a piece of road in Newark........the surface when finished was smooth, and to my mind was one of the finest pieces of road it was my privilege to see. We then inspected another piece of 'Tarvia X' which had been done by the Road Commission two years ago........Constant heavy traffic passes over this road every day, and trucks have loads of from 6 to 8 tons. Steel-tired drays were used with most of their heavy traffic. This piece of road, as I saw it, did not show any wear whatever, and was apparently in as good condition as when it was put down.
>
> "I did not confine my attention to Tarvia roads as I saw (here he mentioned five of the commonest types of road treatment) and every other kind of road that is known.
>
> "I must say after making enquiries from people who were in no way interested, nor did they know I was seeking information, that everyone had a good word to say for the Tarvia road. I have no hesitation in recommending it for use on our street, and at the estimate cost that has been given us, after seeing the many pieces of road that I have seen, I think it is the cheapest road that can be built."

The foregoing is quoted from the St. Thomas, Ont., Journal of February 20th, 1912. Since that date Gladstone Avenue has been constructed with Tarvia X.

Anyone who will investigate the road problem with the same thoroughness will reach similar conclusions. Tarvia is made in three grades:

"Tarvia X" for use in constructing roads and pavements.

"Tarvia A" for hot surface applications.

"Tarvia B" (applied cold) for dust prevention and road preservation.

Booklet describing the latest developments in methods for building tarviated roadways and pavements will be sent free on request. Address our nearest office.

THE PATERSON MANUFACTURING COMPANY, LIMITED
MONTREAL TORONTO WINNIPEG VANCOUVER
THE CARRITTE-PATERSON MANUFACTURING CO., LIMITED
ST. JOHN, N.B. HALIFAX, N.S.

Montreal, P.Q.—Following a recent purchase by Messrs. George Marcil & Company, a report states that a ten-story building will be erected on the site within the next few months.

Regina, Sask.—The municipal council are preparing estimates and making preliminary preparations for the erection of a new police station. Mr. E. B. Fulton is acting as architect in the matter and Mr. Zeats is chief of police.

Stratford, Ont.—Mr. Hennicke, formerly of the Hard Manufacturing Company, Buffalo, N.Y., is interested in a new concern starting in this city for the manufacture of brass beds. The company have secured temporary quarters in the Kemp Building and will, in all probability, erect a structure for their own use next summer.

Toronto, Ont.—The directors of the Fred Victor Mission are planning to erect a new hall at a cost of $50,000.

Vancouver, B.C.—The directors of the Granby Consolidated Mining, Smelting and Power Company will erect a new smelter at Granby Bay, Observation Inlet, Portland Canal district. Mr. F. M. Sylvester, acting general manager.

Vancouver, B.C.—According to plans filed by the Canadian Pacific Railway, the new hotel for this city will be 16 stories instead of 11. This will increase the estimated cost of erection by $400,000.

Windsor, Ont.—The directors of the Young Men's Christian Association will erect a $70,000 building in this city.

Winnipeg, Man.—Mr. E. A. Taylor, 26 Guelph Avenue, Toronto, is interested in a projected company that is forming for the manufacture of stained glass windows in this city.

◆

BRIDGES, ROADS AND PAVEMENTS.

Edmonton, Alta.—A demonstration was recently made by the directors of the Nakamun Asphalt and Oil Company to show the qualities of their asphalt for street paving in Western Canadian cities.

Fredericton, N.B.—The provincial board of works will erect a $300,000 bridge at St. John.

Nelson, B.C.—The new bridge to be erected across the Taghum River at this point will consist of three steel spans, each 170 feet in length, supported on three thirty-foot concrete towers. The cost of this work is placed at $100,000. J. P. Ford, resident provincial public works engineer.

St. Boniface, Man.—The ratepayers voted in favor of spending the sum of $400,000 on the erection of a new bridge over the Red River at the head of Provencher Street. J. B. Cote, town clerk.

Toronto, Ont.—The Municipal Council passed a by-law calling for the erection of six bridges at a cost of $[illegible]. The [illegible] are as follows:—

Crawford Street	$29,450 00
[illegible] Avenue	58,000 00
[illegible] (foot bridge)	12,000 00
[illegible] Street	[illegible] 00
[illegible] Road	14,118 00
[illegible] Street	11,800 00

R. C. Harris, Commissioner of Works.

Walkerton, Ont.—The engineering department of the Canadian Pacific Railway will erect a bridge at this point at a cost of $[illegible].

◆

CURRENT NEWS.

Berlin, Ont.—The mayor and council of this city have had preliminary estimates of the cost of a new city hall prepared. The report is now to hand and calls for an expenditure of $[illegible].

Montreal, P.Q.—The failure of the water supply is causing considerable inconvenience to the hospitals.

Ottawa, Ont.—The number of claims for compensation arising from the recent typhoid epidemic now number [illegible].

Preston, Ont.—The management of the Anchor Bedding Company have asked certain inducements prior to their decision to erect a factory at this point. The ratepayers will [illegible] November 18th.

Port Alberni, B.C.—The municipal council will receive applications for the position of City Engineer up to November 26th next. Each applicant to state age, experience, salary expected, and when he could come. All letters in this matter to be addressed to the council and marked "Engineer."

Sarnia, Ont.—The ratepayers carried the water works by-law calling for the expenditure of $500,000. H. A. McLean, Town Engineer.

Saskatoon, Sask.—The municipal Board of Trade are taking an active interest in the matter of a public library, and if their present plans are adopted the city will have a fine building.

St. Boniface, Man.—Tenders for the supply of an electric motor for pumping purposes were received from the following firms:—Heath and Thomas, Canadian Foundry, Drummond and McCall Company, Goldie Engine and Supply Company, Canada Traders, Ltd., Dominion Equipment and Supply Company, Stuart Machinery Co., Skinner and Co., John McDougall and Co., Chapman and Walker and Escher, Wyss and Co. The prices varied from $1,943.40 to $2,000. The award has not yet been made public.

Sydney, C.B., N.S.—The following is tonnage of the products of the Dominion Iron and Steel Company for the month of October last:

Coke	50,540
Pig-iron	31,090
Steel ingots	29,075
Steel blooms	27,880
Rails	[illegible]
Rods	[illegible]

Victoria, B.C.—The management of the Victoria Opera House Company state that the plans for their new building will be sufficiently completed in a few weeks to allow of tenders being called and contracts awarded. This structure is to be built entirely of Canadian materials.

◆

NEW CONCRETE COMPANY TO LOCATE IN MOOSE JAW, SASK.

Samples of the products of the Shope Concrete Products Co., of Portland, Oregon, who will locate their factory in Moose Jaw, have been received by the Board of Trade. The bricks and tiles are in different shades, and the most striking feature in connection with them is their light weight. Their lightness does not, however, deteriorate from their strength or durability, as engineering tests have demonstrated. The brick is made in a patent process in which sand is largely used, and it only requires 24 hours to make a brick. The new concern will employ 50 men at the outset, and it is possible for each man to daily turn out 2,000 bricks.

◆

POWER SPRAYERS.

The Gould, Shaply and Muir Company, Limited, Brantford, Ont., are manufacturing a power sprayer under the trade name of "The Ideal." The engine is of 2½-h.p., and keeps cool with a couple of pails of water. The water jacket surrounds the cylinder and extends above it with opening on top for filling. The water jacket can be easily filled or drained in a moments time. The speed of the engine can be instantly changed to run fast or slow as desired and is controlled by hit and miss governor. This engine is built on the 4 cycle principle, the same as our horizontal style, and is very economical in the consumption of fuel.

The pump has large water ways which permit all gritty particles to pass through valves. The glands and followers, valves, valve caps and seats are all made of bronze. The plungers are outside packed and easy to get at. The valves can be readily reached by removing the valve covers. The air chamber is large and enables a uniform high pressure to be maintained. Discharge openings are provided on each side of the air chamber and will supply two leads of hose with two or more nozzles each. The pump is run by means of a rocker arm attached to the pump gear. This outfit includes, pressure gauge, water relief valve, 10-ft. of rubber suction hose, 1 strainer 3¼-in. in diameter, two 25-ft. lengths of ⅜-in. discharge hose and couplings, 2 brass Y connections, 4 "Mistry Jr." nozzles, 2 bamboo poles 8-ft. and 10-ft., 1 brass Y discharge and shut off, so that both discharges may be opened or closed at will.

DEPT. OF RAILWAYS AND CANALS, WELLAND

Superintending Engineer's Office.
Messrs. Wettlaufer Bros., St. Catharines, Feb. 7th, 1912.
No. 178 Spadina Ave., Toronto.

Dear Sirs :—Replying to yours of the 6th, I beg to say that the two Mixers received from you last summer proved to be very handy, useful machines. They turned out excellent concrete and we had no trouble with them at all.

Yours truly, J. L. WELLER, Superintending Engineer.

CANADIAN NORTHERN RAILWAY

Belleville, Ont., Feb. 14th, 1912.
Wettlaufer Bros.,
178 Spadina Ave., Toronto, Ont.

Dear Sirs :—I think it is my duty to inform you that I am entirely satisfied with the two Concrete Mixers purchased from you last season. I have tested them in every way possible, and in every case I have found them capable of doing first-class work. Yours sincerely, J. O. GIROUX.

We have manufactured concrete mixers and concrete machinery of all kinds for many years; also previously had taken contracts for concrete work of all kinds, and have had the actual experience of just what a concrete mixer should do. Wettlaufer Mixers are perfect to-day through the help of the hundreds of contractors who purchased Wettlaufer Mixers in past years. We have gone personally to them and watched these machines working on all classes of work, asked the contractors their opinions, and so have evolved the present perfect mixer.

Compare the thoroughness, simplicity and durability of our mixer with other makes. The Wettlaufer Mixer is of the heart-shaped drum type; this means quick and positive mixing and the saving of power.

ADAMS-HYDRAULICS, LIMITED.

The Adams-Hydraulics, Ltd., 7 Old Queen Street, Westminster, S.W., have forwarded a list of the manufactures they specialize in. The following covers the full list:—

Air compressors and "Adamic" distributors. "Adamics" fittings.

Bacteria bed apparatus, basement drainers, back pressure valve, bell mouth outlets, bucket bridges, bucket pump.

Cast iron pipes, castings, centrifugal pumps, chain pumps, covers, "Cresset" distributors.

Decanting valves, distributors, drinking fountains.

Ejectors, engines.

Filters, filter presses, flush tank syphons, flap valves, flushing syphons, floating arms.

Gulley grates.

Hydrants, hydraulic machinery.

Manhole covers, motors, mechanical rakes, motor power ejectors.

Overflow weirs.

Pressure regulating pumps, penstocks, pressure filters, petrol engines, pressure reducing valves.

Rams, reflux valves, reservoir fittings, recorders, revolving discs.

Screens, sewage disposal appliances, sewage ejectors, sewage lifts, sewer flushing syphons, stand pipes, sludge elevators.

Tanks, turbine pumps, turbine regulators, trench pumps, telescopic weirs.

Valves, vacuum pumps, vent columns.

Water filters, water mains, water softening plant, water wheels, water works supplies, wind engine pumps.

◆

THE OLIN GAS ENGINE COMPANY.

The above company, of Buffalo, N.Y., U.S.A., have commenced the manufacture of a gas engine known as the "Olin engine." They are made in sizes varying from 6½ to 40 horse-power under the following specifications:—

Frame is of graceful design, heavily trussed on under side and very rigid.

Cylinder is of special fine grained iron, accurately bored and is bolted and dowel pinned to frame; has ample water space and means for readily cleaning same.

Cylinder head is separate from the cylinder and is water jacketed.

Valve chamber bolts to frame, is water jacketed, and carries exhaust valve.

Valve chamber cap carries fuel valve and main inlet valve.

Valves are of the poppet type and are amply supported by stems in long bearings.

Wheels are carefully proportioned and counterbalanced and are turned crowning.

Crankshaft is exceptionally heavy and is cut from solid forging of 28 point open hearth steel. It is finely machined and has finished throws.

Connecting rod is of marine type, carefully designed and machined.

Piston is of exceptional length and fitted with rings which are made eccentric and finished under tension.

Main bearings are lined with high grade babbitt. The crank bearing is of bronze lined with high grade babbitt.

Igniter is of the hammer break type having points tipped with platinum; wearing surfaces are exceptionally large.

Governor of the hit and miss type acts by holding the exhaust valve open and fuel valve closed when the charge is not needed to keep up the speed. A hand wheel is provided for regulating the speed while engine is in motion. A relief cam provides for throwing off the compression when starting the engine.

Governor of the throttling type acts by varying the quantity of both the gas and air according to the load.

Gasoline equipment is of simple, efficient and approved design. It has hand priming pump and double valves.

Fly wheels, rims and hubs, shaft cap, crank throws, cylinder head, valve stems, rods, governor and brass fittings are polished.

Cast surfaces are filled, rubbed and coated with several coats of enamel.

Standard gas engine equipment consists of gasometer, muffler, lubricators, oil guard, gas index cock, shaft cap, standard pulley, piston wrench, electric igniter, batteries and spark coil.

Standard gasoline engine equipment consists of muffler, lubricators, oil guard, shaft cap, standard pulley, piston wrench, gasoline attachment, electric igniter, batteries and spark coil.

Five large Edison type batteries are furnished.

Mr. Marshall Armstrong, Hagersville, Ont., is the Canadian representative.

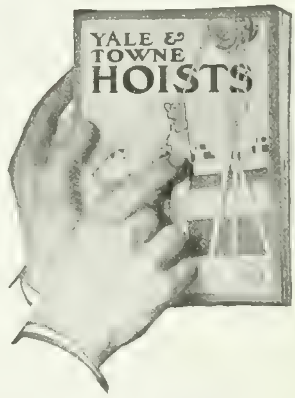
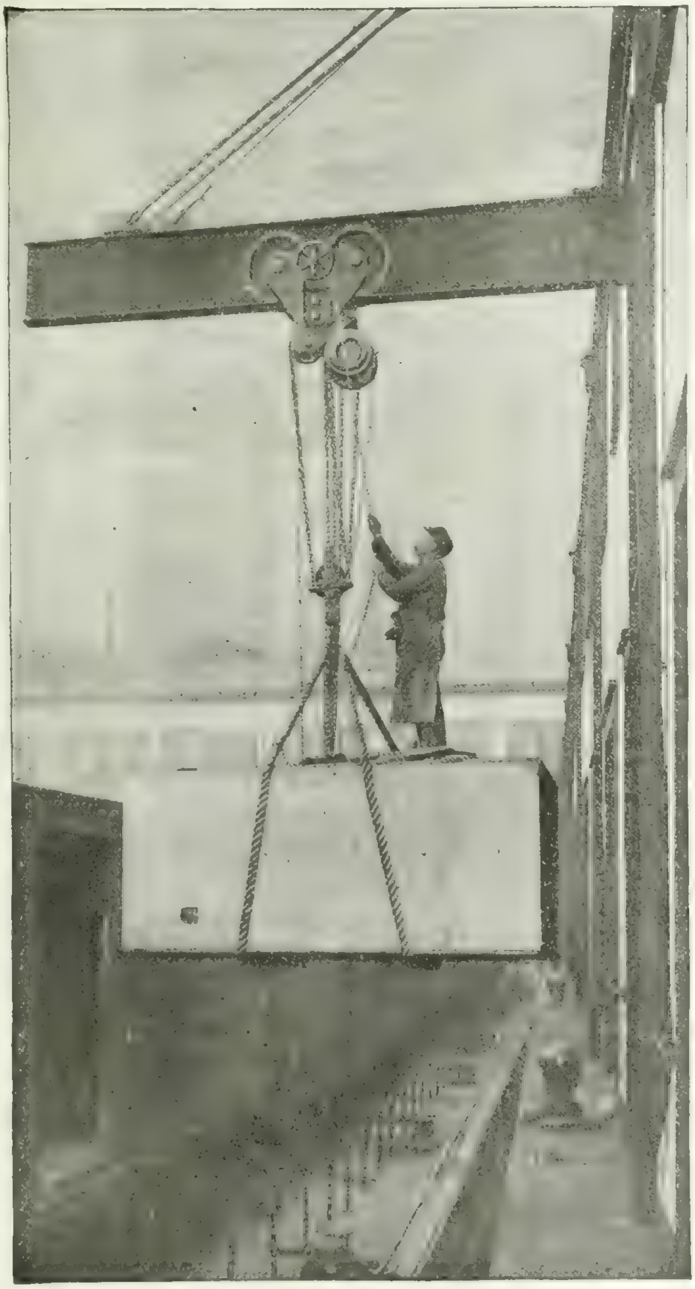
COPY OF ENGINEER WANTED.

One copy of our issue of July 11th last, is required. The person forwarding the same to this office will have his subscription extended one month.

THE TRIPLEX BLOCK

REASONS FOR SENDING TODAY FOR THIS BOOK.





Triplex Block built into a 10 ton geared trolley and used for loading on floats lying alongside a pier in New York City.

A Book on the Handling of Load, the Latest Practice Here and Abroad.

The change is coming fast. Modern plants today are equipping throughout to give each workman easy mastery over any load up to 20,000 lbs.

The new practice is to reduce all loads to one-man manageable loads, from the raw material coming in to the completed material going out. This frees the factory from an enormous waste. The primitive way of pitting time-paid muscle against stubborn weight, soon costs any manufacturer who stands for it a fortune in wages and restricts his output.

Months of research were spent by Yale and Towne engineers to make this book cover a wide range of conditions, so the man who sends for it will find it the most practical and helpful book that ever came to his desk.

Send for a free copy now, before the thought is out of your mind.

Triplex Blocks { **16 Sizes:** One-fourth of a ton to forty tons.
9 Active Stocks all over Canada.

Every Block Tested to Fifty Per Cent. Overload.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

17869—October [illegible]—Directing C.P.R. to construct spur from main line east of Neebing Ave., Fort William, Ont., to a point 100 feet south of C.N.R. passing under C.N.R. by means of subways; and directing C.N.R. at its own expense, to raise its railway at least [illegible] feet so as to carry it over Neebing Ave., and the proposed branch line; and construct temporary structure across said Neebing Ave.; and rescinding Orders Nos. [illegible] and [illegible], dated [illegible] August [illegible], and October 11th, 1912.

17870—October [illegible]—Directing the Cumberland Ry. and Coal Co. to equip its cars with automatic couplers and air brakes, within twelve months from date of this Order.

17871—October 30—Approving revised location C.P.R. Sudbury to Sault Ste. Marie Branch as now constructed, from mileage [illegible] from Webbwood, to mileage 34.76 on the Algoma Section, said revision [illegible] Serpent River Indian Reserve.

17872—October 30—Authorizing C.L.O. & W. (C.P.R.) to construct across Three (3) highways, mileage 93.59 to mileage 95.8 in Co. Northumberland, Ontario.

17873—October 30—Authorizing C.L.O. & W. (C.P.R.) to construct across Sidney Street in town of Trenton, mileage 87.14 from Glen Tay, and across West St., mileage 87.41, said town.

17874—October 30—Refusing application of J. A. C. Ethier, M.P., of Ste. Scholastique, Que., for an Order compelling C.P.R. to erect platform for milk shipping purposes between St. Herman and Ste. Scholastique, at point known as Cote St. Lumis, Que.

17875—October 29—Authorizing C.P.R. to open for traffic Moose Jaw North-West Branch from Outlook to Conquest, 9.3 miles, including bridge across South Saskatchewan River.

17876—October 30—Authorizing C.P.R. to construct spur leading to its ballast pit near Olds, Alta., across Edmonton Trail on N.W. ¼ Sec. 19, and across public road allowance between Secs. 19 and 30, Tp. 32, R. 1, W. 5 M., and road allowance between S.W. ¼ Sec. 30, Tp. 32, R. 1, W. [illegible] Tp. [illegible] R. [illegible] W. [illegible]

17877—October 29—Approving proposed location C.P.R. station near the boundary line between Tps. of Amaranth and Melancthon, Co. Dufferin at Shelburne, Ont.

17878—October 30—Authorizing C.P.R. to construct double track across G.T.R. at Delson Jct., and rescinding Order No. 17437, dated September [illegible]

17879—October 30—Allowing correction of plan showing location of sta- [illegible] R[illegible], C.P.R., Boissevain to Lauder Branch.

17880—October 29—Authorizing C.P.R. to construct spur for the Ontario Wind Engine and Pump Co., Calgary, Alberta.

17881—October 29—Authorizing C.P.R. to construct proposed bridge No. 8.7 on the Interprovincial and James Bay Ry., in Province of Quebec.

17882—October 29—Authorizing C.P.R. to open for traffic double track of Moose Jaw Subdivision, from Belle Plaine, mileage 117.0, to Pasqua, [illegible]

17883—October 30—Further extending, until November 30th, 1913, the time within which C.P.R. complete branch line across certain highways [illegible] Marquette.

17884—October 29—Authorizing Esquimalt & Nanaimo Ry. to construct bridge No. 8.5 ever Little Qualicum River, on its Comox Extension, B.C.

17885—October 29—Authorizing C.N.O.R. to construct across Three (3) highways on its Hawkesbury-Monrteal Line, Parish of St. Laurent, Co. Jacques-Cartier, Quebec.

17886—October 30—Rescinding Order No. 17782, dated October 17th, [illegible]

17887—October 31—Authorizing C.N.O.R. to construct across and divert public road between Lots 10 and 11, Con. 8, Tp. Chisholm, District of Nipissing, Ont.

17888—October 30—Authorizing C.N.O.R. to construct across tracks of the Montreal Tramways Co. near Cartierville, by means of an overhead structure.

17889—October 29—Authorizing C.N.R. to construct its Swift Current Extension across Two (2) highways, in Prov. Sask.

17890—October 29—Authorizing C.L.O. & W. (C.P.R.) to construct [illegible] Province of Ontario.

17891—October 30—Authorizing C.L.O. & W. (C.P.R.) to construct across Nine (9) highways, Tp. Tyendinega, mileage 59.45 to mileage 65.75, Ontario.

17892—October 30—Approving location G.T.P. Branch Lines Co. Moose Jaw Northwest Branch from East Line of Sec. 10, Tp. 21, R. 4, to East [illegible] Tp. [illegible] R. [illegible] W. [illegible] M. [illegible]

17893—October 30—Authorizing G.T.R. to construct bridge No. 41, mileage 109.35, 20th District, Middle Division, over creek and public road [illegible]

17894—October 29—Authorizing the Corporation of city of Saskatoon, Sask., to carry its Municipal Street Rly. across C.P.R. at Avenue A and at Twenty-third St., Saskatoon.

17895—October 31—Dismissing complaint of Canada Cement Co., Ltd., [illegible]

[illegible] road at mileage 88.2, Calgary-Boundary Branch, in N.E. ¼ Sec. 9, Tp [illegible]

[illegible] C.P.R. to construct [illegible] D. L. [illegible] on Lots Cadastral No. 328, in incorporated village of St. Louis Parish Montreal, Que., now in city of Montreal, at Mile End Station, Que.

17898—October 31—Authorizing C.P.R. to construct spur into the premises of the Department of Natural Resources for the C.P.R., on west [illegible] Sec. 14, Tp. [illegible], R. [illegible], W. [illegible] M., at Strathmore, Alberta.

17899—October 30—Authorizing C.P.R. to construct an industrial spur for Sampson Walker, Winnipeg, Manitoba.

17900—October 31—Dismissing application of W. Harris Dawson and residents in vicinity of Stonefield, Que., for an Order directing C.P.R. to stop trains at road between Staynerville and Grenville Stations, to pick shipments of cream.

17901—October 30—Approving C.P.R. Plan No. 50177, dated October 24th, 1912, showing extension of bridge No. 0.41, Fort William Terminals, Ontario.

17902—October 31—Approving proposed layout of C.N.O.R. station grounds at Clarendon, Twp. Clarendon, Co. Pontiac, Que.

17903—October 29—Authorizing the city of Saskatoon, Sask., to carry its Municipal Street Railway across C.P.R., at Twentieth Street, said city.

17904—October [illegible]—Authorizing C.P.R. to [illegible] station building at l'Acadie, Parish Ste. Marguerite de Blairfindie, mileage 24.51, Farnham Section.

17905—October 31—Approving location F.T.P. Ry. proposed station at South Hazelton, on Lot 9, Cassiar District, B.C.

17906—November 2—Approving location C.N.O.R. through North Bay, Ontario, mileage 343.55 to mileage 346.42 from Montreal, (North Bay to Capreol Jct., Line).

17907—October 26—Authorizing G.T.P. Ry. to construct spur for Thomas Jackson & Son, city of Winnipeg, Manitoba.

17908—October 2—Authorizing C.N.R. to construct proposed cut-off through city of Winnipeg, to connect its Fort Rouge Yards with its Eastern Yards.

General Order No. 95—November 2—Directing that whenever a railway company subject to the jurisdiction of the Board, issues an embargo against any traffic, it shall, within 48 hours thereafter file with the Board copy of such embargo, with statement of conditions rendering such embargo necessary, the action required to remove such conditions, and probable time such embargo will be continued. And when such embargo is withdrawn or cancelled, the company shall forthwith file with the Board copy of such withdrawal or cancellation.

17909—November 4—Certifying that correction of error, in location plan of Toronto Eastern Ry. Co., in Lot 13, Con. 2, Tp. of Darlington, at town of Bowmanville, is allowed, upon condition that the company cross mill pond by trestle work and do no filling in the mill pond.

17910—November 4—Authorizing C.L.O. & W. (C.P.R.) to construct bridge No. 11.15, in Province of Ontario.

17911—November 6—Postponing, to and including the 31st day of December, 1912, the effective dates of the following tariffs covering increased charges for cartage: G.T.R., C.R.C. No. E. 2627; C.P.R., C.R.C. No. E. 2467; C.N.R., C.R.C. No. E. 184; P.M.R.R., C.R.C. No. 1533; M.C.R.R., C.R.C. No. 1967; C.W. & L.E., C.R.C. No. 254; Q.M. & S., C.R.C. No. 459; K. & P. Ry., C.R.C. No. 421; N.Y.C. & H.R.R., C.R.C. No. 2414; T.H. & B., C.R.C. No. [illegible] N.Y. [illegible] C.R.C. No. [illegible]

17912—November [illegible] N. St. C. & T. Ry. to [illegible] to property of Thorold Pulp Co., Ltd., town of Thorold, Co. Welland, and to property of Interlake Tissue Mills Co., Ltd., village of Merritton, Co. Lincoln.

17913—November 4—Authorizing St. John & Que. Ry. to cross, by overhead bridge, tracks of C.P.R. at station 2608.69, between 49th and 50th miles, north of McAdam Jct., northern section of Atlantic Division.

17914—November 5—Authorizing C.L.O. & W. (C.P.R.) to construct across Toronto and Eastern Ry., by overhead bridge, at mileage 162.98, town of Whitby, Co. Ontario, Ont.

17915—November 4—Authorizing C.P.R. to construct across public road, Lot No. 59, Parish Kildonan, Man., (main line, Winnipeg to East Selkirk).

17916—October 31—Approving location C.P.R. Swift Current-Southeasterly Branch from a point in Sec. 11, Tp. 11, R. 10, W. 3 M., to Junction with its Moose Jaw-Southwesterly Branch in Sec. 23, Tp. 10, R. 1, W. 3 M., mileage [illegible] to mileage [illegible], and to cross [illegible] highways.

17917—November 5—Directing C.P.R. to remove embargo on sand loaded in cars other than its own, shipped into Winnipeg from points on C.N.R. line.

17918—November 2—Authorizing C.N.R. to construct spur for D. R. Fraser & Co., Ltd., Edmonton, Alta.

17919—November 5—Authorizing C.N.O.R. to construct across Park Avenue, city of Montreal, Quebec.

17920—November 5—Authorizing C.N.O.R. to construct across Mance Street, city of Montreal, Quebec.

17921—October 31—Authorizing C.N.O.R. to construct across McPherson Avenue, city of Montreal, Quebec.

17922—November 4—Directing C.N.Q.R. to provide a flag station for passenger purposes only at Larose Station, Quebec.

17923—November 5—Authorizing G.T.P. Branch Lines Co. to divert Lake View Avenue, Moose Jaw, and to construct Regina-Moose Jaw Branch under such diversion, mileage 41.7, Dist. Moose Jaw, Saskatchewan.

17924—November 4—Authorizing G.T.R. to construct siding, and spur therefrom, and to reconstruct or deviate siding to the Breithaupt Leather Co., Ltd., said line commencing at a point on its railway on Fox St., north of Cambridge St., Penetanguishene, Ont., thence extending northerly upon and along Fox St., to the Dominion Stove and Foundry Co., Ltd.

17925—November 4—Authorizing G.T.R. to construct siding for the Sarnia Chain Co., Sarnia, Ontario.

17926—November 2—Authorizing G.T.R. to construct an additional track and reconstruct existing track across road allowance between 5th and 6th Concessions, Tp. Thorah, Ont., and to construct siding commencing east of Beaverton Station on Lot 12, Con. 5, Tp. Thorah, extending to premises of Snelgrove and Teer, (Beaverton Brick & Tile Co.), on Lot 12, Con. 5.

17927—November 4—Authorinzing G.T.R. to construct the northerly track across Cote Noir Road, Parish St. Antoine De Longueuil, Quebec.

17928—November 2—Directing G.T.R. to install two sets of gates at crossing of Lapiniere Road, between towns of Greenfield Park and St. Lambert, Que.

The Canadian Engineer

An Engineering Weekly

LAYING A DEEP SEWER IN BAD GROUND.

By GEO. PHELPS, C. E.*

On one section of the sewerage scheme which has recently been carried out in North Toronto, and which was designed by T. Aird Murray, consulting engineer, Toronto, Ont., a part of the main trunk sewer is laid at a depth of about 30 feet. The following account of the work shows some of the difficulties which were encountered and the methods adopted in overcoming the same.

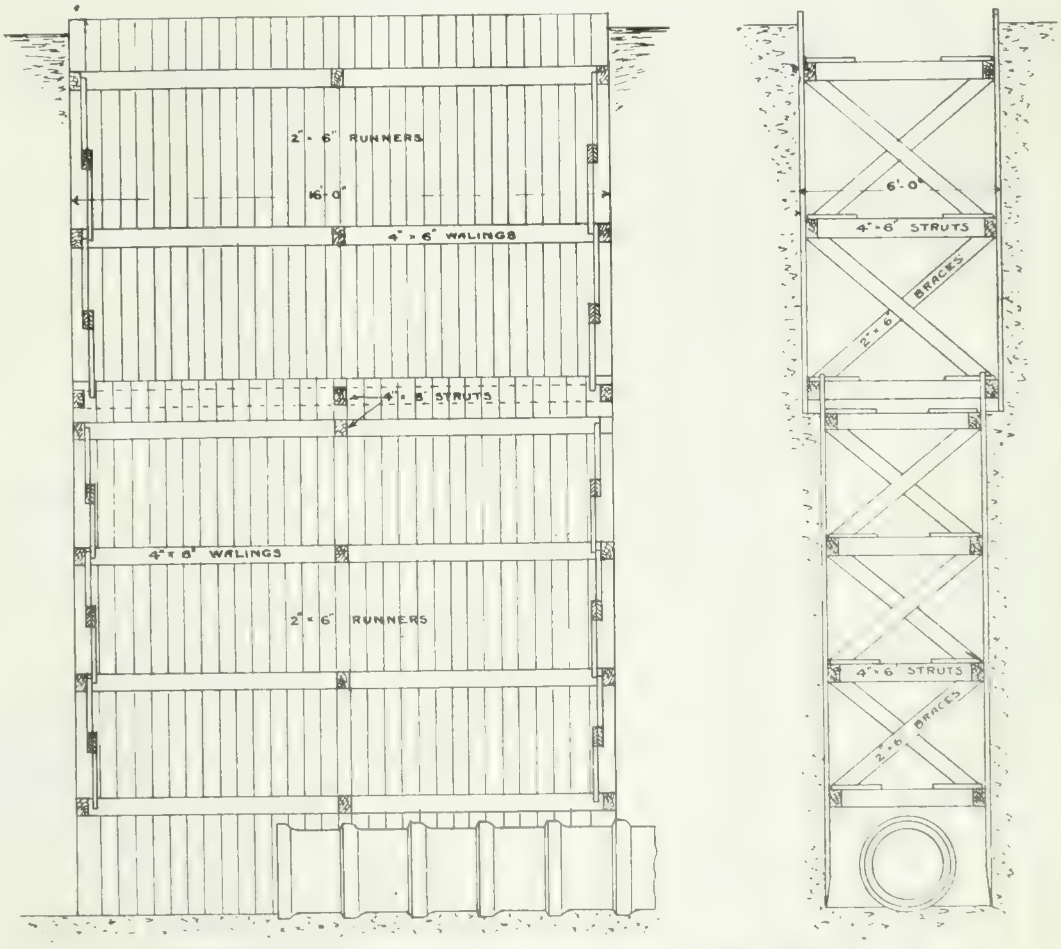

Fig. 1.—Plan Showing Cross Sectional Views of a Top and Bottom Setting of Timber.

The sewer has a total length of nearly two miles; about 2,200 feet of this consists of 20-inch diameter pipes, and 7,000 feet of 24-inch, laid at a grade of 1 in 700. It passes through ground of varying character and at depths for the most part between 20 and 30 feet. Some of the deep work presented no special difficulty beyond hard picking and digging, but towards the lower end of the sewer, water and running sand interfered considerably with the progress of the work. The 20-inch pipes were laid during the summer weather, the greatest depth being about 24 feet, and the soil for practically the whole length of this part consisted of very hard clays and shale. Most of the trenching was done by short open cuts and tunnels about 20 feet long. The sides were so firm that no timbering beyond the stages for shovelling were required, and no water was encountered.

The sewer crosses a creek near where the 20-inch and 24-inch pipes join, and a little further on the ground quickly changes from the hard clay and shale to sand. The following section was laid during the fall of 1911; the greatest depth is about 24 feet, and although the greater part of the work was in sand, no timbering of any importance was required and the trench was free from water. A large part of this section also was carried out on the open cut and tunnel principle.

At the time these two sections were laid there was no outlet for the water at the lower end of the sewer, but pumping was not found necessary, as the trench was dry throughout the whole of the length.

The remainder of the 24-inch sewer, about three-quarters of a mile in length, passed through some bad ground and proved a difficult and costly piece of work. In November, 1911, although the main outfall sewer to which this section joins, was not completed, it was decided to proceed with this part of the work or, it was feared, a large part of the sewer system would be held up for want of an outlet. It having been ascertained by sinking trial holes that there would be water to contend with, a pit was sunk at the point of junction with the outfall sewer. A steam boiler and pulsometer were provided for dealing with the water, which was met with at a depth of about 16 feet. The sewer here is 30 feet deep, the trench being in sand the whole depth. From this point to the next manhole there is a fairly steep grade, sufficient to carry the water and fine sand which came with it through the sewer as it was laid to the pump sump.

---

* Engineer in charge of North Toronto sewerage system.

It may here be said that the pulsometer did not give entire satisfaction for the work. In capacity it was found to be more than sufficient to deal with the water from the trench, and it only required to be worked intermittently. For this reason the sand which was carried by the water settled down on the valves during the periods of rest, and there was often a delay in getting the pump to start again.

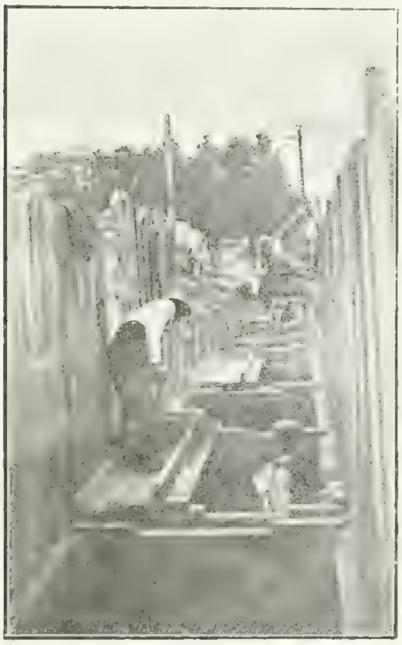

Fig. 2.—View of Trench, Showing Timbering in Position.

After passing the first manhole to the south of this point, the line of the sewer lay between a row of telephone poles and the fences of the property alongside the road, giving a width to work in of only 8 to 10 feet, which was obviously insufficient to accommodate the excavated material in addition to the trench. The use of a conveyer for hoisting and backfilling the earth was considered, but this idea was given up as being impracticable, chiefly owing to the interference of the telephone poles. The open cut and tunnel principle could not be adopted here on account of the quicksand and water, the only reasonable method apparently being the one adopted, viz., of open cutting the whole way by manual labor and removing the material from the trench by stages. The grade from this point on is 1 in 700.

The trench had necessarily to be timbered in a very substantial manner, as the sand was loose and the sides of the trench quickly fell in if unsupported. In fact, the conditions soon got so bad that it was found necessary to timber the trench with close sheeting from top to bottom. The work was carried on through the winter in order that the trunk sewer might be completed in good time, and the severe weather helped to make progress slow. Not only was there three feet of frost to break through at the top, but the excavated material froze almost solid, making the filling-in quite a large part of the work. Frost wedges and dynamite were used to break up the material for filling in the trench.

Although it was found possible to continue the laying of this sewer right through the severe weather of last winter, except for a few odd days, there is little doubt that from an economical point of view the laying of a deep sewer in ground where quicksand and water are met with had better be stopped in the winter, unless, as here, it is a case of being pressed for time. If such work must be carried on in severe frost, some kind of conveyer should, if possible, be used for backfilling the excavated material over the pipes laid as soon as it is removed from the trench, not allowing it time to freeze at the top of the ground.

Shortly after the commencement of the work on the flat grade it was found impossible to keep the sewer free from the sand which was carried in suspension in the water, and which, being very fine, quickly settled down in the pipes and formed an obstruction. Attempts were made by means of rods and chains drawn through to keep the pipes clear, also by flushing from a hydrant. But the level of the water could not be kept down sufficiently to make good joints, and pumping in front of the pipe-layers had to be resorted to. A four horse-power vertical gasoline engine and a belt-driven centrifugal pump were provided for this purpose, the pump being set down in the trench about 10 feet above the invert of the sewer; 35 feet of flexible suction hose was attached to the pump, making it possible to lay about 70 feet of pipe before moving the pump further along the trench. The gasoline engine occasionally gave a little trouble, but the centrifugal pump proved quite satisfactory for dealing with the very sandy water, which was raised to the surface and discharged on the other side of the road.

The pipe joints were made in the usual way with cement mortar, gaskets being first put into the sockets of the pipe. Only a few pipes, about eight or ten, were laid at a stretch, the method of procedure being to excavate a length of trench, except a foot or so at the bottom, sufficient for the length of pipes to be laid; that part of the trench was then cleared of the stages, and the last level of the bottom got out while the pipes were being laid. This was necessary on account of the rapidity with which the trench silted up. The joints were cemented and covered over with sods, and the sand which was being removed from the bottom of the trench filled on to the top of the pipes shortly after. The water was not allowed to rise in the trench again or flow into the pipes until after the cement had set. Derricks were used for lowering the pipes into the trench, as well as for drawing the timbers after the pipes were laid. Two men on the derrick were able to handle the pipes with ease, and the pipes were by this means lowered and set in position in the shortest possible time. These derricks were rigged up on the job, a double purchase winch being used, fixed to a wooden frame - work with wooden mast and boom.

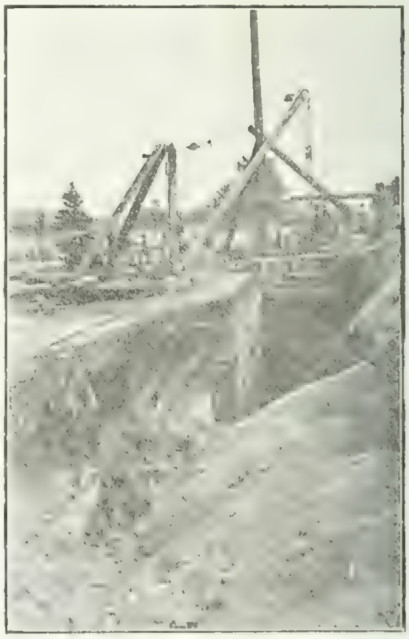

Fig. 3.—View of Trench After Removal of Timbering.

It is generally recognized to be a matter of some difficulty to make good cement joints in a wet trench, but that this can be done providing great care is taken in the jointing, and the water kept well pumped out in front of the pipe laying, is demonstrated in the present case.

Before leaving at the end of the day a stopper was put in the last pipe laid, to prevent the sand washing into the pipes at night. The sand flowed so freely into the trench that often, after standing over the week-end, it had filled the trench up to the level of the top of the pipes. The bottom of the trench was, as a rule, good, the quicksand coming from a few feet higher up. In some places, however, where the bottom was soft, timbers were put in to give a firm bearing for the pipes. As a result of the flow of sand into the trench, caves were formed behind the sheeting, and when for any reason a delay occurred causing the trench to be left open a little longer than usual, big falls of sand took place, due to the cave and the weight of earth above. These often pulled down the top setting of timber a few feet with it and causing the walings to snap. This constituted a great danger and the work was delayed on several occasions by the caving in of the sides of the trench from this cause. The system of cross braces shown in Fig. 1 was adopted to prevent the occurrence. Extra diagonal braces were often put in as well, but even this did not always prevent the settling down of the timber work with the falling sides. The timber consisted of two settings of 2-in. x 6-in. pine runners, the top setting being 12 feet deep and the bottom 16 feet deep. The walings and struts were of 4-in x 6-in. pine, and the cross braces of 2-in. x 6-in. pine. A uniform width of trench was kept, and each setting was 16 feet in length, this being the length of walings used. The walings were about four feet apart vertically, three on each side for a top setting, and four for a bottom setting. The cross braces and 4-in. x 6-in. struts were placed at each end of the walings, in addition to 4-in. x 6-in. struts in the middle, the timbering thus being divided up into 8-foot bays. After the bottom setting of timber had been driven down to the full depth, the joints of the runners were covered with short lengths of 1-in. boards to keep back the sand as much as possible. This helped considerably, but did not entirely prevent the sand from washing in.

The drawing of the timbers after the pipes had been laid was attended with some danger. The bottom setting was first drawn, often exposing big caves in the sides of the trench where the material had washed away. These, with the trench, were filled up to the bottom of the next setting before any of the top timbers were disturbed. On removing the struts from the top setting the sides of the trench often fell in from several feet back to the great danger of the timbermen, but fortunately the work was completed without any serious mishap from this cause.

In passing the telephone poles, which came immediately on the side of the trench, the top setting of timber was left in for safety. In addition, stays were placed on the poles and left there after completion of the work to protect them from heeling over or sinking until the trench settled down quite firm. In some places, where the ground was very bad, particularly at a point where the trench passed close to a grove of trees, the whole of the timbering was left in the trench, and after filling such places a large amount of surplus earth remained to be hauled away. The trenches have shown very little sign of settling down since being filled and it is likely that the caves left behind the timbering where it was not drawn will silt up from underneath quicker than the filling material will find its way through from above.

After completion of the sewer it was found necessary to do a certain amount of flushing to remove the sand from the pipes. The sewer is now in satisfactory operation.

It is interesting to note that during the excavation of the trenches, which were situated some six miles from Lake Ontario and at a level of about 250 feet above the lake, a number of boulders were continually being met with, some of them over a ton in weight. The rocks from which these came were of a very varied character, and many of the boulders showed by their scored surfaces unmistakable signs of having been ice borne. No doubt many of them had been brought from long distances and deposited here when the lakes covered a larger area than they do at the present time.

In the fall of 1911 this work was taken out of the contractor's hands and conducted by myself under the direction of E. A. James, the engineer for North Toronto, Ont.

ROADS OF SASKATCHEWAN.*

By A. J. McPherson.†

I have to express my gratification at being allowed the opportunity of laying before you some information regarding Saskatchewan roads and also at being able to attend your convention, as I am very much interested in learning the objects and aims of your association. I can say for the Highway Commission of Saskatchewan that they will do what they can to further the aims of the association, and from what information I have had up to the present is should be done without any confliction with our present policy, as we appear to be trying to arrange our provincial affairs entirely in accord with the ideas expressed by those of your officers whom I have had the pleasure of meeting. I understand that one of the objects of your association is to bring into existence a national highway leading from coast to coast across the Dominion. I propose to show you before I am through how this can be accomplished as regards that part of it lying within Saskatchewan. I will also try and outline the general policy regarding roads which we have been following for the last five or six years with more or less success.

Importance and Benefits of Good Roads.—It hardly seems necessary to refer to the importance or the benefits to be derived from good roads before such a convention as this, the members of which are all more or less enthusiastic, their presence here showing that they realize the importance of the question. The importance of proper means for facilitating easy transportation, however, cannot be over estimated. Man is naturally gregarious in his nature and everywhere he is found living in tribes and flocks. He attains his greatest success and most advanced development when living in communities. If a man lived in isolation and depended entirely on his own efforts for everything he needed he would be compelled to live in a very crude way and any advancement he made during his lifetime would die with him. This is an age of specialization and we find one community will confine its efforts to the production of one article of commerce and another to another. Other communities are engaged solely in the manufacture of one class of machinery while still others will devote all their time to the development of ideas, education, etc. It is necessary that articles thus produced or manufactured be interchanged and transported to where they are needed, and we find a commerce resulting in articles grown or manufactured in all parts of the world. The whole fabric of our modern civilization depends on the interchange of ideas and the gradual improvement on them by succeeding generations. It is thus that advancement is made. Means of communication are essential that this commerce of ideas and commodities be carried on, and the railways and highways with the navigation of the waters form these means of communication. The first trail between the haunts of two savage tribes was the beginning of civilization. We thus see that our modern civilization has a close dependence on the state of the highways. I once heard it said that three of the most important questions affecting mankind were religion, education and transportation, and as one could neither go to church nor to school without roads leading to these places when we undertook to improve the roads we were really engaged in the most pious work.

---

* Read at convention of Canadian Highway Association, held in Winnipeg.

† Chairman of the Board of Highway Commissioners of Saskatchewan.

A farm adjoining a good road will sell for a higher price and is worth more than one on a poor road. There is a great advantage in having a farm within reasonable distance of a railway station. So much so is this the case that the matter of the distance from the railway has a very material effect on the price of land. Anything grown on a farm has little value unless it can be transported to a market, and many homesteaders look to the improvement of means of communication to give a value to their homesteads which they have not now. Anything that will facilitate the ready access to market from the farms cannot help but add to the value of them, and good roads are as essential a part of the machinery for doing successful business in the country as suitable houses, stables and other improvements which farmers recognize as being absolutely necessary.

So much money is wasted in transportation over bad roads that it is cheaper to improve the roads than to leave them as they are, and money invested in roads will give a return of the greatest dividends.

In many sections at certain times of the year the condition of the roads prohibits people from getting about and people lose their interest in current events, become dissatisfied and are not in a position to carry on their business with the enthusiasm which is so necessary to make a success of it. Bad roads react in this way so as to affect all the departments of life and improving the roads indirectly raises the standard of living all along the line.

History and Development.—For many years such traffic as existed in Saskatchewan followed along the historic Hudson Bay trails, which had been used by the supply trains of the Hudson Bay Company voyageurs for more than two hundred years. These trails led across country in various directions following the highest and most suitable land, and skirting the rivers between the various forts of the company. When arrangements were made between the Hudson Bay Company and the Dominion of Canada, whereby the latter took over the lands of the West, one of the provisions of the agreement was that the company were to be allowed to carry on their trading operations at their various forts. Later the Dominion passed laws whereby any public travelled road or trail which existed prior to the subdivision of the land could thereafter be reserved for highway purposes and surveys made of the same. In a few cases surveys have been made and rights-of-way have been retained, thus fixing them for permanent roads.

On the advent of the Canadian Pacific Railway in the early eighties several trading centres and towns developed, such as Moose Jaw, Qu'Appelle, Regina, Moosomin, Swift Current, Maple Creek, etc., and for a number of years trails led out from these places in every direction, in many cases replacing the old Hudson Bay trails.

About 1890 there commenced an immigration which has gradually grown larger until in the last few years it has become a regular flood, and has had the effect of covering nearly the whole of the southern part of Saskatchewan with settlers. This has been attended with considerable railway development with the resulting coming into existence of new towns and market places. As the settlers commenced to break up the land many of these old trails have been ploughed up, as in most cases they run across country in the most direct and suitable lines, no attempt having been made to follow surveyed allowances provided for roads. In the rougher parts of the country, which are sparsely settled, many of them are still in existence and are being used, but the traffic is adjusting itself to new conditions brought about by settlement and railway development, and follows the most suitable road allowances.

When a railroad is constructed through a new section of country a new string of towns or shipping points is created. It is found that traffic immediately abandons all its old lines and around each shipping point a new system of roads develops and is immediately necessary. The lines along which traffic will develop are the most direct lines that are suitable leading to these new towns, and immediately a lot of improvements are necessary to facilitate traffic over these new lines. I have heard it boasted that the Canadian Northern Railway have averaged more than a mile of railway brought into operation per day for the last seven or eight years. As this means a new town or shipping point about each week, and as the other railroads are carrying on a similar development, and as each new town or shipping point necessitates the improvement of a system of roads leading to it fit for the traffic, one gets some idea of the problem the various authorities having in hand the improvement of the roads have to cope with.

Traffic on these new systems may be divided into two classes, that between the towns which is ordinarily light traffic, and that from the country to the town. The first usually follows approximately parallel to the railway, while the more important lines followed by the latter are the most direct lines from each town out into the country, and as nearly as possible at right angles to the railway. In some cases both kinds of traffic follow the same lines as from a town on one railway to a town on another railway, and in these cases a very heavy traffic may develop and an important road come into existence. In many of the more advanced and wealthy parts of the country a new phase of traffic is developing. Many of the farmers and townspeople now use automobiles, and the traffic from town to town by this means is increasing and rendering these roads more important. There is thus a traffic developed that is not so local in character as the ordinary traffic of the country and the lines which it seeks to take are more of the nature of through lines between the larger towns, cities, summer resorts and other such objective points.

Organization.—The authorities provided for undertaking road improvement work in the province of Saskatchewan are the provincial government and the local authorities, such as councils of cities, towns, villages, rural municipalities and local improvement districts. There is no well defined limit to the jurisdiction of these various authorities. In practice the local councils, which collect taxes for the purpose, direct their expenditure of these taxes within the limits of their municipalities. The provincial government build nearly all the bridges required and attempts to confine its expenditure to construction of main roads, and the construction or reconstruction of important works that are beyond the means of the local authorities. The maintenance of all the roads devolves on the local authorities.

There is no recognization of a statute labor system in the province, but in many municipalities the farmers are employed by the councillors to work on the roads for a few days in the year and the payments made for this work are returned in lieu of paying taxes. This is practically equivalent to a statute labor system. In the newer parts of the province, where the settlers are just commencing, if the local authorities are going to do anything on the roads, this is about the only feasible plan, as these settlers are not in a position to pay their taxes in cash. In many of the older districts the farmers cannot be got to work on the roads, being so busy on their farms, and many of the muicipalities have gangs organized to commence in the spring and work on the roads through the full season, thus making a business of constructing roads to the exclusion of other interests, and securing much better work and more value for the money expended. Some of the rural municipalities have issued debentures and have spent considerable sums from capital account in constructing roads.

The provincial government does road improvement work by two methods: first, by gangs directly under the supervision of the government officials, and by assisting the municipalities.

In determining the location of the roads where improvements paid for by the province are warranted, the provincial authorities recognize that roads should be classified as to their importance. The destination of most of the traffic over the roads is some point on a railway or a market town thereon. The traffic collects from the outlying districts where traffic exists or where it is purely local, and forces itself along certain well defined lines until, as it nears the town, there are certain lines along which it becomes very heavy. The nearer the town one gets the heavier it becomes. These certain lines then develop into main roads for traffic. The local authorities are called upon to maintain a road with a very heavy traffic, much of which is derived from a part of the country outside their jurisdiction. It is quite as beneficial, necessary and important to the people of these outlying districts that the part of the road nearest the town and furthest away from themselves be in as good shape as that nearest their own front doors. It is more expensive to construct and maintain a leading road carrying a heavy traffic such as this than one that simply carries the local traffic of the immediate district, as the road has to be wider and it wears out sooner. Is it, therefore, entirely fair to ask these local authorities to stand this extra expense for the benefit partially of outlying peoples who bear no share of it? I do not think it is, and as an evidence that many of these authorities insensibly object to it, we find that often the nearer one comes to a town the worse the road becomes, until the last mile into the town is the worst of all. As the improvement of roads such as this will benefit a large number of residents scattered over an area that is larger than the usual local district it would seem to be a field where provincial funds could be employed to advantage and with fairness to all concerned, and accordingly the provincial authorities have been pursuing a policy of confining as much as possible the expenditure of provincial funds to the improvement of main roads.

In a new country such as Saskatchewan, where development has taken place so rapidly, many improvements are urgently required which are so large and expensive as to be beyond the means of the local authorities, even when located on purely local roads. Nearly all bridges of any size, long grades across marshes and sloughs, side hill roads across ravines, etc., come in this class and the provincial authorities could not but recognize that if these much needed works were to receive attention it must be from provincial funds. As a result, practically all bridges of 20-ft. span and over, and many culverts and small bridges have been constructed by the provincial government and in most cases the maintenance has also devolved on the provincial authorities.

Systems for the administration of the provincial funds available for road improvement have been tried and a system gradually evolved which seems to meet the conditions as they exist throughout the country.

In 1906, the year after the province was formed, the method that was theretofore in force was followed. When it was decided to carry out an improvement in some certain locality one of the local residents who was known to have ability in that kind of work was appointed to organize the local labor and do it. The result of this system was that the improvement of roads was always considered a secondary matter and the work was attended to or not, depending on whether the appointee found time to undertake it after attending to his own business, and as a result, in many cases, the work was not done or the money was spent at a season of the year when the most value could not be obtained for the amount expended.

In 1907 the system of administering the vote was changed with the idea of overcoming the defects observable during 1906. Instead of local men being appointed, the best men that could be selected from the list of foremen employed in 1906 were appointed as road foremen to act during the full season and to go around from place to place where it was decided to make improvements, organize the local labor, and see that the work was properly done. A great improvement was noticed under this system as the season advanced. These foremen rapidly became expert at laying out the work and directing how it should be done, wasted less in misdirected efforts, and the quality and style of the work throughout the province became more uniform.

The same policy, with slight modifications to meet changing conditions in different years and in different parts of the country, was followed in 1908 and 1909, and regarding a large part of the expenditure on roads up to the present time. Conferences of these foremen have been held, many manuals and publications regarding road matters have been distributed to them and to the local authorities, and a force of skilful inspectors has been constantly kept visiting them during the progress of their work, the result being that we have now a large number of men scattered over the province in all parts who have an excellent idea of road building and of what is necessary in this regard to meet varying local conditions.

In 1910 this policy of education was extended more directly than heretofore to the local authorities by asking them to work out their own problems and sending what assistance was possible to them in doing so. This was effected by making grants, under regulations approved by the Lieutenant-Governor-in-Council to all municipalities who had completed their organization under the rural municipality act whereby the work had to conform to a certain standard, and they had to collect certain information, thus ensuring a certain amount of study of conditions in the municipality before they would be entitled to the grant. This system has produced a good effect and has given satisfaction where properly worked out.

A large number of bridges, deemed advisable to construct as steel bridges on concrete foundations or of reinforced concrete, have been treated as permanent structures and paid for out of capital, but all the road work and the majority of the bridge work has up to the present been met from the current revenue of the province. Many of these improvements are an undoubted permanent asset to the province, and should be considered as capital and treated accordingly, while a great deal of the work, such as grading, minor improvements in filling holes, maintenance of bridges, etc., the result of which will disappear in a few years, should properly be met from the current revenue.

It is considered that there is a necessity of a more rapid development regarding works which are of a more purely capital nature, and with this object in view provision was made by legislation in 1912 for meeting the cost of these improvements to the extent of $5,000,000, and it is the intention to proceed as fast as is considered advisable, consistent with economy, efficiency and the resources available in the way of labor and equipment, with the prosecution of the work. This is additional to the ordinary expenditures undertaken as in the past, but the latter will be made to cover works of a more purely maintenance character with the tendency constantly existent to spend the money in such a way as to produce permanent results.

A commission was provided for by legislation to administer the funds available for road improvement from various provincial sources, and this commission has had the matter in hand during 1912. The commission have followed the same methods in the distribution of the funds, i.e., in enlisting the interest and co-operation of the local authorities in various ways and in the recognition of principles as already outlined regarding works of a provincial nature, such as main roads, large and expensive works beyond the means of the local authorities, etc. They have, however, extended the idea somewhat, consistent with the larger amount of money available, and have endeavored to select roads in each municipality which, while being main roads, will also form a system of roads joining up properly with systems in surrounding municipalities and giving proper means of access from all parts of the country in the most direct manner possible to the market places and towns and between the towns.

The roads forming these systems thus become through-roads between the towns, as well as serving the local traffic, and by linking up the more important of these main roads a provincial system is developed which warrants the expenditure thereon of a larger proportion of provincial funds. The most important roads of this provincial system lead between the cities and other places where large numbers of the population wish to go, and the section of the national highway within Saskatchewan will be made up of those roads from the provincial system leading in the proper direction and properly located to join up with the parts of such a proposed road in Manitoba and Alberta, and a little concentration on such a through-road where gaps may occur will make it a through-road suitable for traffic. A further concentration of attention will gradually raise the standard from the usual earth road to a good hard gravel or macadamized road in a few years. This will be brought about by the macadamizing or gravelling of the parts of it through the more wealthy and populous districts and where suitable material is readily available at first, and the extending of this out to the parts in more outlying territory.

The local authorities have been asked to take these things into their consideration and have spent a great deal of time and thought in working out proper systems. The commission, under regulations adopted by order-in-council, assists municipalities in the improvement of any part of such a system, when approved, to the extent of 50 per cent. of the amount expended and have a large staff of inspectors constantly engaged in examining these roads as to their importance, advising and helping the local authorities and giving a general supervision to the work being carried on. Nearly all the inspectors have been recruited from the staff of foremen that have had experience under the system for the last four or five years and are well acquainted with the objects and aims of the commission. It is found that they not only have an effect on the work being carried out by the commission, either by their own gangs or through the organization of the municipalities, but indirectly on the work done by the local councils with whom they are constantly conferring. The amounts being spent on the works are constantly increasing from year to year.

Amount of Funds Available. In [illegible] there was spent in the province on road improvements from provincial funds $[illegible] and from local improvement district sources $[illegible], or a total of $1,156,000.00. In 1912 there was available for road improvement from provincial sources:

Chargeable to current account:	
For bridges	$ 140,000.00
For roads	225,000.00
Aid to municipalities	172,000.00
Ferries and inspection	62,000.00
Chargeable to capital account:	
Bridges and ferries	303,000.00
Road improvement	1,300,000.00
	$2,202,000.00
Raised and spent by rural municipalities from taxes and debentures approximately	1,500,000.00
	$3,702,000.00

In addition to this the cities are spending large sums in permanent pavements and the towns and villages in improving the streets within their limits. This looks like a large amount of money to be spent annually on the roads, but when it is remembered that south of Prince Albert, which is almost wholly settled, there are approximately 250,000 miles of road allowances, a large part of which must receive some attention, to enable the settlers access to markets from their farms it is easily seen where it is absorbed.

Class of Roads and Details of Construction.—Up to the present there are very few places in the province where anything more than improvements to make the best possible earth road are undertaken and it is only where gravel is easily available that short stretches of gravelled road have been constructed. In some of the older towns their main streets are gravelled and are kept in very good condition, but so far as the country roads are concerned almost without exception they are simply earth roads.

There are many places throughout the province where the country has developed to a high degree and where, in order to be consistent with conditions, some better form of road than an earth road is warranted.

Settlement in other places has taken place rapidly, with the result that the necessary attention to the roads has not been possible, and many obstructions exist and long stretches of almost, or, at times, impassable, roads prevent ready access to markets. The standard of road to be aimed at must necessarily, therefore, vary for different localities, but it is exceedingly advisable that as high a standard as possible should be set. In some localities gravel and broken stone roads should be constructed, while in others the removal or overcoming of obstructions and the construction of the best earth road possible is immediately advisable with the possibility of a better grade of construction in the near future kept constantly in view.

For many years the highest class of road that will be attainable generally over the country will be the best earth road that can be made. In this age, where every proposal is put to the acid test of the question "Will it pay?" it is proper that it be applied to the construction and improvement of roads. In the more populous cities we find large sums spent in paving the streets with pavements regardless of cost, and their expenditures are no doubt warranted by the results and the amount of the traffic. On the other hand, we find where there is very little traffic that no attempt at improvement beyond making the roads passable is attempted. The amount of money that we are warranted in spending to improve the roads must be in some measure proportionate to the traffic or to the resulting traffic after the improvement is made. It will be found that we do not always cheapen the cost of transportation by spending extravagant sums in improving roads with little traffic and the most expensive road may be one that has been improved beyond the needs of the traffic on it. There is no doubt but what loads can be hauled much cheaper over gravel or macadam roads than over ordinary earth roads, but if we consider the cost of constructing such roads and then apply the interest and a sinking fund that will pay back the cost of the improvement in five or ten years as a charge on the traffic, we will find that the cost of hauling may be by no means lessened. The cost of hauling farm products over our ordinary earth roads, as it is usually done in this country, is from twenty to thirty cents per ton mile. One way of reducing the cost of hauling is to increase the size of the load, use a wagon and a trailer and put four or six horses to draw seven or eight tons in a load. This is the method followed in the mountains, where a great deal of freighting is done hauling supplies to the mines over very indifferent roads. If loads can be hauled both ways, so that there is no unremunerative trip to make, very cheap hauling is done over roads that, in comparison with our ordinary graded prairie roads, would be considered impassable.

I had occasion to have some packing done some years ago in the Yukon district. I found packing on pack horses at that time cost about ⅓ cent per pound per mile, or about $6.00 per ton mile. This was with hay and oats at 8 cents per pound and other prices corresponding. By brushing out the trails and grading the side hills so as to make a road passable for a wagon at a cost of $2,000 to $3,000 per mile, this haulage cost was reduced to $1.00 per ton mile. The interest on the cost of improving in this way and a sinking fund that will pay back the cost in seven or eight years, which is considered about the life of a placer mining camp, comes to about $400 per mile per year. The reduction in the rate for freighting, according to the above figures, is $5.00 per ton mile. If 80 tons per year were hauled over this road the reduction in cost would therefore pay for the improvement, and when, owing to the reduction in the cost of supplies for mining, many otherwise unproductive properties became paying propositions, and by this means a traffic of more like 80 tons per day resulted, it is seen how well warranted the expense was.

The same principles may be applied to the matter of improving ordinary prairie roads. Suppose by gravelling a road at a cost of $2,000 per mile the saving in hauling over it would be five cents per ton mile. This would likely be in the shape of the larger load that could be taken over it or the greater speed with which the same load can be hauled. With interest at 5 per cent. and the principal paid back in 5 years this improvement would be warranted if 10,000 tons or 350,000 bushels of wheat came over it each year, without other traffic. If the road materials can be obtained and assembled at less than $2,000 per mile, a less amount of traffic will warrant the improvement. It will be seen from the above that an earth road in its best condition may be the cheapest road for the traffic, no matter how much money is available for road improvement. On the other hand, it is also seen, especially if considerations that cannot be put into figures in this way are taken into account, that many of our leading roads would well warrant the expenditure of large sums in improving them to a higher standard than simply the best earth roads.

Maintenance.—The maintenance of any road, no matter of what material it is constructed, is a definite case of "a stitch in time saves nine." The nearer the roads come to receiving constant attention the better and more economically will they be maintained. As the local authorities are in the better position to give the roads this constant attention, being, as it were, constantly on the ground, it naturally follows that the maintenance of the roads and bridges should devolve on them, and they should recognize this and provide for it. It will, in most cases, cost far more for any provincial employee to get to a place where some maintenance work is required than the actual cost of doing it when he gets there, and the provincial employees should, therefore, be asked to confine their attention to the work of construction and reconstruction alone.

As nearly all of the highways in the province must continue for years to be simply earth roads, and as even at their best they cut up easily at certain seasons of the year, the government have been experimenting to find out the best methods of maintaining earth roads in their best condition. The experiments performed with road drags indicated that an ordinary road can be kept in its best condition after being properly constructed by running one of these drags over it periodically about six to eight times each season, and a large number of them are now coming into use. It is found that the operation of the drag must be changed to suit different qualities of earth going to form the roads in different parts of the country, but use of them on any road will in a short time indicate the most successful way in which to operate them.

Future Developments.—The highway commission of the provincial government are endeavoring to have the local authorities give special attention to their main lines of traffic and develop systems of roads which will enable any person living in the province to have a good road direct into town from a point within a few miles of his place and to go directly from town to town. They give a tangible incentive to the local authorities to do this by assisting them or contracting with them to make improvements on roads that are considered part of such a system at the expense of the commission. They also make improvements on roads that will form such a system with their own road building organization.

By linking up the main roads in these systems in the proper directions a provincial system will be evolved on which every person wishing to go from one point of the province to another will have a ready means of doing it. The commission have this in view and the local authorities are in many cases showing their accord with it.

There is no reason why in some parts of the country the improving of the main roads in these systems to a higher standard cannot be undertaken and especially this provincial system gradually be constructed as gravel or macadam roads where the material is available.

It is the intention of the commission to take such steps as to give an incentive to do this whenever suitable, and to concentrate efforts as much as possible without sacrificing other considerations along this line so as to work out a proper provincial system of high-class roads in a few years. Where proper material is scarce and expensive this may not be possible. With the object of overcoming this, they are having experiments carried out to see if the ordinary gumbo clay, scattered so widely, cannot be treated in some way whereby it will have a greater resistance to traffic during wet weather and will not form into mud so readily. These experiments would indicate that there is some chance of success along these lines and they are having a sample piece of road built at present to try out a process of burning with straw which has been suggested.

Any information that is obtained from these efforts will be distributed, as fast as it is found reliable, to the authorities who are interested or may be able to use it.

The commission proposes to make a special effort regarding the maintenance of roads in their best condition, and feel that much can be done along this line.

The local authorities are becoming much interested in the work and are giving every evidence of taking hold of it with greater intelligence and knowledge each year, and as they form almost the only means by which any improvement along these lines can be carried out it is very encouraging.

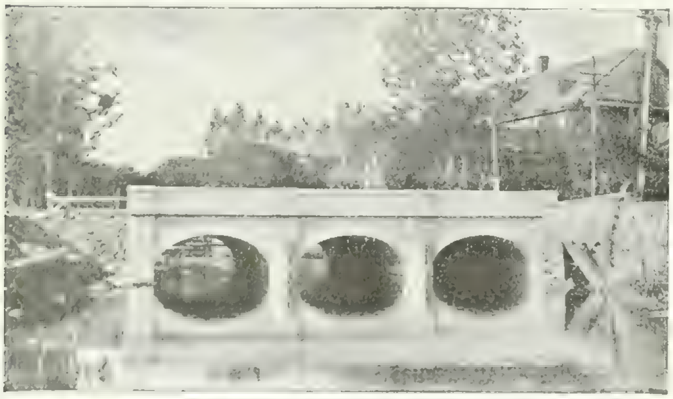
It is hoped by the co-operation of the various authorities in all this work and by keeping up the interest of the general public that the standard condition of the highways in Saskatchewan will be gradually raised, and that eventually the state of the highways will be such that it will be a pleasure at all times to travel over them; that they will entice people to go afield and become acquainted with their fellows, and that they will thus be one of the means of ensuring to Saskatchewan a broad-minded, prosperous and happy people.

◆

AN ATTRACTIVE CONCRETE BRIDGE AT METHUEN, MASS.

The recently completed "New Broadway Bridge," which spans the Spicket River on the road between Lawrence and Methuen, Mass., is an interesting example of what may be accomplished in bridge design with concrete when both utility and aesthetic appearance are of importance. The bridge is a gift to the town of Methuen from Edward F. Searles, its most prominent citizen.

In designing the bridge the Aberthaw Construction Company, of Boston, Mass., who also built it, followed the suggestions of the donor. It was desired to erect a structure that would serve the traffic needs of the town to the best advantage and at the same time add as much as possible to the appearance of that section. Mr. Searles did not desire anything elaborate or ornate, so the bridge was designed with almost severe plainness. It is to its very severity of architectural treatment that much of the attractiveness of the bridge is due.

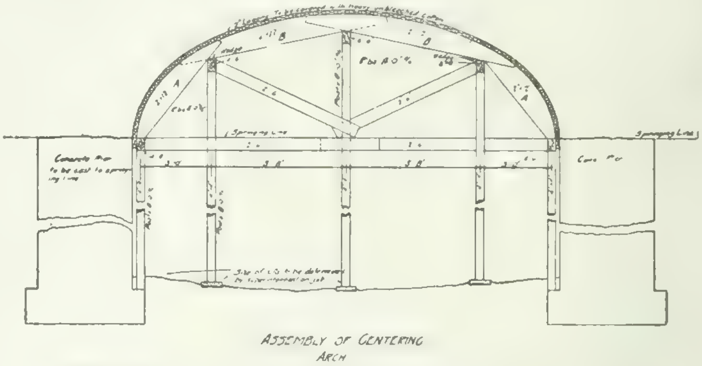


Broadway Bridge at Methuen, Mass.

The bridge is 80 feet long from the end of one abutment to the other, and 74 ft. 2 ins. overall width. It has three arches, each 18 ft. wide, placed on 22-ft. centres. The forms for these arches were detailed at the contractors' office, so that there was no confusion or delay on the job. The details of these forms are shown in the accompanying cut. The concrete footings are 5 feet wide and the piers themselves 4 feet thick. A 1:2:4 mix was used.

Across the central portion of the bridge run the double tracks of the Bay State Street Railway Co. On either side of the car tracks is a roadway, and flanking the roadways are two sidewalks 8 feet wide. The width of the roadway from one sidewalk curb to the other is just 50 ft. The road is of macadam, and between it and the concrete bridge floor is a three-ply waterproofing of felt and asphalt.

As will be seen from the photograph, the parapet on either side of the bridge is without ornamentation, being simply a wall with plain capping. The parapet was chosen in preference to an iron railing, as it added enough to the artistic appearance of the bridge to pay for the extra expense. At either end of the piers is a small buttress of uniform cross section which, despite its plainness, adds considerable to the appearance of the bridge. The surface of the spandrel and parapet walls are picked, while the edges of the arches, the floor, and the parapet capping were rubbed smooth.



Showing Assembly of Centring on Broadway Bridge, Methuen, Mass.

Provision has been made for four electric light posts, one at each buttress. When these are installed, they will add to the general attractiveness of the bridge.

In putting in the piers a small coffer dam of 3-inch matched sheeting was sunk into the gravel bed of the river, and the pier centring was hung from the horizontal sheeting braces.

A 16-inch water main that crossed the river at the bridge was provided for in the following manner: The pipe was carried on a 4-inch I-beam which rested on two trench braces at each pier. The braces placed side by side were expanded until the pipe was brought to the proper level. Then the concrete was poured around the braces and a permanent support at this level was assured.

NEW ENGINEERING LABORATORIES.

The new engineering laboratories at University College, Dundee, are now in use, though they have not been formally opened. The block is two stories in height. On the ground floor there are an hydraulic laboratory, small lecture room, library photographic rooms, and engines and generating plant. On the second floor are accommodated the principal lecture room, the drawing offices. the staff rooms, the workshop, and the stress and cement testing laboratories. Water is supplied to the hydraulic laboratory from a tank at the top of a tower, about 60 ft. above floor level, through an 8-in. main, and is returned to the tank by a motor-driven centrifugal pump which lifts 475 gallons a minute.

The heat engine laboratory is divided into an engine room proper and a boiler and producer house, and the engine plant consists of a horizontal tandem compound engine, with drop and Corliss valves and surface condenser, capable of developing 150 b.h.p. at 100 r.p.m. There are also a Babcock and Wilcox boiler with an auxiliary electric-driven feed pump and economizer, the boiler being fitted with a separately fired superheater, and working up to 250 lb. per square inch; a 30 h.p. gas engine with suction gas producer; a motor-car engine with appliances for quantitative measurements of its power and heat efficiencies, and a 50-ton testing machine.

THE UTILIZATION OF PEAT FUEL.

By H. Poynter Bell.*

The report on the utilization of Peat fuel for the production of power, issued by the Dominion Department of Mines, was mentioned in the columns of *The Canadian Engineer* some weeks ago; it is, however, of such importance that it calls for further mention than could then be given to it. The report is so written as to be useful to power users in general, as well as to engineers, and contains an account of the actions and processes which take place in the producer, and of the construction and manner of operation of the gas engine. A full description is given of the plant and testing apparatus at the fuel testing station at Ottawa, and of changes in the gas-producer and gas-cleaning plants, made during the series of tests in order to obtain better results.

The nature and the results of the tests which were made are simply described for the use of non-technical readers, but, besides this, details of all observations are given in full for the information of engineers and those who have special knowledge of the subject. The very encouraging results which were obtained may be commended particularly to the notice of those whose ideas on the utilization of peat are founded on the failure of some previous attempts in the same direction. Many such attempts were made at a time when the nature and proper methods of using peat were very imperfectly understood in both America and Europe. They were made with unsuitable appliances and often without regard to the differences between Canadian and European peat. Since that time very great improvements have been made in Europe in the methods of treating and using peat, while knowledge about Canadian peat has been considerably advanced, chiefly through the work of the Department of Mines.

The present report shows clearly that with suitable conditions power can be obtained from peat by the use of gas-producers and gas-engines, at a cost which compares favorably with that of power from coal, and may even, in some cases, be at least as low as the cost of hydro-electric power. It is not pretended that this can be the case in all places and for all purposes, but if the power can be raised at or near the peat bog, and more especially if it is required for a fairly uniform load, peat producer gas is clearly a very economical fuel.

It is found that peat in a suitable condition for use in the gas-producer can now be delivered f.o.b. at the bog—that is, at the producer if it is on the spot—for not more than $2 per ton, which is equivalent to $4 or even less per ton for high-grade coal. On this basis electric power can be produced, as shown in the report, at a fuel cost of $8.40 per horse-power per year of 3,000 hours. The whole of the work required on the plant used at Ottawa (60 horse-power) could be done by one man.

The tests were evidently made under fair working conditions, and with the use of only such plant and appliances as are obtainable by everyone. A producer and engine were chosen of a type which had proved successful with European peat. As a result of the experience gained in the earlier tests, changes were made in the producer which, as completely described in the report, may be taken as a type suitable for use with Canadian peat.

The results given, satisfactory as they are, need not be considered to be the best that can possibly be obtained. Apart from improvements which may be made in the getting of the peat, there are various other gas-producers and engines designed for use with peat and it is possible that with some one or more of them even better efficiency may be obtained than that which is shown in the report.

The report gives, further, a description of some heaters intended for utilizing the exhaust heat of gas engines. Tests with these heaters had not been made when the report was written, but particulars are given of tests made elsewhere with heaters of this kind. It appears from these tests that not less than 40 to 50 lbs. (4 to 5 gallons) of water can be heated by the engine jacket and the heater to 190 deg. Fahr. per brake horse-power of the engine, and that the power of the heat so obtained are together equal to from 74 to 80 per cent. of the heat value of the gas supplied to the engine—a very remarkable economy.

In the estimate of cost here given no account has been taken of the savings to be made through the recovery of by-products, and particularly sulphate of ammonia—from the producer-gas. There exists already a demand for sulphate of ammonia in Canada, and its manufacture is very profitable if it is made in large enough quantities, that is to say, if large enough quantities of producer gas are made. The plant originally used for the recovery was rather large and expensive, but it has been found that the process can be greatly simplified and cheapened.

As stated above, the use of peat is economical when the conditions are suitable. One of the most important of these conditions is, of course, the nature of the peat which is to be worked. To start work on a peat bog which has not been properly investigated is mere gambling. The work of investigating Canadian peat bogs is making steady progress under the Department of Mines; a number of good results have been obtained and there can be no doubt that many of the numerous bogs in central and eastern Canada will be found to give peat well suited for making fuel.

NEW WESTMINSTER IMPROVEMENTS.

Definite announcement has now been made that the Great Northern Railway, or rather the Vancouver, Victoria and Esquimalt Railway, will establish their Canadian freight terminals adjoining the eastern boundary of New Westminster within the municipality of Coquitlam. At the last meetings of the New Westminster and Coquitlam councils the railway company asked for the co-operation of these bodies and also that of Burnaby in building a high level bridge over the proposed freight yards. The acreage purchased by them is apparently large, extending into Burnaby municipality.

With this development all the railways operating on the lower mainland of British Columbia have located their yards and freight terminals on the Fraser River. These include the Canadian Pacific Railway at Coquitlam, the Canadian Northern Railway at Port Mann, the British Columbia Electric Railway at South Westminster, and now the Great Northern Railway on the Brunette River, practically in New Westminster.

The mayor and council have recently been taking stock of the large amount of work accomplished on the city streets during this year. The board of works has had $500,000 for grading and macadamizing streets, laying wooden sidewalks and other various improvements, while contracts for $761,000 for paving, cement sidewalks and other permanent improvements have been let. The delay in selling the city bonds, which were finally disposed of at 92½, has prevented all the contracts from being completed this year and held up other work.

The city is starting on the sewer system for Sapperton at the east end. Contracts for the first section of the work, totalling over $200,000, have just been let.

TESTS OF LONG-LEAF PINE BRIDGE TIMBERS.

In line with the past policy of the American Railway Engineering Association to collect and disseminate useful information pertaining to the objects of the association, there has been edited and published recently under the board of direction, a bulletin containing the results of tests of long-leaf pine bridge timbers made by H. B. MacFarland, engineer of tests, for the Atchison, Topeka & Santa Fe Railway System. An abstract of the bulletin is given herewith.

The purpose of these tests was to fully investigate the effect of the full-cell creosote treatment on long-leaf yellow pine bridge timbers. The United States government engineers have demonstrated quite conclusively that the boiling process weakens timber to a very marked degree. Their explanation of this is that the high temperatures used in the steaming tend to break down the cell wall structure and thus weaken the timber.

Inasmuch as there is no steaming process connected with the full-cell treatment used at the Santa Fe treating plants, it has been the opinion of the men in charge of this work that the timber was not materially weakened by the treatment. It was, therefore, decided to make a thorough test of the treated timber and thus determine the facts. It is very important that the strength of treated timber be known, for it is now being used very extensively in bridges, and if the strength is decreased by treatment, proper allowance should be made for this decrease.

Specimens.—The standard stringer for the Santa Fe System is 7 in. x 16 in. x 28 ft. long-leaf yellow pine. This size was, therefore, selected for the tests. Thirty-two such timbers were picked from the stock at the Somerville plant. The stock was at this time quite low and it was, therefore, impossible to get as varied a set of specimens as was desired. None of them contained a large per cent. of sapwood. No attempt was made to pick out the best pieces, though it may be noted that all were in first-class condition. They all had been seasoned for approximately ten months. Each of these sticks was sawed in half, numbered and weighed. One-half of each stick was then creosoted by the full-cell process. The details of the treatment are given below:

Somerville cylinder No. 5.
Run No. 1761, December 2, 1910.
Oil transferred, 11:50 a.m.
Pump started, 12:10 p.m.
Temperature of oil in tank, 200 degrees Fahrenheit.
Temperature in cylinder, 170 degrees Fahrenheit.
Maximum pressure, 150 lbs. per sq. in.
Time of maximum pressure, 1:40 p.m.
Oil dropped to ground tank, 2:25 p.m.
Vacuum started, 2:45 p.m.
Maximum vacuum, inches, 26.
Vacuum broken, 4:15 p.m.
Run closed, 4:30 p.m.
Time consumed in run, 4 hours and 40 minutes.
Process, Full-Cell Creosote.

Specimens Tested in 1911.

NOTE: Odd number is the untreated half of a stringer and the following even number is the treated half.

Each specimen was weighed after treatment, in order to calculate the amount of creosote absorbed per cubic foot.

The 64 pieces were loaded and shipped to the testing laboratory at Topeka immediately after treatment. It was desirable to study the effect of the creosoting on the timbers both immediately after treatment and one year after treatment. Therefore, the 34 untreated specimens and 16 of the treated specimens were tested immediately upon receipt at Topeka and the remaining 16 treated specimens were tested after one year, having been seasoned during the year by laying in an open pile in the yard at Topeka.

Two special specimens were prepared with the others, in order to compare the relative strength of the butt and top portions of the tree. Specimen 13 was the top end and 14 the butt end of one large stick. Both of these were left untreated. Specimen 40 was the top end and 39 the butt end of another large stick. Both of these were treated. All four were tested. It was impossible to determine which was the butt end of the regular specimens, but the two special sticks showed this by position of the sapwood and growth rings.

Methods.—In making the transverse test the stringer was supported on rocking knife edges placed 13 ft. apart on the bed of an Olsen 200,000 lb. testing machine. Six-inch flat plates were placed between the knife edges and the timber to prevent cutting. The load was applied at third points through knife edges and six-inch plates and rollers. An initial load of 500 lbs. was used in order to get a firm bearing on the plates. The deflections were measured by a mirror and adjustable scale and a fine wire, which was fastened at the centre of the beam directly above each knife edge. The load was applied with the machine running at a speed of 0.16 inch per minute.

The specimens tested in compression parallel to the grain were 5 in. x 5 in. x 12 in. A ball and socket plate was placed between the machine bed and the specimen in order that the load might be uniformly applied. Deflections were read by means of a deflectometer. The load was applied at a rate of 0.16 inch per minute.

In making test in compression perpendicular to the grain the specimens were 6 in. x 6 in. x 24 in., and the load was applied through a four-inch plate with slightly rounded corners. The machine speed used was 0.16-inch per minute. A deflectometer was used to measure deflections.

The moisture determinations were, in all cases, made immediately after transverse tests. The samples were obtained by boring nine one-inch holes, one-half inch deep, spaced uniformly, in the end of the specimen. The chips were carefully weighed on a balance and then placed in an oven and kept at a temperature of 200 degrees Fahrenheit for eight hours. The per cent. of moisture was calculated from the loss in weight The percentage is that of dry weight of specimen.

The data regarding number of growth rings per inch were obtained from the large specimens. The rings were counted, starting one inch from the heart and counting for a radius of three inches. The per cent. of sapwood was estimated from measurements of the end area.

The following formulæ were used in the calculations:

Transverse Test.—Load applied at third points.

Load in lbs. per sq. in.:

$$S = \frac{PL}{bd^2} \text{ where,}$$

P = Load in lbs.
L = Length of span in inches
b = Breadth of specimen in inches
d = Depth of specimen in inches
S = Stress in lbs. per sq. in.

Modulus of Rupture:

$$R = \frac{PL}{bd^2} \text{ where,}$$

P = Maximum load in lbs.
R = Modulus of rupture in lbs. per sq. in.
Other symbols as above.

Modulus of Elasticity:

$$E = \frac{PL^3}{4.7bd^3D} \text{ where,}$$

E = Modulus of elasticity in lbs. per sq. in.
P = Load at elastic limit in lbs.
D = Deflection in inches at elastic limit.
Other symbols as above.

Horizontal Shear at Neutral Axis:

$$V = \frac{3P}{4bd} \text{ where,}$$

V = Horizontal shear at neutral axis, lbs. per sq. in.
P = Maximum load in pounds.
Other symbols as above.

Specimens Tested in 1912.

NOTE: Odd number is the untreated half of a stringer and the following even number is the treated half.

Compression Parallel to Grain:

Load in lbs. per sq. in.:

$$S = \frac{P}{A} \text{ where,}$$

P = Applied load in lbs.
A = Area of section of test piece in sq. in.
S = Load in lbs. per sq. in.

Modulus of Elasticity:

$$E = \frac{PL}{AD} \text{ where,}$$

P = Load at elastic limit in lbs.
D = Deflection in inches at elastic limit.
E = Modulus of elasticity, lbs. per sq. in.
Other symbols as above.

Compression Perpendicular to Grain:

Load in lbs. per sq. in.:

$$S = \frac{P}{A} \text{ where,}$$

A = Area of compression plate in sq. in.
Other symbols as above.

The elastic limits were taken from the curves.

Data.—The results are shown in the tables. The summary sheets group the results of untreated specimens tested in January, 1911, with the treated specimens of the same timber tested in January, 1912. Specimens 13, 14, 39 and 40 were special tests made in January, 1911, and results obtained are not shown in the general summaries of specimens tested in January, 1911.

UTILIZATION OF SEWAGE SLUDGE.

It is only at rare intervals that an inventor has the good fortune of seeing a successful practical application of his idea within a few months of his experimental work. Among the few who may claim this honor is the name of Dr. J. Grossman, an eminent Manchester chemist.

His patented and simplified process for the utilization of sewage sludge (as described in some detail in The Canadian Engineeer of January 25th, 1912, page 210), has been installed in the Corporation of Oldham, near Manchester, and, as far as may be ascertained, is operating as a complete success, the sewage of the municipality being effectively disposed of and the by-products being not only marketable, but in brisk demand.

When this system is in operation the sludge is conveyed from settling tanks to the top of a three-story building by means of chain buckets, and is directed to six large cylinders on the top floor by the agency of several large sheet metal pipes. Each cylinder is encased with brick and heated, while revolving paddles within the cylinder move the sludge slowly along in order that the treatment may be effective. As the sludge moves along it is thoroughly dried, and may, if desired, be removed from the tanks at this stage as a dry, dark powder, highly inflammable, and entirely suitable for use as a crude fuel. The Corporation of Oldham do not consume their sterilized waste in this matter, but treat it further, and for this purpose each dryer has placed below on the ground floor a retort connected with the dryer by metal conduits. The dry matter falls to the retorts and is automatically mixed with a little acid and a quantity of superheated steam, which, in conjunction with the acid, re[illegible] the [illegible] [illegible] into the cooling towers, where it is condensed, and the grease, which floats on the water, is easily removed.

The process is automatic from the time the sludge is settled in the tank till the finished fertilizer leaves the retort, all the necessary labor consisting of a few men to attend the boilers and the fires under the drying machines and retorts. No fumes can escape into the atmosphere, and no features that might be considered a nuisance are found. The building in which the plant is housed has a length of 120 feet, a width of 45 feet and a height of 30 feet, and the cost of the plant for a population of 120,000 was only $60,000.

The matter removed from the retorts may be easily stiffened up into a high-grade fertilizer by the addition of potash and ammonia, and contains many advantages over raw sludge as a fertilizer, inasmuch as it is sterile and does not clog up the pores of the ground. Prize roses and other exhibition flowers have been grown in it with success in England, and other European countries are investigating sample shipments with a view of steady purchases. The grease recovered from the plant at Oldham has an estimated value of $6,000 per year.

THE BEARING POWER OF MOIST BLUE CLAY.

In a paper read before the Western Society of Engineers Mr. Edwin Hancock gives the results of tests in the Loop District of Chicago on the bearing power of moist blue clay.

The following tests were made in March, 1911, in the manner described:

Two openings about 8 ft. square were made in the concrete floor of the basement of the Federal Building, and the soil was excavated for a depth of 6 ft., so that there was a bearing on the original clay which had never been disturbed. On this clay a grillage was built up of planks 2 in. by 12 in., 2 ft. long. These planks were laid closely together so as to give a bearing of 4 sq. ft. This grillage was built up about 1 ft. high, and upon this was placed longer planks, upon which the load of pig iron was placed.

The settlement was taken by means of a wye level and rod. Readings were taken as soon as each load was put on, and then again after giving an hour for settlement. If no further settlement had occurred, a larger load was placed upon the plank. If the settlement had increased, readings were taken until they showed that the settlement had ceased.

The elevation above city datum of the street opposite this test was 14 ft., and the elevation of the clay upon which this test was made was 0.00. The lateral distance between the tests was 150 ft.

Following is a list of the loads and settlement:

Test No. 1.

Load per sq. ft. in lb.	Settlement.
1000	3/16 in.
2000	1/2 in.
3000	1 3/16 in.
4000	1 3/4 in
One-half hour later, 4:30 p.m., same load	1 7/8 in.
Next day; same load	1 7/8 in.

Test. No. 2.

500	No settlement.
1000	3/32 in
2000	7/64 in.
3000	3/16 in.
4000	3/8 in.
One hour later	7/16 in.
Two hours later	29/64 in.
Four weeks later, 4:00 p.m.	5/8 in.
Next day, 9:00 a.m.	15/16 in.
4:30 p.m.	15/16 in.

WINNIPEG WATER.

It will be remembered that a short time ago Professor Slichter presented a report to the Public Utilities Commission on the water supply for the city of Winnipeg. An abstract of this report was presented in *The Canadian Engineer.* Professor Slichter, in a recent communication to the Public Utilities Commission, states that he will not be responsible for the increase of the city's water supply unless his recommendations as presented in his report are carried out. He adds that the City Engineer of Winnipeg is plainly aiming to extend the water system to Crystal Springs without regard to his recommendations.

Col. H. N. Ruttan has acted as City Engineer of Winnipeg for a number of years, and his administration throughout has been most able and efficient. It is, therefore, with a certain reluctance that we view Prof. Slichter's strictures on the City Engineer's course in the extension of the well system for the immediate supply of the city. Col. Ruttan points out many inconsistencies in the original report, and quotes from his own experience to show that the report is not based on facts. The question is too long and too involved to be taken up at any length here. It appears to us, however, that Prof. Slichter should proceed more cautiously and conservatively in his comments and criticisms of City Engineer Ruttan, whose past experience with the water situation at Winnipeg makes him eminently well qualified to deal with the question. The conviction is forced upon us from an analysis of the report and the comments of the City Engineer upon it, together with the added protests embodied in Prof. Slichter's letter, that the original report as presented by Prof. Slichter was hazy and contradictory, and his subsequent recommendations have not improved it.

◆

TORONTO HARBOR IMPROVEMENTS.

The plans for the improvement and development of Toronto harbor have been prepared and presented to the Government and the City Board of Control. A description of the work to be done under these plans will be found in this issue.

The Commission, with its engineer and secretary, are to be congratulated on the very thorough and comprehensive manner in which the whole problem has been analyzed and presented in their report.

As everyone who is at all acquainted with the conditions in the present harbor knows, there has been a great neglect in the past to realize the potentialities of its location and natural advantages. Nature has been kind in providing a magnificent natural harbor, almost perfectly protected from storms, and of easy access. The city officials in the past have been far-sighted enough to preserve the water front under public control. These facts, coupled with the conditions which exist at Ashbridge's Bay, where the shallow water and marsh provides an area easily reclaimable for industrial development, gave the Commission a magnificent opportunity, and this they have conserved to the full.

The Dominion Government grant, which has already been guaranteed, is $6,000,000. The city's expense, it is estimated, will total nearly $2,000,000; and the Harbor Commission will provide the balance, or $11,000,000, by issuing debentures. It is fully expected, and there is little question but what it will be realized, that the revenue from the rental for factory sites, dockage dues, etc., will be more than sufficient to carry the necessary interest charges and the expenses of administration.

The improvements fall naturally under two main divisions, industrial and aesthetic. The industrial development includes a uniform depth of twenty-four feet of water in the harbor, east and west end docks, piers, a most complete system of railway sidings at Ashbridge's Bay, and a ship canal and turning basin in the factory area. Facilities will be given for complete co-operation of railways and vessels in the handling and transhipment of freight.

The aesthetic features include boulevard drives, bridle-paths, eleven miles of sheltered waterways, parks, walks, terraces, and a magnificent lagoon treatment at the Island. From the extreme east side of the city to the extreme west, at the Humber, the waterfront will be protected, improved and developed to give the maximum of aesthetic and recreative features. The chairman of the Harbor Commission, Mr. Lionel H. Clark, has associated with him on the Board Mr. R. Home-Smith and Mr. T. L. Church, representing the city; Mr. R. S. Gourlay, representing the Board of Trade, and Mr. F. S. Spence, representing the Government. Mr. E. L. Cousins is the Engineer and Mr. A. C. Lewis, Secretary of the Board.

THE ST. JOHN RIVER IMPROVEMENT.

The International St. John River Commission, a body of men appointed by the governments of the United States and the Dominion of Canada to investigate and report upon the conditions and uses of the St. John River, has received from its Board of Consulting Engineers a report on the possibilities of water storage and channel improvement on the river. As is well known, the St. John River forms an important part of the south-eastern boundary of Canada. For some years past there has been considerable trouble along the river due to the fact that the river is used to a great extent for the lumbering industry.

We hope to publish an abstract of the report in an early issue of *The Canadian Engineer*. The report covers the area comprising the watershed of the St. John River, and suggests a system of water storage and channel improvements which, if the report is acted upon, will doubtless do much to improve present conditions. If the plans outlined by the Board of Engineers meet with the approval of the Commissioners, an outlay of some millions of dollars will be required, which would be jointly met by the Canadian and the United States governments.

It is expected that the International Commission will make their final report to their respective governments in a short time, and this report of the Board of Engineers will form an important part of the final report.

THE ROAD BOARD OF GREAT BRITAIN.

We note in a recent issue of an engineering contemporary in the Old Country some rather severe criticisms of the Road Board and its consulting engineer. The facts as outlined appear to justify criticism.

In answer to certain questions raised in the House of Commons on October 17th, the Chancellor of the Exchequer replied that the salary paid to the consulting engineer to the Road Board is $3,300 a year, out of which he provides his own office and staff. It was also stated that he carries on his business as a consulting engineer on his own account; that he has no interest in the two road companies which were named, but that he frequently acts as consulting engineer for them; that he had invited a party of road engineers to inspect the work of road construction being executed by a certain company, which invitations were printed on paper with the heading, "The Road Board." The Chancellor explained that as consulting engineer to the Board, Colonel Crompton's advice was taken on technical questions, but that he had no executive or general duties.

As our contemporary holds, it is manifestly impossible to expect that an impartial judgment can be given by the Road Board regarding the experimental roads which have been laid by different manufacturers and contractors for the Board, now that it is known that the consulting engineer for the Board also acts for one or more of their competitors, that he is also a patentee for a road-surfacing method, and has, moreover, laid down a length of road to his own specification for the Board.

With the facts as stated, the journal in question is to be congratulated on giving publicity to the fact. It is quite probable that no intentional harm was intended is allowing such a state of affairs. At the same time, such irregularity of administration should be corrected at once.

EDITORIAL COMMENT.

A writer in The Saturday Evening Post describes the trials and troubles of a technical man whose stenographers, and he had several at one time and at different times, insisted on transcribing their notes incorrectly. He would say: "The tube wall is stressed circumferentially," and the letter would read: "The tube wall is dressed reverentially." Or, "A wattmeter in use" would come out as, "What's the matter with us." "Synchronizing force" appeared as "A singing icicle farce"; and "Helical reducing gears" showed up one day disguised as, "Hellish reducing tears." The editor of the paper has had his troubles with the rest of them, but he doffs his hat to the above.

* * * *

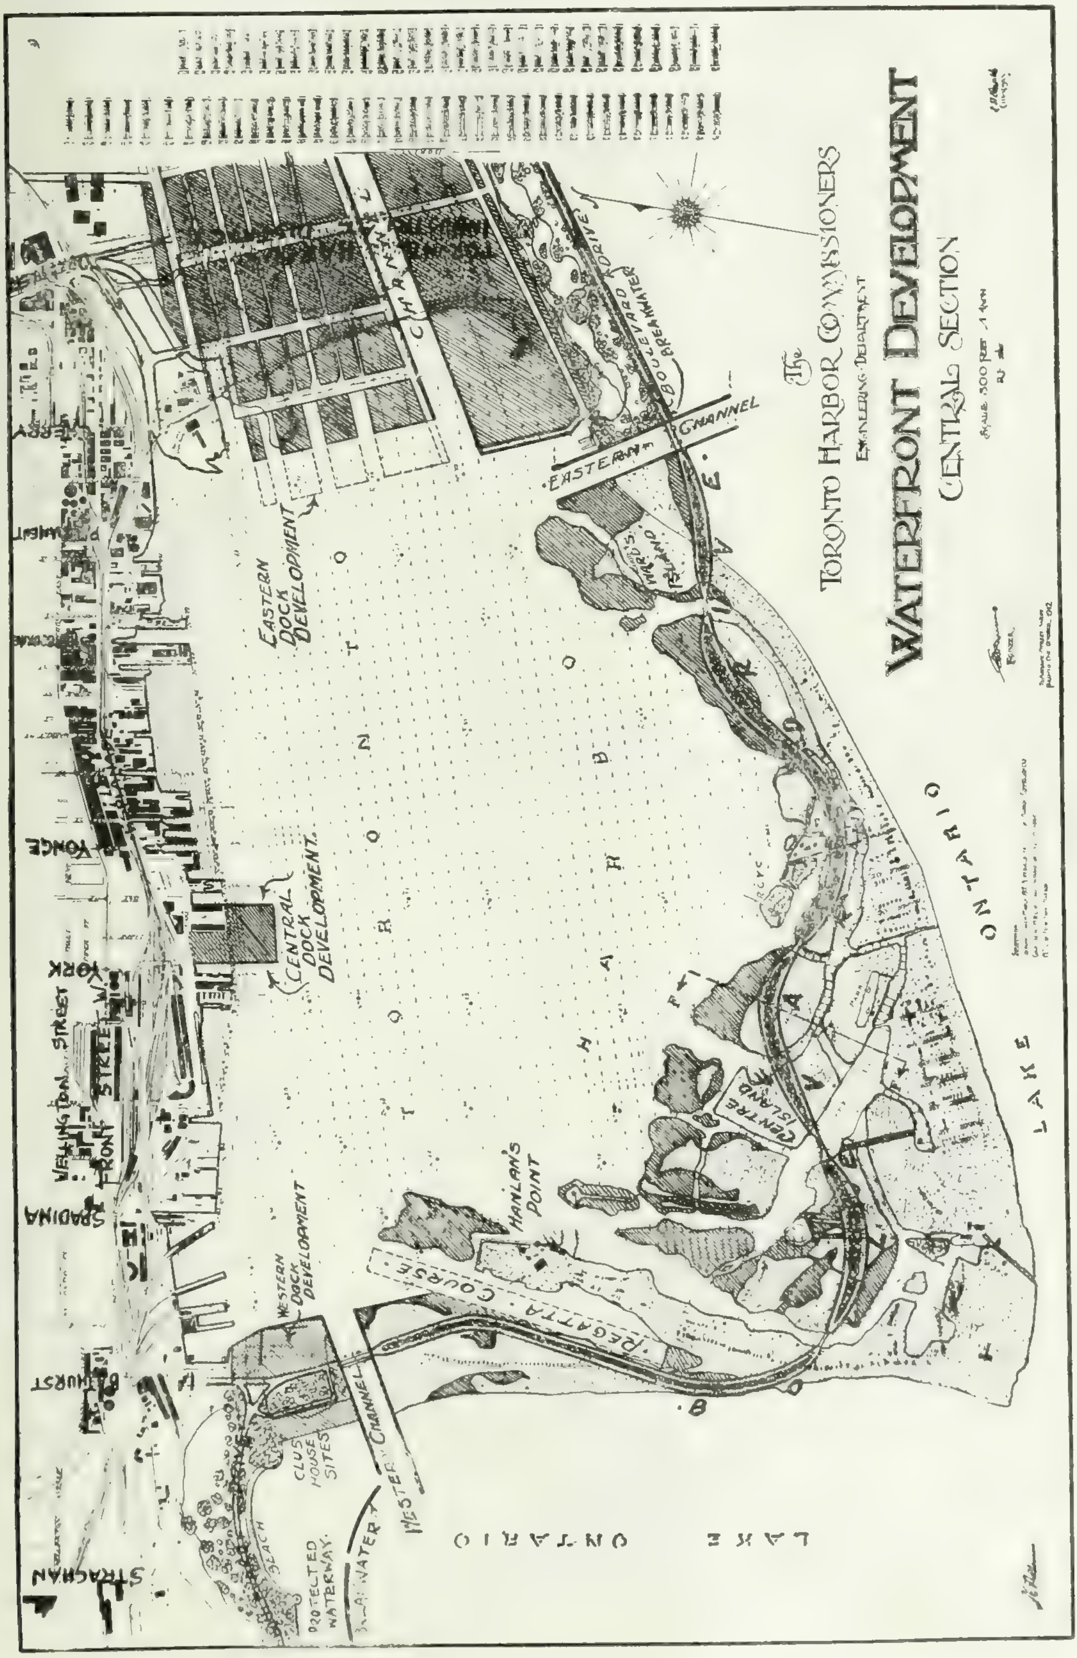
Two special offers deserving of editorial mention are those made by *The Canadian Engineer* to old and new subscribers. The balance of the copies of the paper for 1912 will be forwarded free of charge to all new yearly subscribers who mention this special offer. And, in conjunction with this, the book offer, outlined on another page, holds good. To present subscribers who send in new subscriptions, which may have the advantage of the above terms, will have their subscriptions extended three months without charge for each new subscription they add to the list.

INDUSTRIAL ACCIDENTS.

According to the record of industrial accidents maintained by the Department of Labor, there were 104 workmen killed and 324 injured during the month of October. Compared with the record for September, this is an increase of fifteen in the number killed and a decrease of ninety-five in the number injured. The greatest number of fatal accidents occurred in steam railway service, there being 28 employees killed. The building trades come next with 18 fatalities. Of the non-fatal accidents, the greatest number occurred in the metal trades, the number recorded being 85, followed second by building trades with 40 injured, and third by steam railway service with 37 injured.

TORONTO HARBOR IMPROVEMENT.

The Toronto Harbor Commissioners have presented to the city council the plan prepared by them for the improvement of the harbor and waterfront.



The plan, as finally adopted by the commissioners, provides for the proper treatment of the harbor, both from a commercial and industrial point of view, and also for the development of the aesthetic features of the waterfront.

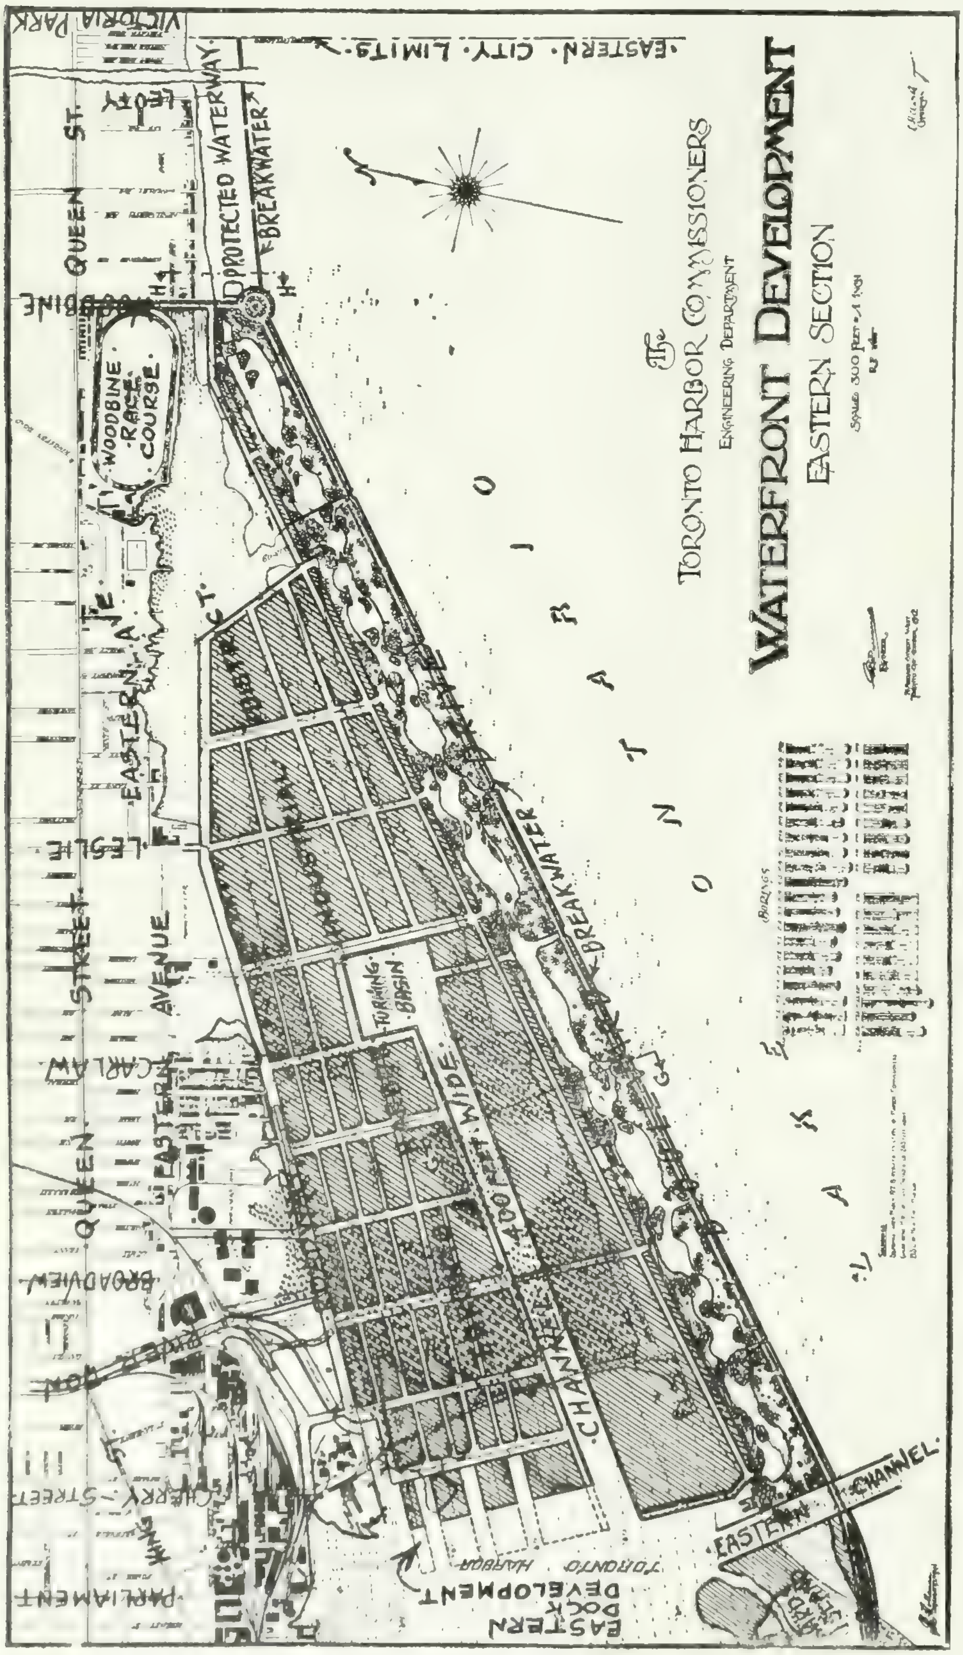
The commissioners, on taking office at the latter end of the year 1911, found themselves in charge of one of the finest land-locked harbors in the world, certainly the finest natural harbor on the Great Lakes, of which natural position very little advantage has been taken, and for the development of which no equipment had been provided.

The one redeeming feature in the past history of the harbor was afforded by the foresight of your city council and those councils which preceded it in securing for the citizens the ownership of 80 per cent. of the entire waterfront within the boundaries of the city, including a large portion of the waterfront on the inner harbor and all of the beaches and waterlots to the east and west of the Island.

With the object of securing definite information on which to formulate proper plans, the commissioners secured the services of Mr. E. L. Cousins as harbor engineer, and since the 1st of February he has energetically pushed forward the necessary preparatory work, a large staff of engineers and draughtsmen having been constantly employed. The sum of $27,000 has been spent in securing a complete survey of the waterfront from Victoria Park to the Humber River, and a hydrographic survey of the harbor, including 8,000 soundings to show the depth of water and borings to rock all along the waterfront and throughout the bay to determine the ultimate depth available and the nature of the material in which the various projected works will have to be constructed.

Upon the completion of the plans the city of Toronto will possess:

A modern harbor with a uniform depth of water capable of accommodating any vessel with a draught of 24 feet. Modern, permanent docks on the central waterfront served by 24 feet of water and equipped with the best of freight sheds, warehouses and appliances. A dock and industrial district at the foot of Cherry Street equipped with freight sheds, warehouses and the first of a series of factory buildings to serve the needs of the east end. A similar area at the foot of Bathurst Street to take care of west end business. Proper co-ordination of rail and water traffic at all three of the above points in order to properly develop the port. An industrial area containing 644 acres of available land in the Ashbridge Bay district, which will be known in the future as the Toronto Harbor Industrial District, capable of accommodating factory buildings with a value of $30,000,000 and producing a ground rent revenue of $500,000 per year. A ship-channel 6,800 feet long, 400 feet wide and 24 feet deep, with turning basin 1,000 feet square at its east end serving the Industrial District and the eastern portion of the city generally, and equipped with three miles of dockage. A dock area on the west face of the Industrial District capable of development so as to provide an additional dock frontage of three miles. A new lakefront park and waterway extending from the Eastern Channel to the foot of Woodbine Avenue, and containing 352 acres protected by a breakwater three miles long. Inside the breakwater will be ample accommodation for east end aquatic clubs. A protected waterway with an average width of 600 ft. behind a breakwater from Woodbine Avenue to the east city limits. Additional park areas on the Island totalling 352 acres. New park areas in the district from Bathurst Street to the Humber River containing 190 acres and fronting on a protected waterway 500 feet wide which is separated from the lake by a breakwater. A total area of new park lands of 894 acres. A bathing beach one and one-third miles in length, from Sunnyside to the Humber. A similar beach four and one-quarter miles in length from the Eastern Channel to Victoria Park. A lakefront boulevard system of driveways, bridle paths and walks across the waterfront for eleven miles. A protected waterway twelve miles in length, from east to west along the city front. A terrace promenade 6,880 feet in length and 55 feet wide, from Sunnyside to the Humber. A double-deck combined traffic and recreation pier 300 feet long and 20 feet wide in front of the Exhibition Grounds. A location for aquatic clubs 1,000 feet long and 300 feet wide north of the new Western Channel with an anchorage basin of absolutely protected water covering 42 acres. A similar location at the foot of Roncesvalles Avenue, 800 feet long and 250 feet wide fronting on the protected waterway formed by the western breakwater. A public playground covering 3½ acres east of the foot of Roncesvalles Avenue. A public square 600 x 300 feet west of Roncesvalles Avenue. A reservation, 80 feet wide, from the Humber River to Sunnyside crossing as a right-of-way for radial lines. A new Lakeshore Road, 66 feet wide, to the south of the radial railroad reservation.



In order to facilitate the handling of the work when active operations are commenced, the waterfront and harbor has been divided into three sections. The eastern section takes in the Ashbridge Bay district and the sandbar in front of it, the central section takes in the central waterfront from Parliament Street to Bathurst Street, the inner harbor and bayshore of the Island, while the Western section covers the waterfront from Bathurst Street to the Humber River.

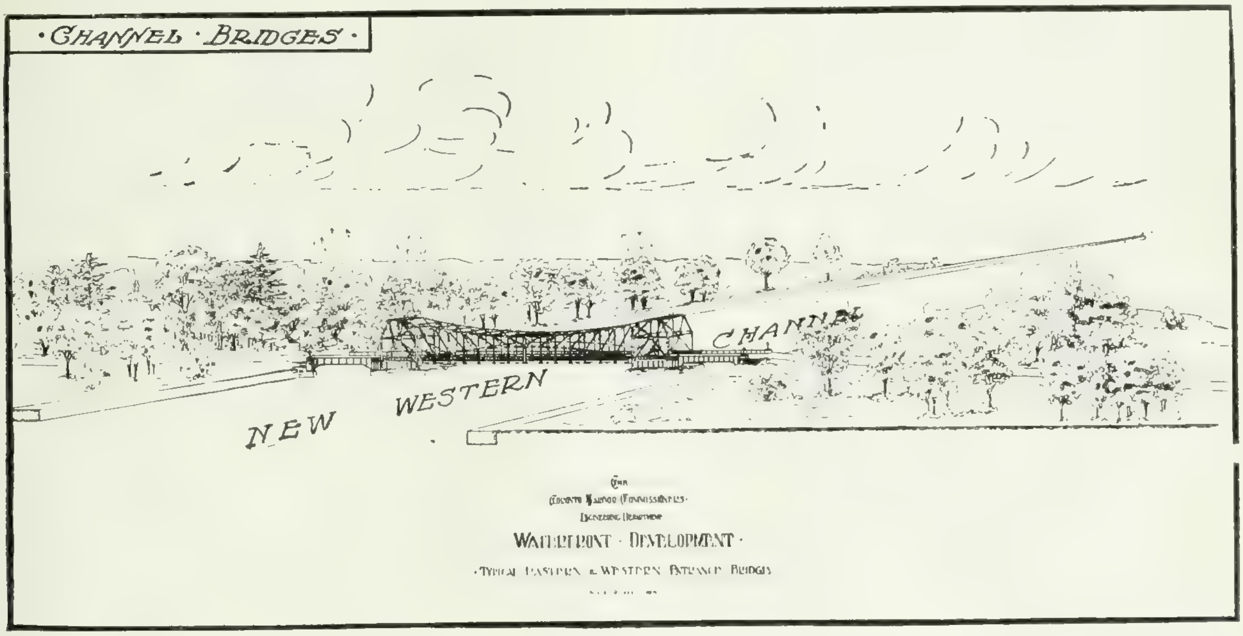
Eastern Section.—In the eastern section the development planned covers three phases, commercial and dock development, industrial development and park treatment on the laketront. A breakwater will be constructed an average distance of seven hundred feet out in the lake from the present shore and reaching from the eastern harbor entrance to the east city limits at Victoria Park. To fill the space behind this wall up to eight feet above mean water level, including the 1,000 acres in the industrial district, will require twenty-five million cubic yards of material. This material can all be secured from the bay and the bed of the lake and outside the breakwater, and the two large hydraulic dredges will be employed on this work.

The dredging operations will be on a larger scale than ever before attempted in Canada. Each dredge will be capable of dredging either sand or clay from a depth of 50 feet and pumping it for a distance of 4,000 feet through pipe lines from which it will be distributed to the area to be filled. The dredge will be built of steel and will be propelled by twin screws, and controlled by steam steering gear.

The machinery will be of 2,000 horse-power of the latest improved type and complete electric light and search-lights will be fitted so that work can be carried on at night as well as day. Twenty-five thousand tons of sand and clay per day can be dredged and delivered a mile distant by this dredge. This will be the most powerful dredge in America. Up to the present the largest Canadian hydraulic dredge is the "Tarte," built in Toronto in 1901, and working on the St. Lawrence ship-channel below Montreal, but this new dredge to be built will be double the power of the "Tarte."

Notwithstanding its great size and power, the dredge with its machinery will be under the control of one man on the bridge deck. Here will be located not only complete apparatus for navigating the ship, such as steering wheel, binnacle, engine-room telegraphs, etc., but also a battery of levers controlling all the movements of the dredging apparatus, with gauges indicating the depth of working and the amount of sand which is being picked up.

The dredge will be built from the designs and under the supervision of A. W. Robinson, M.Can.Soc.C.E., the well-known dredge expert, of Montreal, consultant on dredging to the British Admiralty.



·CHANNEL ·BRIDGES·

NEW WESTERN CHANNEL
The
Toronto Harbor Commissioners
Engineering Department
Waterfront · Development ·
·Typical Eastern & Western Entrance Bridges

A ship-channel will be constructed for the purpose of extending the inner harbor into the new industrial district. This channel will be 6,800 feet long, 400 feet wide and 24 feet deep, and will terminate in a turning basin 1,000 feet square, and the sides of both the channel and turning basin will be so constructed as to form three miles of dockage accommodation. The industrial area, when completed, will contain 644 acres of land for factory sites, 235 acres of streets and railroad reservations, and 130 acres of waterways.

The roadways will have a minimum width of 75 feet and a maximum width of 175 feet. The district will be served by railway tracks connecting with all the railways and the railway layout has been so arranged that every alternate street will be free from tracks.

The western, or bay face of the district will be developed for dock purposes as the district grows, and will ultimately add 2½ more miles to the dock frontage of the areas, as shown on the plan. One large dock is now being constructed and will be equipped with modern freight sheds and one storage warehouse and the beginning of a series of factory buildings will be erected back of the dock.

The mouth of the Don will be diverted from its present outlet to a new outlet into a slip at the foot of Cherry Street, and the original Don Channel, now filled up, will be utilized as the location for a highway entrance to the industrial area.

The area north of the ship-channel will be reserved for light manufacturing plants, the area to the east will be the home of heavier plants which do not require direct water service, and the area south of the channel will be utilized for the heaviest class of manufacturers requiring a frontage direct on navigable water. The width of the channel, 400 feet, will allow a vessel of the largest type to safely pass through it between two vessels of equal size tied up at each side.

Along the south portion of the reclaimed land a park area 1,000 feet wide will be reserved, fronting directly on the breakwater. Immediately to the north of the breakwater will be the lakefront boulevard drives and walks with a park and lagoon treatment north of the boulevard, and a fine beach to the north of the lagoon. Bridges at reasonable intervals will carry traffic across the lagoon to the lakefront.

and forty-foot openings in the breakwater at intervals of 2,000 feet will allow seawall craft to pass through from or to the lake. Inside the breakwater fronting on the lagoon will be ample sites for aquatic clubs and a strip of land will also be laid out, north of the park area, as a location for summer homes.

East of Woodbine Avenue there will be no park treatment, but the seawall will be carried to the east city limit, leaving a protected waterway for the use of the residents of this district and the public generally.

Central Section.—In the central section the work planned consists almost entirely of commercial and park development with some industrial land provided at the foot of Bathurst Street. The commissioners plan to spend the sum of $2,194,000 in the construction and equipment of proper docks in the area from Bay Street to York Street, and at the foot of Bathurst Street, but the details of construction for the central development cannot be worked out until the question of separation of railway and highway grades has been definitely settled.

At the foot of Bathurst Street a dock and industrial area of 17 acres will be provided north of the new Western Channel and east of the boulevard drive. This area will be served by 800 feet of dock with 20 feet of water and will be accessible to all railway lines.

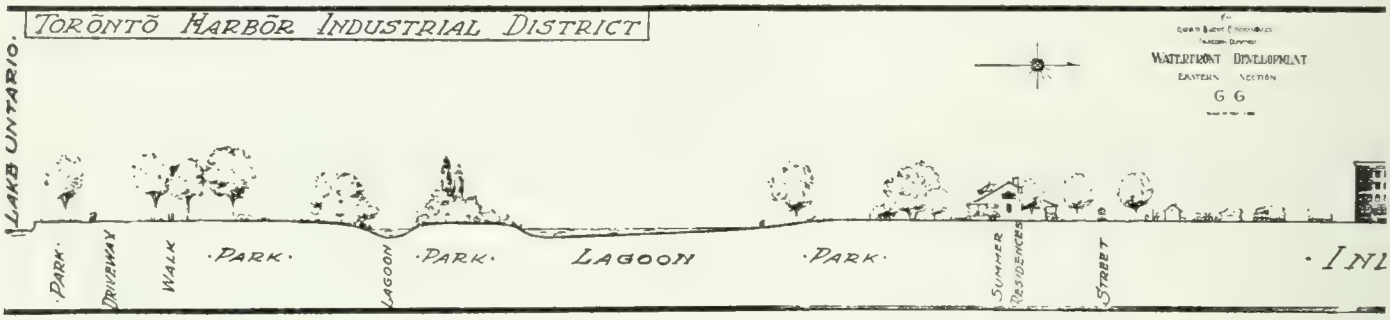
The commissioners propose to construct at this point modern freight sheds and storage warehouses and a factory building similar to the one planned for the eastern section. The balance of the work in the central section consists of the reclamation of 352 acres of additional park lands on the Island, a portion of which will serve as a location for the boulevard drive and the balance will improve the present unsightly portion of the Island. The boulevard drive will be carried from the east across the Eastern Channel by means of a roller lift bridge giving a clear entrance for boats of 200 feet.

Western Section.—From Bathurst Street to the Humber River the treatment is entirely along park lines, there being no provision for commercial development. A breakwater will be constructed from a point of 200 feet west of the new channel to a point at the mouth of the Humber River and distant an average of 900 feet from the existing shore line. Inside this breakwater will be a protected waterway with an average width of 500 feet reaching from the Humber to Bathurst Street and linking up with the Island lagoon system and the new lagoon system planned for the eastern section to form a complete protected waterway across the entire city front.

The western breakwater will be broken every 2,000 feet by forty-foot openings to permit of the egress or ingress of sailing or other craft.

From Bathurst Street to the Exhibition Grounds and from Cliff Road to the Humber the sand pumps will be utilized to reclaim areas of property for park purposes and from Sunnyside to the Humber over a mile of fine sand bathing beach will be made and a bath-house erected at its east end. In the same district sufficient land will be reclaimed to provide for an 80-foot reservation for a radial railway entrance to the city along the location of the present Lakeshore Road with a new 66-foot commercial road to the south of the reservation. This roadway will replace the Lakeshore Road and will serve as the business entrance to a tier of lots reserved for building purposes. In front of this tier of building lots and 8 feet above the boulevard proper will be a terraced boulevard and walks 55 feet wide, faced by a parapet wall and with steps at intervals leading onto the boulevard proper. Outside the boulevard and bridle paths will be the bathing beach and protected waterway with the breakwater as its southern boundary.

The Cost.—The total cost of all the work planned by the commissioners amounts to $19,142,088. This expenditure it is intended to spread over a term of years, the expectation of the commissioners being that the work will be completed within ten years.



The city is asked to undertake the expenditure of $146,500 as its share of the general work for the purpose of constructing the highway bridge across the Don Channel into the Industrial District and the construction of a retaining wall and balustrade along the front of the Exhibition Grounds in order to separate the grounds from the boulevard. This expenditure will have to be followed later on by an expenditure of $1,656,383 by the city if the lakefront boulevard plan is approved and the city undertakes to complete it by constructing walks, roadways and park features after the commissioners have reclaimed the site. This makes a total expenditure allotted to the city of $1,802,883 as its share of completing within ten years the work shown on the plan.

The Dominion Government has been asked to undertake the expenditure of $6,123,284 in the construction of the eastern breakwater, the western breakwater, the ship-channel in the industrial district, the bridges over the eastern and western harbor entrances and the bridge over the ship channel and protection piling near the eastern channel.

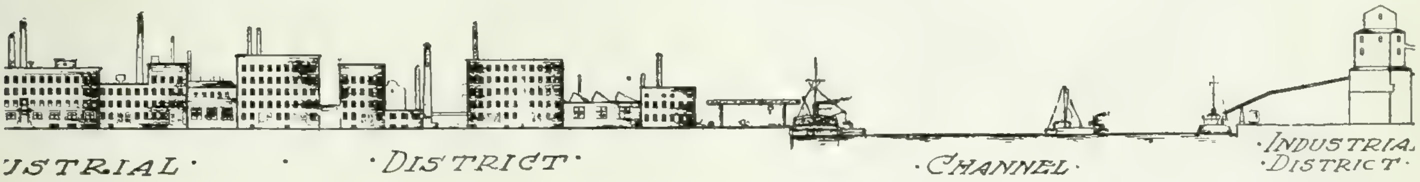
The balance of the projected work will be undertaken by the commissioners at an estimated cost of $11,215,920. The money will be raised by the issue of debentures by the Harbor Commissioners and a careful estimate of the business possibilities of the plan warrant the assurance that the ultimate annual revenue from the property entrusted to the commissioners and created by them will be such as to meet the interest and sinking fund charges on the money borrowed and to leave a handsome surplus to be handed over to the city to aid in the reduction of the tax-rate.

The city is asked to undertake the portion of work allotted to it and to intimate its intention of joining in the construction of the boulevard drive.

If the city joins in the boulevard construction the commissioners will create the land necessary as a location for the drive and will ask the city to pay for the use of this location an annual rental equal to the interest and sinking fund charges on this part of the work.

The city is asked to intimate its intention of taking over the areas reclaimed for park purposes on a similar arrangement. It has been estimated that the total annual rental to be paid by the city for these park areas and the boulevard location will amount to $153,833 and in return for this the city will receive an addition to its park area of 894 acres.

The plans of the commissioners provide for the extension of Bathurst Street southerly in a straight line from Front Street with a width of 100 feet and an arrangement has been made with the Canadian Pacific Railway Company under which they join in this extension and consent to the south ramp of the necessary bridge being carried over their property. This will provide also for an adequate eastern entrance to the Exhibition Grounds and it will be necessary for the city to undertake the expropriation of the property north of the Canadian Pacific Railway property necessary for the street extension.



SUMMARY OF FILLING, PILING, ETC.

Filling.—Eastern section industrial eastern entrance to Woodbine Avenue, 22,714,144 cubic yards.

To be reclaimed to 8 feet above mean water level property, 9 per cent. of which is now under water, reclaiming 900 acres.

Eastern section, park and lagoon treatment, eastern entrance to Woodbine Avenue: Filling 5,042,045 cubic yards to 8 feet above mean water level, reclaiming 352 acres.

Central or Island section, Parliament Street to Bathurst: Filling 4,267,600 cubic yards to reclaim 350 acres of park lands to elevation 6 feet above mean water.

Western Section, Bathurst to Humber River: Filling 3,942,649 cubic yards to make 190 acres of park lands.

Summary.

	Cubic yards.
Industrial	22,714,144
East Park	5,042,045
Central	4,267,600
West	3,942,649
	35,966,438
Say,	36,000,000

Available material between eastern entrance and Woodbine Avenue	27,535,486
Available in Toronto Bay	18,000,000
In vicinity of Humber Bay	4,447,476

Summary.

East	27,535,486
Centre	18,000,000
West	4,447,476
	49,982,962

Composite Steel and Concrete Piling, Dock Work and Retention Piling for Boulevard Treatment.

Eastern Section: Four miles of retention piling and dock work, including ship channel, turning basin, marginal way on bay face and north slip.

East Section, Park and Boulevard: Breakwater and composite pile protection work.

Eastern entrance to Woodbine Avenue	17,350 ft.
Woodbine Avenue to east city limit	6,600 ft.
Total	23,950 ft.

Western Section, Bathurst Street to Humber River:

Retaining wall	6,880 ft. long
Exhibition dock	300 ft. long
Breakwater and composite pile protection work	20,000 ft. long

Bridges.—Suggested eastern and western entrance bridges are of the Scherzer roller lift or Strauss bascule type, 60 feet wide, providing for street railway, vehicular and pedestrian loading, a similar type of bridge is contemplated for the crossing of the ship-channel, excepting that this bridge will provide for steam railway, street railway, vehicular and pedestrian traffic, with width of 60 feet.

One bridge over the River Don diverted 80 feet wide.

Eastern Section—Boulevard Drive:

Seven vehicular bridges, 40-ft. span, 80 ft. wide.

One 100-ft. span, 80 ft. wide, vehicular.

One 100-ft. span, 56 ft. wide, vehicular.

One 40-ft. span, 56 ft. wide, vehicular.

Seven foot bridges, 50-ft. span, 10 ft. wide, for crossing lagoons.

·Typical Island Pedestrian Bridges·
Central Section

Central Section:

Ten 50-ft. pedestrian bridges (arch).

Three 120-ft. arch pedestrian bridges.

Three bridges 180 ft. over all consisting of two 50-ft. arch spans and one 80-ft. arch span, providing for street railway, vehicular and pedestrian traffic.

One 100-ft. arch span, providing for street railway, vehicular and pedestrian traffic.

Four 40-ft. spans for boulevard drive over lagoons.

Western Section:

One 400 ft. concrete arch foot bridge connecting main land with proposed Exhibition dock; bridge to be 10 ft wide with 30-ft. arch spans.

MONTREAL'S WATER DEPARTMENT

The charges which the Canadian Fire Underwriters of Montreal recently made against the city's water department have been the subject of considerable discussion at the city hall. The charges were of a somewhat serious nature, and accompanying them was a request for an investigation of a thorough character to be made into the conduct of the water department generally.

Alderman Lapointe, one of the oldest members of the city council, in referring to the charges made by the underwriters, said:

"It is stated in this resolution that in the management of the water department there has been incompetency; faulty construction of engines; faulty workmanship; acceptance and use of inferior materials, and continued dilatory work and repeated disaster to the city water plant. Such a list of charges are serious, and there is no other course open to the city but to grant the investigation the underwriters desire. The charges are sweeping, and the allegations are direct. Whether or not they are justified we shall know when experts are appointed to look into the matter."

Alderman Lapointe admitted that there had been many accidents to the water system, but claimed that of recent years the facilities had been improved considerably, and he considered that the best way to proceed on the charges would be to ask the board of control to study the subject and to report the results.

At a later meeting of the council the board of control reported that it could not see any advantage in having the investigation. Controller Godfrey said that some of the accusations were certainly not correct, and that the pump which the underwriters stated had arrived in June, and had been left lying around for months, was now almost ready to be operated. The fact was that the works where the pump was being manufactured had met with an accident and portions of the machinery had not been received until a short time ago. It was this which delayed the setting up of the pump and not any fault of the city or water department. He did not consider that there was any necessity for a commission as the situation was well known to them.

When the council came to consider the matter, however, they decided by a vote of twenty-three or four to have an investigation carried out. This action meets with general approval. The condition of affairs which has existed here during the past three or four weeks has certainly been anything but of a character to inspire confidence in the department, more especially when it is remembered that for years past, something of a more or less dangerous character has been frequently taking place.

The Worthington pump, the breakdown of which caused the recent water famine, has been repaired and is in operation. It has a capacity of 12,000,000 gallons daily so that this will go a long way towards putting the reservoirs in a condition once more to supply not only the necessary household consumption, but to provide against any lack of pressure, in case of fire, such as was so serious recently in Montreal. The new pump, to which the underwriters referred, will shortly be ready to operate. It has also a capacity of 12,000,000 gallons per day. The situation should then be much better in Montreal, as if one pump fails, the other will be ready to take up the work. The claim is frequently heard that the trouble arises very largely through provision not being made in advance for the increased requirements of the city. These increases have been great of late years, and the investigation will now show whether foresight has been lacking or whether the department has been alive to the city's requirements.

◆

ONTARIO'S LARGE MINERAL OUTPUT

Ontario continues to make important mining history According to the returns for the nine months ended September 30th, 1912, furnished to *The Canadian Engineer* by the provincial bureau of mines, the production has been as follows:—

Product.	Quantity.	Value.
Gold, ounces	53,488	$ 1,117,335
Silver, ounces	22,231,451	12,707,826
Copper, tons	8,019	1,142,076
Nickel, tons	15,907	3,368,437
Iron ore, tons	37,265	101,284
Pig iron, tons	452,021	6,051,978
Cobalt in crude material, pounds	711,180	176,786
Cobalt and nickel oxides, pounds	711,180	176,786
White arsenic, pounds	2,944,104	66,316

The yield of gold for the first nine months of 1912 is more than double in value that of any preceding twelve months. The bulk was from the Hollinger and Dome mines. Other contributors were the McIntyre and Vipond at Porcupine, and the St. Anthony at Sturgeon Lake. The Cordova mines in Hastings county and the Olympia at Lake of the Woods also turned out bullion.

As compared with the corresponding period of 1911, the production of silver was 963,601 ounces less in quantity, but $1,114,090 more in value, silver being now much higher in price than last year. The productivity of the silver mines of Cobalt is being well maintained. The shipments comprised 15,408 tons ore, 7,859 tons concentrates and $2,239,124 in bullion. South Lorrain contributed 616,692 ounces to the total and Gowganda, 449,281 ounces.

The mines of the Sudbury district yielded 15,907 tons of nickel as compared with 12,711 tons during the same period last year, and 8,019 tons of copper as against 6,769 tons. Both these metals are estimated in the form of Bessemer matter produced by the blast furnaces, constituting together about 80 per cent. of the matter by weight.

Considerably less iron ore was shipped during the nine months of 1912 than during the same period of last year, the reduction amounting to 135,603 tons. The Helen mine was the principal producer. On the other hand, the output of pig iron shows a large increase, being 452,021 tons as against 296,856 tons last year.

The refining works in Ontario produces arsenic, cobalt crude materials or residues, and the oxides of nickel and cobalt. Shipments amounted in value to $300,716 as compared with $125,907 for the corresponding period of 1911. Both the European and American market for cobalt oxides are now for the most part supplied by the product made from the ores of Cobalt.

CHINA CLAY PRODUCTION IN DEVON AND CORNWALL, ENGLAND.

By W. S. Harvey, A.M.Can.Soc.C.E., A.M.Inst.C.E., A.M.I.M.E.

[Mr. Harvey, who is assistant to the City Engineer of Lethbridge, Alberta, has prepared this paper on the collecting and treating of China clay in England. As China clay has lately been discovered in British Columbia, this discussion will, no doubt, be of interest to our readers.—EDITOR.]

The Industry.—The china clay industry is carried on in Devon and Cornwall to a very great extent, in fact china clay production and lead and tin mining are Cornwall's largest industries. It is well known that grey granite has been quarried in these two counties for many years, and the felspar in this granite, when in a state of decomposition, is in reality the infant state of that valuable commercial product known as kaolin or china clay. This decomposition is caused by the granites becoming dissolved by rainwater which is charged with carbonic acid, collected as it passes through the various substances, such as decayed vegetable matter, etc., forming the surface or overburden. The following is a brief description of the various stages through which it passes before reaching the potters' hands.

Sinking Clay Pits.—In these two counties the decomposed granite lies about five or six feet below the surface, the first operation in sinking the clay pits being to remove the overburden. This is usually carried out over an area of about half an acre for each proposed pit. A pumping shaft is then sunk to the full depth of the clay beds, often approaching one hundred feet; from the bottom of the pumping shaft, adits or tunnels are driven horizontally in various directions and for varying distances. At the ends of these adits, upcast shafts are driven to the surface. The adits are driven on a slight upgrade, so that the clay liquid may drain to the sump of the main pumping shaft. Upon completion of the driving of the upcast shafts, a large wooden launder is built to the full depth of each shaft; these launders are constructed of three-inch planking, in the sides of which holes are bored from top to bottom, and stopped with moveable plugs. When the launders are in position the shafts are filled in round about. A leat or ditch is now dug surrounding the site of the proposed pits, being fed with water from adjacent streams and provided with penstocks at points around the pits.

Washing Clay.—Twenty or thirty men are employed at each pit and as the water is allowed to run over the clay beds, the clay is scraped and worked with tools, the clay liquid finding its way through the launders and adits to the main pumping shaft. As the pits get deeper the plugs are removed from the launders. The clay pits, after being worked for about ten years, will increase in area to many acres and develop into one large pit, the overburden being removed as required. The clay liquid is pumped, by means of a Rocker pump, through a rising main, thence through a vitrified pipe line it gravitates to the mica drags.

Mica Drags.—These consist of a series of shallow tanks, their duty being to arrest the mica, sand and other foreign matter from the clay liquid, which enters the drags at a sand bay provided with screens and baffles; here the greater part of the sand is removed. The sand bay is divided into two compartments so that cleaning may be carried on without stoppage of the flow. The liquid next enters the mica drags proper; these are usually about one hundred feet long and fifty feet wide, being divided longitudinally into narrow channels, each eighteen inches wide; the division walls being of brick on edge and faced with two-inch lumber. The channels are separated from the sand bay by hand sluices. The mica drags are not baffled in any way as the velocity of the liquid is so reduced that any particles of mica and remaining sand will deposit themselves on the floor of the drags. The drags are cleaned out about once every week, the sand and mica being sold for plastering and other building purposes.

Concentrators.—Upon leaving the mica drags the liquid continues on its journey through the pipe line to the concentrators. These are circular tanks about forty feet in diameter with granite masonry walls and a conical bottom of granite pitching. The concentrators are, as a rule, built in a battery of 8 or 10, and are so arranged that the liquid can be drawn off from any one or all of these as required; there is also a by-pass and valve on the pipe line to shut off all the tanks, the liquid then flowing to other concentrators further down the line. The duty of the concentrators is to take off the surplus water, this being accomplished by means of a floating valve. When pumped from the clay pits, the liquid contains on an average 5 per cent. of clay and 2 per cent. of mica and sand in first quality clay, and about 4 per cent. of mica and sand in clay of second quality. Concentrators are, therefore, placed wherever convenient along the pipe line to take off all the surplus water possible.

Clay Silos.—The silos are of rectangular form, built with granite masonry walls and a granite pitched bottom sloping down from back to front. At the bottom of each front wall is a large aperture provided with a penstock operated from a platform above. The silos are built in a battery of 15 or 20 arranged in tiers, the number being of course governed by the required output of dried clay. The clay liquid now having passed through the concentrators, on arriving at the silos, is greatly reduced in its percentage of water. It now enters the silos and as a silo becomes filled it is allowed to settle for two or three weeks, when as much as possible of the remaining water is drawn off, this being done by means of peg launders, the pegs being removed as the clay settles and the top water drawn off.

Kilns.—The kilns are situated in immediate proximity to the lowest tier of silos, the kiln floors being on a level with the apertures in the silo walls. These are from one hundred to one hundred and fifty feet long with the furnaces at one end, and the flues running to a stack at the other end of the building.

As soon as the clay in a silo is ready to be dried, the penstock is opened and the clay allowed to run over the kiln floors, the clay at this stage containing about 30 to 35 per cent. of water. It is now heated and when dried sufficiently is cut by wooden tools into convenient blocks for handling, the heating process still continuing until thoroughly dry, when the clay is removed by a belt conveyer and stacked under cover, or loaded direct into cars for shipment to the potteries. The kilns are provided with an ample supply of ventilators to take off the steam during the drying process.

It will be noticed that from the clay pits to the kilns it is a process of gravitation with the exception of the pumping and in some clay works, where sufficient fall from the pits can be obtained, even this is disposed of. Several of the Devon clay pits are situated five or six miles from the kilns, in fact one of the latest works opened up has a pipe line of nine miles in length.

All hand sluices, weirs, baffles and other details are constructed of galvanized metal or wood to prevent any possibility of the clay being discolored by rust, as it is absolutely essential that china clay of first quality should contain no traces of discoloration.

DESIGN OF TURNTABLES FOR HEAVY LOCOMOTIVES.

Recent developments in the design of locomotives, accompanied by great increase in weights and changes in the distribution of weight on long wheel-bases, have introduced elements into the design and operation of turntables materially different from the problems of a few years ago. In view of these changes an exhaustive study has been made of present practice by a committee of the American Railway Bridge and Building Association, of which Mr. C. E. Smith, bridge engineer of the Missouri Pacific Railway, is chairman, and the results have recently been presented in a report to the association. A large amount of descriptive data regarding turntable design, construction and operation on fifty-seven railroads, aggregating 175,000 miles of line, is included in the report, and from this information the committee has formulated a number of general principles underlying present practice.

Length and Type of Table.—The committee found that in the past it has often been the practice to build turntables only long enough for engines actually in use, with the result that frequent enlargements have been necessary. Turntables now actually in use were studied in connection with the loading diagrams of the heaviest locomotives of the principal builders. It was found that for standard-gauge roads no future turntable should be built shorter than 75 ft., and that roads expecting to use the heaviest engines should adopt 90 ft. as standard. For engines having wheel bases longer than 90 ft. wye tracks should be provided unless special local conditions compel the use and justify the expense of a longer table.

The committee feels that the deck type of table is preferable to any other on account of low first cost, ease of operation and economy of maintenance, but sees no serious objections to through tables where conditions demand their use. Where through girders are used the best practice seems to favor providing supports for the ties by means of steel stringers and floor beams instead of using deep ties resting on shelf angles. The deep ties are expensive in first cost and maintenance and promote corrosion of the girder webs and shelf angles. The steel cross girders at the centre of the turntable require a depth at least as great as a standard floor system, so the depth of pit need not be increased for the floor system.

The depth of pit for the shorter tables will probably never be sufficient to compel the use of short through tables, say, less than 75 ft. The advantage of using through tables for the greatest lengths is indicated by the pit for the Pennsylvania 100-ft. deck turntable, in which the depth from base of rail to top of catch basin is 11 ft. 2 in., while for the Norfolk and Western 100-ft. through turntable the depth is only 7 ft. 6 in. Where through girders are used they should not be placed less than 15 ft. between centres, as with a closer spacing the danger arises of men getting caught between an engine and the girder flanges.

Loading and Stresses for Design.—Loadings and unit stresses used in the design of turntables are found to be greatly diversified. Cooper's loadings are believed to be unsuitable for this purpose on account of their short wheel-bases.

Turntables should be so designed that the deflection of the ends will not cause both ends to drag while turning heavy engines, and it should not be necessary to place the rails on the table too high above the approach rails to accomplish this, as that will result in too great a drop of the ends when an engine reaches the end of a table. In general the rails on the table should not be more than ¾ in. above the approach rails and should come down level while engines are passing on or off. A deflection of ½ in. at each end, then, will leave ¼ in. clearance over the circle rail while turning. The unit stresses should be so chosen that the deflection of each end will be not greatly in excess of that amount.

Although a bridge designed for Cooper's loading will support, without any increase in stress over that used in the design, modern engines considerably heavier than the Cooper's loading, on account of the longer wheel-base distributing the load over a greater length of bridge, the same engine on a turntable will cause the stresses that affect the deflection of the ends to exceed very materially those used in design, for the reason that the longer wheel-base increases the negative bending moment on a turntable.

The tables should be designed for the heaviest actual engine that could use them. The unit stresses should be chosen low enough to keep the deflection down to a minimum, 10,000 lbs. per square inch for tension and compression and 6,000 lbs. per square inch for shear being reasonable values. With those stresses, it is not necessary to add for impact except at the ends, where live-load stresses in parts subject to pounding should be increased 100 per cent.

Construction of Pits.—Drainage of pits is always important, and becomes a larger problem with long tables and deep pits. The most satisfactory drainage is provided by catch basins and gravity drains, where the highest water in the outlet is lower than the bottom of the pit. Where this condition does not obtain, the problem of drainage can be simplified by use of through type of table, decreasing the depth of pit; use of shallow, non-tipping tables; waterproof pits, with sumps and pumping.

Little has been done to handle the situation by waterproof pits, sumps and pumping, and it appears that the extra expense and the neglect that may be expected, combined with the very deep pits for modern deck turntables, is so great as to indicate the desirability of through girders, provided direct gravity drainage can be secured for the through pits. A careful comparison of expense should be made before the through table is adopted.

The old practice of flooring over the entire pit has almost disappeared. Standard bridge ties are now used on the stringers of through tables or on top of deck tables, with occasional ties long enough to support footwalks outside of the locomotives. The width of the floor is 14 to 16 ft., and sometimes foot railings are provided. In a few cases pipe handrails are used on each side.

Great care is necessary in constructing the centre foundation. Most roads use bases 12 ft. square on 16 piles, rock or pile foundations usually being required. The top or bottom of the concrete centre is reinforced in many cases, and sometimes both. Settlement of centres is often stopped by excavating a trench around the footing, extending down 2 or 3 ft. deeper than the footing to permit underpinning, and increasing the base by filling the trench with concrete, sometimes on piles.

Operating Details.—The committee finds no necessity for locks where tractors are used, the power brakes being considered sufficient. In all cases where tables are turned by hand, locks should be provided. The simple I-shaped forging, sliding between the webs, answers the purpose well. Although it is convenient to have such a lock connected so that it will slide by the manipulation of a hand lever, it can be satisfactorily operated by hand, rings being attached for ease of handling. At outlying points it might be advisable to provide a locking attachment to keep boys from playing with the table and getting injured.

Electric power has the preference on practically all roads, and turning by air motors next for outlying points where tables are not much used and where current cannot be obtained, and where trouble, necessitating turning the table by hand, will not be serious. Gasoline engines are recommended where electric current cannot be obtained and where liability of freezing renders the use of air motors objectionable.

Turntables of the non-tipping type, having supports at other points in addition to the centre, were considered by the committee, but it was found that they have given much difficulty to the principal users.

Approach and Circle-Rail Supports.—The committee recommends providing a support for the ends of the approach rails on creosoted coping timbers, not less than 12 in. wide at the narrowest point, and preferably 8 in. thick, with two heavy standard tie plates under the end of each rail, where the space permits this, or a special plate not less than 1 in. thick, 12 in. wide and long enough to pass under the two near rails of adjacent tracks, the plates to be drilled for track spikes or screw spikes and for lag screws for attaching them to the coping timber. The coping timber should be attached to the concrete by anchor bolts. Supports should also be provided for the circle rail by short creosoted ties about 15 in. centre to centre under main tracks and 24 in. elsewhere, with tie plates and screw spikes where available. To hold these ties in position and to prevent the accumulation of dirt and cinders, the space between them and between their outer ends and the parapet wall should be filled with concrete sloped to drain under the circle rail to the pit.

It is customary at present to build the circle walls of concrete, except at such points as timber walls are used to effect economy or for temporary installations. Where timber walls are used over hardpan or rock, blocking can be used, but care must be taken to break joints and in drifting the timber together to keep the wall from crowding forward. Where the foundation is not firm enough, piles should be driven as long as possible to refusal, spaced about 3 to 4 ft. centre to centre. Timber walls have been built, and can be built, in such a manner that they will be entirely satisfactory.

Where a concrete circle wall is used, great care must be taken to secure a sound foundation for the wall and for the circle rail in order to avoid settlement. The footing should be extended to hardpan or rock or supported on piles driven to refusal. The piles should be placed directly under the parapet and circle rail. Great care must be taken in placing the bearings of the approach rails and in placing the circle rail to get a perfect level. Some roads make the cross-section of the circle wall equal to that of a gravity abutment, but this is not necessary if a complete circle be constructed, as the arch effect permits the use of a considerably lighter wall.

It is of great convenience to have a recess in the parapet wall at some point and a concrete pit constructed around the recess through which access may be gained to the end of the table.

Practically all railroads report the use of concrete or brick paving for pits in standard installations at the most important points, concrete having the preference, but the majority also report many pits with no paving, the floor of the pit being finished with earth, cinders or gravel. Concrete or brick paving gives a much better appearing pit, but there is a question whether the expense is justified. The cost will be close to $1,000. A layer of cinders or gravel 6 to 12 in. thick will absorb all water and oil and will prevent the occurrence of mud. The growth of vegetation should be very easy to stop.

Conical Roller and Disc Centres.—The difference in cost between a poor centre and the best centre is so slight compared to the importance of avoiding trouble that the best centres available should be used. The conical roller centres appear to be satisfactory if properly designed, constructed and maintained. Improper attention to these features has caused much trouble and much criticism of this type. One of the principal faults with the design of former conial roller centres was the small length of the rollers, which created unit pressures greater than they should have been. This resulted in the wearing and flattening of the rollers and in the wearing of the rollers into the surfaces of top and bottom castings, requiring renewal of the entire centre. Rollers have now been lengthened and track plates provided on the castings, so that only the plates require renewal. The rollers and plates should be of hardened steel and the castings of steel.

In the earlier designs no means was provided for keeping the rollers a constant distance from the centre. Their working in resulted in rubbing on one another with consequent increase in difficulty of turning. Their crowding out resulted in the castings coming together and in the outer ends of the rollers working against the rough inner surface of the castings with damage to rollers and castings and increase in difficulty of turning. In later designs means are provided for holding the rollers in line. The most approved practice consists in placing a steel ring around the rollers, set screws or lugs projecting from the end of each roller or bolts passing entirely through the length of the rollers and through the live ring. Phosphor bronze frictionless washers or ball bearings are provided in many designs between the ends of the rollers and the live ring.

A large majority of the roads favor conical centres for turntables, though several report very successful results with disc centres. The committee recommends that properly designed disc centres be given serious consideration.

In the preparation of standard layouts the committee recommends the avoidance of frogs in approach tracks as far as practicable.

Relative to maintenance of turntables, it is believed that proper design and construction, together with frequent inspection, will simplify the work. They should be frequently cleaned and painted, with patch painting when necessary. At least once each year and as much oftener as centres are submerged by floods or turn hard for any reason, the table should be jacked up and the centre thoroughly cleaned and refilled with oil. To facilitate jacking, many roads provide steel brackets riveted to the table and concrete foundations for the support of the jacks on one diameter of the pit.

SOUTH AFRICAN WATER POWER

The Cape Times weekly edition of September 18th states that Mr. Charles Weidner, of Oudtshoorn, Cape Colony, has formed a strong syndicate which has acquired 100,000 acres of land with a frontage of some thirty miles on the Orange River, upon which it is proposed to erect power stations to generate electric energy from the volume of water falling over many cataracts.

This hydro-electric power is to be utilized in various ways:—

(1) To drive powerful pumps by which water may be raised to higher levels, in order that wide areas may be irrigated.

(2) To operate flour mills and other manufacturing plants which are to be established by the syndicate.

It is hoped that Canadian manufacturers may be interested in the above; and the subject is also interesting to persons engaged in irrigation work, as showing what is being done in South Africa.

ELECTRICAL SUPPLY OF MONTREAL.

Considerable interest has been aroused here in power and financial circles, and among the citizens generally, in the report which has come from Quebec to the effect that the National Hydro-Electric Company, with head offices at Montreal, is making application at the present session of the Quebec Legislature for the necessary powers to enable it to make use of the streets and roads of Montreal and, in fact, of the streets and highways generally in about a score of counties of this province.

The National Hydro-Electric is the company which owns the Carillon Falls power, of which considerable has been heard from time to time during the past few years. The Falls are situated some thirty-five miles up the Ottawa River from the city of Montreal, and they mark the head of navigation so far as the larger steamers are concerned. From Montreal to Carillon and return is the round trip of the line of steamers of which Mr. R. W. Shepherd, who died last week, was the manager.

The statement was made that the falls are capable of producing 160,000 horse-power, and that it would cost $10,000 to develop them. Manifestly, one or two cyphers must have been dropped off the sum mentioned, inasmuch as $10,000 would not commence to develop a power of any consequence, and the company would not be applying for powers to issue $12,000,000 bonds, as it is doing, if it could get along with just $10,000.

So far as concerns the report that 160,000 horse-power can be developed at the Falls, this would seem to be confirmed by the report of the Conservation Commission, it being therein stated that the Falls have a total possible capacity of 200,000 horse-power, when the Georgian Bay Canal has been completed. By this is no doubt meant that the storage reservoirs planned for the watershed near French River must be also brought into play before the total of 200,000 horse-power will be available. The head of water for the complete development would be about 40 feet.

Under present conditions, the conservation report gives Carillon Falls a possible development of 26,000 horse-power, at a head of 13.5 feet. Whether, by the expenditure of considerable money, any more than this can be developed previous to the actual completion of the canal or not, is not stated.

Mr. Henry Miles, the president of the company, is a well-known man in Montreal, having a few years ago been president of the Montreal Board of Trade. He says:—

"We believe that Montreal wants more power, and we want the privilege of bringing it in. The small plant we already have will shortly be in operation, and it will supply the neighboring municipalities with their requirements, as well as the company with what it requires while carrying out the work on the larger installation. Montreal wants more electric power, and if they give us the opportunity we will supply it."

Montreal should certainly be well supplied with electrical power very shortly. Already several companies are sending in current from different hydraulic developments, great and small, within one hundred miles of the city. The Montreal Light, Heat and Power Company is supplying from its developments at Chambly, Lachine Rapids and Soulanges Canal somewhere around 30,000 to 35,000 horse-power, and in addition to this it has auxiliary steam plants within the city. The principal interests in the company, as well as in its old partner, the Shawinigan Water and Power Company, have lately acquired the Cedar Rapids power. This is situated near the Soulanges development just referred to, and is probably the largest power obtainable anywhere near [illegible]. It is claimed that in a very few years the Cedar Rapids Manufacturing and Power Company will be sending in 150,000 horse-power to the city of Montreal, or to the surrounding district. It seems likely, however, that a very considerable portion of this will be taken by certain large special industries which it is claimed will be established here by the time the power is ready. The Montreal Light, Heat and Power Company is also bringing in a large amount of power from Shawinigan Falls, it having contracted to deliver all the power for the Shawinigan Company required on the Island of Montreal. The present contract is for about 63,000 horse-power, though it is said that not all this is being asked for as yet. The Shawinigan Company is able to develop about 175,000 horse-power. Of this, 45,000 is sold at the Falls as hydraulic power, while the installation is prepared to deliver 85,000 horse-power, and the development is completed for 45,000 more, although the electrical machinery has not been installed for it. All the power previously mentioned, including 63,000 of the Shawinigan Company, is virtually in the hands of the Montreal Light, Heat and Power Company, and it is generally the ambition of each new power concern to compel the "monopoly" to buy it out.

The Canadian Light and Power Company is the one concern which is in opposition, and is likely to remain in opposition. Just what its development is, is difficult to say. It has been variously estimated from 7,000 horse-power to 25,000 horse-power. The statement is made on excellent authority that the company is actually disposing of and receiving pay for over 13,000 horse-power, so that ought to dispose of the 7,000 estimate. On the same authority it is stated that the company has a connected load of upwards of 20,000 horse-power. This does not include what is being generated in the city and district of Montreal, by the company's own plants or by those of its subsidiary companies. The Saraguay Electric and Water Company, which is a subsidiary of the Canadian Light and Power Company, is applying at the present session of the Quebec Legislature for authority to change its name to the Montreal Public Service Corporation, and to increase its capital to $5,000,000, and to extend its borrowing powers. All these companies, together with the Montreal Tramways Company, are subsidiaries of or component parts of the Montreal Tramways and Power Company which operates the street railway system of the city and island.

From the above it would seem that the power companies of Montreal are in a position to supply at all times from 100,000 to 125,000 horse-power. Should there be occasion, the Shawinigan Water and Power Company can provide 45,000 more, and it is understood that the Canadian Light and Power Company is making an effort to increase its capacity. The capacity of the Cedar Rapids Manufacturing and Power Company, within thirty miles of the city, may be counted on, and if the National Hydro-Electric, with its Carillon Power be added, it would seem that the requirements of the city of Montreal may double without pressing unduly upon the producing capacities of the companies mentioned.

◆

The C.P.R. bridge across the Saskatchewan River at Outlook has been completed. The last girder was put into place recently and immediately the work of laying the rails was commenced. This bridge is one of the biggest in Western Canada, being over three thousand feet in length, and 156 feet in height. The construction work was commenced in 1909, and is conceded to be one of the biggest undertakings ever attempted to cross the Saskatchewan River. There are nine piers of solid concrete and the piers are 110 feet above the water level with a steel superstructure 46 feet high.

IMPROVEMENT IN FIRE HYDRANTS.

Every city engineer and fire chief is well acquainted with the cost of fire hydrants, and would welcome any efficient method that would allow of economy and certainty in this matter, but the question does not lend itself to an easy solution, owing to the increased pressure that is constantly being demanded from these hydrants by firemen in their improved methods of fire-fighting.

It has long been the ideal of fire fighters to secure some appliance that would automatically regulate the pressure of the stream, and several valves for this purpose have been devised, but their cost was prohibitive to their application to every hydrant. The problem has been solved by the portable hydrant head illustrated by Fig. 1.

This portable hydrant head may be quickly attached to any existing hydrant opening and contains a number of hose taps, each furnished with an automatic valve. In a city where the system is operative each hose wagon carries one hydrant head, and the connection with the main is made immediately upon arrival.

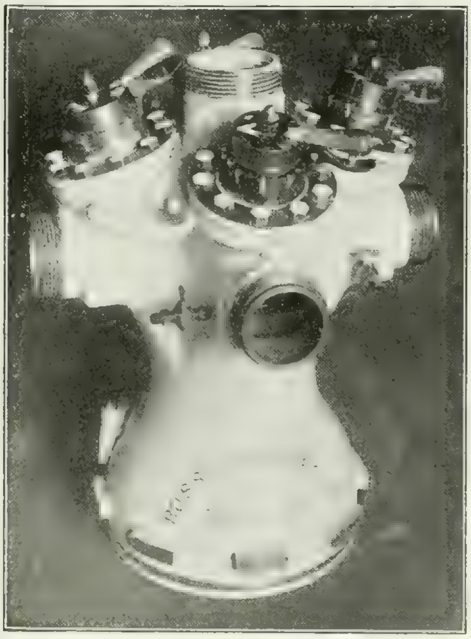

Fig. 1.—View of Portable Fire Hydrant Head.

This system was recently introduced in the high-pressure area of Baltimore, the hydrants being constructed for that municipality by the Ross Valve Manufacturing Company, of Troy, N.Y.

When attached to the main each hydrant sets flush with the pavement, and in order that many points of contact will be at the option of the firemen the means of connection with the water supply is greatly simplified; consisting of a cutting in the main with a section of 8-inch pipe welded in. The hydrant itself is of semi-cast steel resting on a concrete base in a concrete chamber with the upper end constructed to receive the portable head which is secured by a slight turn and may be placed firmly in position in a few seconds. When the special head is removed a grating covers the hydrant top and tap, giving a neat and unobstructive finish. The portable head has five hose taps and weighs about 110 pounds; four of the taps are fitted to take 2½-inch hose couplings and the fifth is fitted for a 3-inch hose. The tap handles are so placed and weighted that they balance the entire structure.

RAILROAD NOTES.

Work has been suspended on the Providence extension of the Central Vermont. The work has been stopped, it is said, owing to the unsettled condition of the money market in England. It was the first intention of the company to have the road from Palmer, on the Central Vermont, to Providence, a distance of 57 miles, completed by the end of the year. It is stated that thirty per cent. of the grading has been accomplished.

The Canadian Northern Railway will probably seek legislation this season providing for its maritime outlet for through traffic from the West. The final eastern link of the Canadian Northern system from Sudbury to Quebec now under construction, will be completed within a year or so. There is no provision for further outlet to the seaboard, and the road wants to be in a position to secure the through haul, instead of having to turn its traffic over to the rival roads at Montreal or Quebec when the St. Lawrence navigation season closes. The alternative schemes are running rights over the Intercolonial, or connections with the Boston and Maine.

The company is applying for legislation authorizing the construction of a line from Montreal to Levis, with a branch running down from St. Hyacinthe to Sherbrooke. At this latter point the road will make connections with the Boston and Maine line, giving a through outlet for export grain and other commodities via Boston. Thus the Canadian Northern Railway would be in a good position to compete with the Canadian Pacific Railway and the Grand Trunk Railway from coast to coast, and would be independent of these roads or their allies for the Atlantic outlet.

Important changes are to take place in the agreement between the Grand Trunk Railway system and the Wabash Railway, in connection with the Air Line branch, over which the Wabash has running rights. President Chamberlin, of the Grand Trunk, and General Manager Deland, of the Wabash, recently made an inspection of the Air Line division, so that there is indication that the Wabash Railway will increase its interests in Canada.

The Wabash Railway has completed arrangements for the purchase of three of the old Michigan Central car ferries for use on the Detroit River. Heretofore, the Wabash has used the Grand Trunk car ferries to handle its trains across the river.

Twenty miles of steel of the Temiskaming and Northern Ontario Railway on the new Elk Lake branch have been laid, leaving about ten miles to be completed. While a service may be inaugurated by Christmas, the Montreal River has yet to be crossed. The piers and coffer-dams are all ready, and the steel work is now being assembled at the factory. With fair conditions the work ought to be completed late in December.

The Chatham, Wallaceburg and Lake Erie Railway has been bonded by the Canadian Northern interests. The sum of $25,000 has been paid to secure the option. The action of the Mackenzie and Mann interests in securing this line is regarded as further evidence that the Canadian Northern Railway means to push through with the work in Western Ontario to Windsor.

◆

The Peace River and Great Western Railway Company has opened offices in Edmonton and construction will be pushed next season. In the meantime preliminary work will be done. It is stated that surveys will be completed, ties cut along the right-of-way, and supplies sent forward during the winter for construction camps to be established in the spring.

LOSS OF HEAT FROM STEAM PIPES.

A paper was read by Prof. Petavel and Dr. C. N. Lander before the Engineering Section of the British Association (Dundee, September, 1912), in which they gave results of an experimental investigation to determine the relative importance of convection, conduction and radiation in promoting the loss of heat from hot wires and from hot pipes. They found that a bare 1-in. steam pipe in free air lost heat at the rate of 3 B.T.U. per sq. ft. per hour per deg. F. of temperature difference. Of this total, 15 per cent. was due to radiation, 4 per cent. to conduction, and the remaining 81 per cent. wholly to convection. In insulating a pipe it is necessary to determine the best density of the packing material. The best of such materials have thirty times the conductivity of air, so that, were it not for convection, clothing a pipe would increase the loss of heat. What actually happens is, that covering a pipe greatly diminishes the convection, but by an amount which depends on the closeness of the packing. If too tightly packed, the efficiency will be low, owing to an increase in the conductivity; while if too loosely packed, a large proportion of the convection still continues. Hence there is in each case a certain best density for the packing. In the case of slag wool, this is one-fourteenth of the actual density of the individual fibres. In this case the loss by conduction will rise from 0.1 to 0.4 B.T.U. per sq. ft. per deg. F. per hour, but the loss by convection will fall from 3.2 B.T.U. to 0.1 B.T.U. per sq. ft. per hour, the net loss being one-seventh of what it will be with a bare pipe.

With bare metal pipes the character of the surface has a distinct influence, but it affects only the loss by radiation. With a good machined surface this loss is reduced from 15 per cent. of the total to about 7 per cent.; polishing the pipe to a mirror-like surface will reduce this loss still further to between 3 and 4 per cent. of the total. Little, however, is to be gained by polishing in the case of ordinary steam-pipe temperatures, as the main loss—by convection—is not affected in any way by the condition of the surface. When the pipe radius is small, the conduction loss becomes the more important, so that the total loss varies with the pipe diameter. For pipes larger than ½ in. in diameter, however, this increased loss by conduction is unimportant. For bare pipes of about 1 in. in diameter the total loss, as stated above, is about 3 B.T.U. per sq. ft. per deg. F. per hour; for pipes above 4 in. in diameter the loss becomes nearly constant at 2 B.T.U. per sq. ft. per deg. F. per hour, irrespective of diameter.

◆

RELATION OF RAILWAYS TO DEVELOPMENT

President Finley, of the Southern Railway, in an address before the Transportation Club, of Indianapolis, spoke on "The railway and the shipper." He said in part: "The railway and the shipper are each dependent upon the other. It is recognition of this dependence upon the shipper that has led the railways of the United States to adopt policies having for their purpose the enlargement of the business of shippers on their lines and the multiplication of the number of shippers. These helpful policies are based on sound business principles, for if we look beyond the immediate present, it is apparent that the ultimate prosperity of the railway is dependent upon the lasting prosperity of those upon whom it must rely for its traffic.

"In my opinion it is equally true that the shipper is dependent for his ultimate prosperity upon the lasting prosperity of the railway."

Mr. Finley pointed out that not only wages, but materials and supplies used by railways have advanced in price, and that their taxes, levied by government, have increased $80,000,000, or 167 per cent., since 1900, and amount for the fiscal year 1912 to about $130,000,000.

These facts were presented in order that some conception of the railway situation of to-day and of the problems with which railway managers must contend in their efforts to provide facilities for serving the shipper might be formed. Looking to the future development of the country and the growth of agriculture and manufacturing, it is clear that an increase in carrying capacity will be needed. Leaving out of account the new construction that should be undertaken in some localities, generally speaking, the policy of the railways should be that of keeping their existing plants abreast of requirements.

The practical question confronting those responsible for making these improvements is that of providing the necessary capital. The ability of the companies to attract the investment of new capital on reasonable terms will be measured by their net earnings capacity. Railway credit is dependent upon net income, and it is essential to the continued development of the American railway system that units of revenue shall bear a proper economic relation to units of cost.

The shipper who takes this broad view of the railway situation in all of its far-reaching economic bearings will be led to the conclusion that some rate reductions that are asked for are unreasonable and hurtful to the best interests of all concerned, and that some rate advances proposed by the railways would be helpful in their ultimate effects to the railways and the shippers alike.

When the time shall arrive that the shipper shall take the same lively interest in the railway by which he is served —when he shall study its reports and understand its needs and its resources, and when he shall look upon its progress as an indispensable factor in his own prosperity, the solution of the railway problem of the United States will be arrived at and the interests of the railway and the shipper have been promoted.

This is an opportune time for the railways and the shipper to draw closer together in mutually helpful cooperation. We have entered upon a period of general prosperity which is reaching all classes of our people, and it has come to stay.

◆

ELECTRIC SMELTING IN CANADA

That a report demonstrating that electric smelting of Canadian ores is now a commercial possibility will be issued early in the year by the Mines Branch of the Department of Mines is announced in conservation. It will cover the results obtained from the use of the 100-ton electric furnace that was installed at Sault Ste. Marie, in 1906, for experimental purposes. In addition, the perfecting of the process as carried out in Sweden will be dealt with.

Such an announcement is of great importance to Canada, and especially to Ontario. Hitherto, the extensive iron deposits in Ontario have been scarcely touched, for two reasons: First, Ontario has to import all its coal; second, Ontario iron ores contain a relatively high percentage of sulphur, which could not be removed by the blast furnace. The new process will eliminate both these objections. Electricity will not only smelt the ore, but, by means of the greater heat that it will provide, it will volatilize and drive off practically every particle of the sulphur. The country surrounding the important iron deposits possesses valuable water-power resources, which, for the most part, have not yet been developed. It is thus easily seen that the introduction of an economical electric smelter will make possible an industry of vast importance to Canada.

COAST TO COAST.

St. Lawrence River.—The Minister of Marine and Fisheries, has ordered a strict enquiry into the recent shipwrecks that have occurred in this river.

Saskatoon, Sask.—The announced opening of the street railway for December 1st will likely be delayed owing to the non-arrival of the power house generators.

Ottawa, Ont.—The Board of Railway Commissioners for Canada will hold a sitting on Saturday, December 3rd, to discuss the protection of car repairers.

Ottawa, Ont.—Plans for the new Welland Canal are nearing completion, and from the estimates now available, it is expected that this work will cost $50,000,000 and take five years in building.

Calgary, Alta.—A recommendation made to the city council in a report submitted by the joint committee of council, park board, school board, and city planning commission, calls for a $600,000 system of parks, boulevards and playgrounds.

Province of Alberta.—At a meeting of municipal representatives recently held in Regina, the system of bonusing industries was condemned and a resolution introduced to have the governments of the other western provinces pass a law in conjunction with the authorities of this province, to have this evil reduced.

London, Ont.—Ald. Ashplant has made an estimate of expenditures upon the West London Embankment since the year 1898. During this space of time the sum of $31,000 has been spent on this work to keep the breakwater in proper condition. He will introduce a motion before the council to spend $45,000 and make the affair permanent.

Stratford, Ont.—Some items extracted from the Board of Trade report are of interest. The capital invested in local factories is reported as $3,597,913, with an annual output of $5,807,148. A wage bill of $1,323,199, and an army of 2,337 male and 553 female employees, with a total assessment of $9,708,780. The city has 12.81 miles of paved and macadam roadways, and 38.74 miles of concrete sidewalk.

Hamilton, Ont.—In January the ratepayers will vote on the new hydro-electric commissioners, and also vote on by-laws which, if carried, will authorize an expenditure of $910,000 for various civic works. The principal by-law will be to provide for the building of a storm sewer at a cost of half a million. Another is to raise $130,000 for the purpose of purchasing mountain face properties for park purposes.

Province of Saskatchewan.—The amount of construction of telephone lines in this province accomplished since March 1, 1912, is approximately 800 pole miles, and 1,572 wire miles. This gives a total for the province of 2,964.07 pole miles, and 9,744.3 wire miles. The number of toll offices opened and purchased to date is 228, and the total number of exchanges built and purchased to date is 80, with 12,802 subscribers.

Ottawa, Ont.—A report demonstrating that the electric smelting of Canadian ores is now a commercial possibility will be issued shortly by the mines branch of the Department of Mines. It will cover the results obtained from the use of the 100-ton electric furnace which was installed at Sault Ste. Marie in 1906 for experimental purposes and will also deal with the perfecting of the process as carried out in Sweden.

British Columbia.—The annual report of the Minister of Mines of British Columbia shows that taking the province as a whole there were 546 tons of ore mined per year for each man employed about the mines. In this respect, however, the districts vary materially as follows: Slocan District, 113 tons; Nelson District, 130 tons; Trail District, 372 tons; and in the Boundary District 1,201 tons were mined per man employed.

Victoria, B.C.—Creditors of the defunct Midway & Vernon Railway, a considerable part of which undertaking was taken over at the chartering of the Kettle River Valley Railway by that company, are to receive in the near future full settlement of their legitimate claims for labor, material, teaming, etc. Upon the incorporation of the Kettle River Valley line with government assistance in its financing, such aid was made conditional upon the payment of outstanding claims as against that portion of the line which they will utilize.

Dauphin, Man.—At the Board of Trade meeting held last week it was decided to approach the city council to further investigate the water power scheme at Meadow Portage with a view to approaching the government to connect the two lakes by a canal and secure the right to install and operate hydro-electric power plant. There being a fall of 18 feet between Lake Winnipegosis and Lake Manitoba, it is anticipated 40,000 h.p. can be generated there at little cost. This would give Dauphin a fine power supply at comparatively small cost.

Galt, Ont.—Ald. Dakin, chairman of the local Hydro-Electric Commission, will apply for power to inaugurate underground wiring, thus compelling the Bell Telephone Co. and C.P.R. and G.N.W. telegraph companies to transfer transmission lines to conduits. The policy to be followed is that conduits shall all be laid by the corporation, primarily for hydro-electric wires, but the extra cost to accommodate the lines of private companies shall be paid by them, according to the space used. This places the construction of the conduits entirely in the hands of the municipality.

Hamilton, Ont.—The matter of placing all wires in the down-town section of this city, as mentioned in *The Canadian Engineer* of last week, has been settled by the Hydro-Electric Power Commission issuing an order for the placing of all wires in the down-town district underground. This order involves the Cataract Power Company, the Hamilton Hydro-Electric service, and states that provision shall also be made for the telephone and telegraph wires. This is the first order of the kind to be issued under the legislation of last session under which the Hydro-Electric Commission could hold joint sittings with the Dominion Railway Board.

Province of British Columbia.—As the lines of the Grand Trunk Pacific Railway are pushed farther and farther westward several croppings of coal are found in unexplored portions of the province. Among the best so far found is the property on Kitseukla Creek, 12 miles from the railway and nearly south of Hazelton on the Bulkley River. Advices from British Columbia state that there are 31 seams of coal outcropping on this land and that of these two have been partially developed, one of them being 7 feet in thickness and the other 4 feet. The coal, according to recent assays, yields 68.5 per cent. of coke in addition to being a high-grade steaming and domestic fuel.

Collingwood, Ont.—The energy consumed by ratepayers from the civic power plant shows a steady increase. The monthly totals for last year and this are shown:

	1912	1911.
January	$2,069	$1,011
February	1,848	1,759
March	1,391	1,392
April	1,270	1,518
May	1,118	1,126
June	1,011	910
July	974	991
August	839	663
September	1,066	905
October	1,561	1,250

London, Ont.—Adam Beck, chairman of the Ontario Hydro-Electric Commission, has submitted a report to the council of London, Ont., recommending the electrification of the municipally owned London and Port Stanley Railway at an approximate cost of $890,000. The report recommends the adoption of the overhead system and the double-tracking of the entire line between London and Lake Erie. The intention is to maintain a high-speed half-hourly service between London and St. Thomas. A fifteen-minute shuttle service between St. Thomas and Port Stanley would also be maintained for especially heavy traffic. The estimated gross revenue for the first year under electric operation is $261,500. Of this $140,000 would come from freight and $121,500 from passenger traffic. The estimated disbursements are $220,545, consisting of $130,000 for operating expenses and $90,545 on capital expenditure, leaving net earnings of about $41,000.

Edmonton, Alta.—Further extension of municipal ownership at Edmonton, Alta., was indicated when the commissioners directed City Engineer Latornell to report upon the cost of installing a paving plant of not less than 100,000 square yards capacity during the building season, also to engage a construction engineer qualified to take charge of of the city's paving work. The plant is to be in operation early next spring. The cost is estimated at between $40,000 and $50,000. The office of construction engineer is a new one in the city's service. His duty will be to take charge of the plant and supervise the paving work. The city will compete with private firms in all municipal work, taking contracts to keep the plant running at full capacity throughout the season. Five hundred thousand square yards of new pavement will be laid by the city next year, as against about 250,000 square yards put down during the season of 1912. It is expected that the specifications will be announced in January or February, giving ample time for contractors to assemble men and materials.

Niagara Falls, Ont.—The Ontario Power Company has filed an application with the Queen Victoria Park Commissioners for permission to install another turbine and generating unit, to be known as wheel No. 13. The necessity of installing this additional unit is the natural result of the greatly increasing load of the hydro-electric, which has assumed such large proportions that it has been found next to impossible to supply the demand for electric energy with the present machinery. The last two units installed, Nos. 11 and 12, have not yet been completed, but probably will be put in operation on or about January 15, but unit No. 13 will probably be placed in commission by July 1. With ten units already in operation, approximately 125,000 electrical horsepower is being generated, and this will be greatly increased with the completion of the three additional units. All of the exterior excavation work on the new wheel and Nos. 11 and 12 will be entirely completed by April 15, in compliance with an agreement between the power company and the park commission.

Province of Saskatchewan.—The large amount of work which has devolved upon the Department of Public Works in connection with the laying out of the grounds of the numerous government buildings in the province has necessitated the employment of an expert in this line, and Mr. Malcolm Ross has been appointed to take charge of this very important work. The grounds of the parliament buildings, of the university, the normal schools, the provincial asylum and the court houses will all be under his care. In some of the larger works such as the university and parliament buildings grounds where the architectural features of the buildings will have to be considered, Professor Mawson has been retained to assist Mr. Ross. Mr. Ross, who was until recently Parks Superintendent of the City of Regina, is a man with high qualifications for his new position. He is a Bachelor in Scientific Agriculture, a graduate of Guelph Agricultural College, with a post graduate experience in the several parts of the United States, and was in the employ of Mr. George Vanderbilt on the Viltmore estate in North Carolina.

Edmonton, Alta.—One hundred thousand dollars is the estimated cost of a three-story market building to be erected by the municipality of Edmonton, Alta., early in 1913. The plans, prepared by City Architect Jeffers, show a structure of horseshoe shape, built of reinforced concrete and brick with stone trimmings. The site chosen for the building is the present hay market in First Street, which is served by the municipal street railway and is within easy distance of the Grand Trunk Pacific, the Canadian Northern and the Edmonton, Dunvegan & British Columbia Railroads. The last named line is under construction and will serve the north country. Provisions have been made for stores and offices in the wings of the building, which will face First Street and Queens Avenue. An arcade entrance will lead to the market proper, consisting of long rows of stalls, where market gardeners and growers will be able to display their products and deal directly with the consumer. It is probable that a refrigerating system will be installed in the butter and egg and fowl and meat departments. The building to be erected next spring will form part of the general market. It is expected that a by-law to provide funds will be submitted to the ratepayers in a short time. Commissioner Chalmers, who has charge of the plan, states that the market is to be the central point for the street railway system, as well as for all the suburban lines on the north side of the Saskatchewan River. The suburban roads will become express lines within the city limits, running direct to the central station. This will facilitate the handling of products from the suburban communities and will be the means of settling the close-in districts.

◆

EXPERIMENTS ON REDUCTION OF STRESS.

A description of and data from experiments made at the testing laboratory of the Darmstadt Technical High School on the reduction of stresses in metal members by rounding off sharp angles are given in a recent issue of the Journal of the American Society of Mechanical Engineers. The author states that although the fact that the stresses are particularly large at sharp angles was known for a long time, there are practically no experiments available showing numerically the precise influence of the radius of curvature on the stress at and near the point of flexure. Fig. 1 shows graphically how the change in the radius of curvature affects the distribution of lines of equal stresses. Among other things, these experiments have established the fact that the neutral point of stresses as found from actual measurements does not coincide with that determined theoretically.

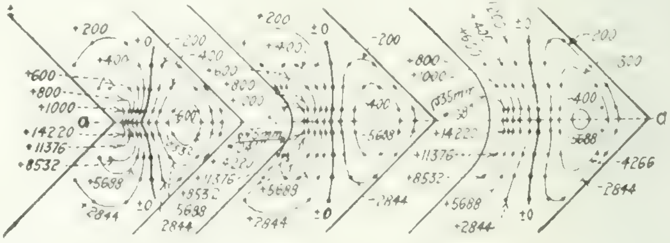

Fig. 1.—Distribution of Lines of Equal Stresses for Various Radii of Curvature.

PERSONAL.

W. COLIN EWING has been appointed junior assistant to Mr. F. G. Goodspeed, district engineer of St. John, N.B.

R. H. FLAHERTY, of Port Arthur, Ont., has returned from an exploration of Ungava district, in the interest of Mackenzie and Mann.

A. E. ROSEVEAR, assistant general freight agent of the Grand Trunk at Montreal, has been appointed assistant to vice-president, with office at Montreal.

HON. LOUIS CODERRE, M.P. for Hochelaga, Que., has become Secretary of State and head of the Department of Mines, which has been transferred from the Minister of the Interior to the Secretary of State.

R. S. LEA, the well-known consulitng engineer, of Montreal, is on a five-week Western trip. He will visit Medicine Hat, Edmonton, Kamloops and Vancouver, in all of which cities he has been retained in connection with large engineering undertakings.

Mr. E. L. Cousins, B.A.Sc.

EDWARD L. COUSINS, B.A.Sc., engineer to the Toronto Harbor Commission, is a graduate in civil engineering of the University of Toronto. The Harbor Commission, who were appointed last fall, chose him as their engineer in January of this year. Mr. Cousins was appointed divisional engineer for the Grand Trunk Railway, with headquarters in Toronto, on graduation. In July, 1910, he became Assistant City Engineer in charge of railways, bridges and docks. He was born in Toronto, and received his early education at St. Andrew's College. The plans of the Toronto harbor improvement, which appear in this issue, were prepared under his direction.

DR. FRANK D. ADAMS, dean of the Faculty of Engineering, McGill University, was recently the guest of honor at a dinner given at Albany, N.Y., by Dr. John M. Clarke, the state geologist, to celebrate the dedication of the new State Survey and Museum Building.

DAVID WHITE has been appointed by the secretary of the interior as chief geologist of the United States geological survey to succeed Waldemar Lindgren, who leaves Washington to become Rogers' professor of geology and head of the geological department of the Massachusetts Institute of Technology.

FRED. A. ROBERTSON ('08 Science, University of Toronto) who has been in charge at the Toronto office of the cement and reinforced concrete departments of the Canadian Inspection and Testing Laboratories Company, Limited, has severed his connections with the above concern to join the selling forces of the Canada Cement Company, Limited, out of Toronto.

ROC MAC CONSTRUCTION.

During 1911 a 1,200-ft. section of Yonge Street, at Toronto, Ont., was reconstructed for 30 ft. of its width with broken stone and the preparation "Roc Mac." The method of construction, as described in the last annual report of the city engineer, was as follows: The surface of the old macadam was first swept thoroughly in order to remove as much of the mud as possible. Upon this prepared base a paste consisting of a mixture of limestone dust and Roc Mac solution was then spread to a depth of about 1½ or 2 ins. The proportions of this mixture were ⅓ cu. yd. of dust to 5 gals. of the solution. Granite crushed to about a 2-in. size was then evenly spread to a depth of from 3 to 4 ins. The pavement was then rolled until the paste worked through the stone from the bottom and formed a slurry on top. All surplus slurry was always swept forward to the head of the work. This character of work depends for its existence largely on the care with which the rolling is done, it being necessary to carry on the rolling constantly until all voids are absolutely filled. Yonge Street carries perhaps a larger volume of traffic entering and leaving the city than any of the other main entrances, and during the progress of the work described above, this traffic was not interrupted for a moment, all vehicles being allowed to drive over the work no matter what stage it was in. It was found that the roadway when completed, although roughly used, had a very hard, compact surface, and for the few months subsequent to its completion it has carried all traffic without receiving any apparent impression other than that shown in the thin film of mud covering it in wet weather. The cost of the work was about 78 cents per square yard.

THE NOBEL PRIZE.

The Nobel Prize for physics has been awarded Gustaf Dalen, a Swiss engineer, who is head of the Stockholm Gas Company.

The Nobel Prize for chemistry has been divided between Prof. Grignard, of Nancy University, and Prof. Paul Sabatier, of. Toulouse University.

The value of these prizes is $38,600 each

ELECTRICAL MEETING IN MONTREAL.

Mr. Fred Thompson gave an interesting paper before the Electrical Association recently on "Some Early Electrical Installations in Montreal." In 1883, he said, it was considered necessary to give an exhibition, and it fell to his duty to show some of the wonders of electricity in heating, cooking and lighting. The cooking demonstrations on electric stoves were, however, faked, and the tasty beefsteaks, fried eggs, tea and toast that were so praised were spirited from a back room, where they had been cooked on a gas stove, while those tried on an electric stove were badly frizzled.

The lighting of McGill University in 1884, when the British Association, headed by Lord Kelvin, visited the city, and how they had to run wires over citizen's front doors, trees and shutters, and how citizens were unable to open their doors, and threatened legal proceedings, was told in a most interesting manner by the speaker, who said that the ladies had taken a fancy to learn electricity, but their ardor cooled when they were put to covering wires, which was a very dirty job.

The establishment of connection between Montmorency Falls and Quebec, the running of wire across Victoria Bridge, and the railway experiments in 1892 were also referred to by the lecturer.

OBITUARY.

MR. PETER LYALL, well known in Canadian contracting circles, died at his home in Montreal recently. He was president of the Peter Lyall Construction Company, and connected with many other interests. Mr. Lyall was born in Caithness, Scotland, seventy-one years ago. He was early apprenticed as a stone mason and after thoroughly mastering his trade he came to Canada in 1870, beginning business under the auspices of his cousin, Peter Nicholson. Six years later he founded the contracting business which bears his name, and with which his three sons, William, Traill and Peter, Jr., are associated. This firm has developed until to-day it is unquestionably the largest construction company in the Dominion.

MR. GEORGE CRADDOCK, a well-known architect of London, Ont., died at his home in that city on November 16th last. He designed many of London's buildings.

COMING MEETINGS.

THE CANADIAN SOCIETY OF CIVIL ENGINEERS.—Meeting of the Electrical Section will be held in the rooms of the Society, 413 Dorchester St., West, Montreal, Nov. 21st at 8.15 p.m. Paper on "Transmission Line Design," by Mr. Julian C. Smith, M.C.S.E.E., will be read by the author. Chairman, L. A Herdt

THE CANADIAN INSTITUTE.—198 College Street, Toronto. Saturday Evening Lecture, Nov. 23rd, at 8 o'clock. "The Prevention of Sewage Pollution relative to Water Supply," by T. Aird Murray, C. E., Toronto. Secretary, J. Patterson.

NATIONAL ASSOCIATION OF CEMENT USERS.—December 12th to 18th. Annual Convention, Pittsburgh. Pa. President R. L. Humphrey, Harrison Building, Philadelphia, Pa.

AMERICAN CIVIC ASSOCIATION.—Annual Convention will be held at Baltimore, Md., November 19th to 22nd. Secretary, Richard B. Watrour, Union Trust Building, Washington, D.C.

UNION OF MANITOBA MUNICIPALITIES.—Programme for Ninth Annual Convention to be held in Convention Hall of the Industrial Bureau, Winnipeg. Nov. 26, 27, 28, 1912. Secretary, Reeve Cardale, Oak River, Man.

AMERICAN WOOD PRESERVERS' ASSOCIATION.—Ninth Annual Convention will be held at Chicago. Jan. 21-23, 1913. Secy-Treasurer, F. J. Angier, Mount Royal Station, B. & O. R. R., Baltimore, Md.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. Secretary, E. L. Power, 150 Nassau St,, New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE · Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving: Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh B. Fergusson, 911 Rogers Building, Vancouver, B.C. Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre: Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex Mayor of Westmount

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose Secretary Treasurer G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man. Secy Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor, Secretary-Treasurer Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President Dr. A. E. Barlow, Montreal; Secretary. H. Mortimer Lamb, Windsor Hotel Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr, G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5. Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only, unless otherwise noted, at the office of The Candaian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
12-10	—400,000 sq. yds. Asphalt and Bitulithic Pavement, Edmonton, Alta .... (P. & S.)	11-21

TENDERS.

Dunnville, Ont.—The time for receiving tenders for a turbine pump installation for domestic and fire purposes in the town of Dunnville, has been extended to Thursday, 28th November, 1912. Allan Mair Jackson, Superintendent of Water Commission. (See Advt. in The Canadian Engineer.)

Edmonton, Alta.—Tenders addressed to the City Commissioners, will be received until noon of November 25th, 1912, for the construction of the substructures of the 5th St. Bridge. Plans and specifications may be obtained at the office of the City Engineer, 623 2nd Street.

Edmonton, Alta.—Tenders for approximately 400,000 sq yds. of asphalt and bitulithic pavement, will be received at the office of the City Commissioners, Edmonton, until noon of December 10th, 1912. Plans, specifications, etc., may be obtained at the office of the City Engineer. Plans and specifications are also on file at the office of The Canadian Engineer, and the Contract Record, Toronto. A. J. Latornell, City Engineer. (See advt. in The Canadian Engineer).

Kamloops, B.C.—Tenders will be received until noon of December 5th, 1912, for 1,000-h.p. steam, pumping and electrical equipment of the new power station for the city of Kamloops. Plans and specifications may be seen at the office of J. J. Carment, City Clerk, and at the offices of DuCane, Dutcher & Co., Consulting Engineers, Vancouver, B.C., and R. S. Lea, New Birks Building, Montreal. (See advt. in The Canadian Engineer).

Montreal, P.Q.—The Central Railway Company of Canada invites tenders for supplying railway ties in lots of five to one hundred thousand, for delivery at a number of different points. Specifications, etc., at the office of F. Stuart Williamson, Chief Engineer, 44 Beaver Hall Hill, Montreal. Tenders will be received until noon of December 20th, 1912. (For full particulars see advertisement elsewhere in The Canadian Engineer.)

Moose Jaw, Sask.—Tenders will be received at the office of the City Commissioners, Moose Jaw, up to noon of December 6th, 1912, for construction and erection of a steel bridge of One Hundred forty-five foot span across Moose Jaw River at Moose Jaw. Plans and specifications on file at the office of the City Engineer. (See advt. in The Canadian Engineer.)

New Westminster, B.C.—Tenders will be received by A. O. Powell, Harbor Engineer, 514 Westminster Trust Bldg., until December 2nd, 1912, for upwards of three thousand linear feet of cedar pile quay wall construction, and one million cubic yards of back filling with rock revetted slope. Plans and specifications may be examined at engineer's temporary office at Room 22, 26 Lorne Street, New Westminster. (See Advt. in The Canadian Engineer.)

Rock Island, P.Q.—R. C. Desrochers, Esq., secretary, Department of Public Works, will receive tenders for the erection of a post office and customs and inland revenue office, also interior fittings for the same up to 4 p.m., December 2nd next. Plans and specification to be seen on application to Mr. Jas. Lowell, Clerk of Works, Rock Island, P.Q.; Mr. H. N. Lymburner, Supt. of Buildings, Montreal, and at the Department of Public Works, Ottawa.

Toronto, Ont.—Tenders will be received by the Secretary of the Ontario Jockey Club, 6 Leader Lane, until noon of November 26th, 1912, for demolishing the brick building and addition on the grounds of the Ontario Jockey Club, known as Woodbine Park Hotel, Queen Street, East.

Toronto, Ont.—Bulk tenders, or tenders for the several trades mentioned below, in connection with a fire hall, will be received by registered post only, addressed to the undersigned, up to noon on Tuesday, 3rd December, 1912: 1, Mason; 2, carpenter; 3, plumbing; 4, heating; 5, roofing; 6, plastering; 7, electric wiring and light fixtures; 8, painting. Plans and specifications may be seen and forms of tender and all information obtained at the office of the City Architect, City Hall, Toronto.

Victoria, B.C.—The provincial public works department will receive tenders for the erection of a 4-roomed, brick schoolhouse at Black Mountain. All tenders to be in by noon, November 27th.

◆

CONTRACTS AWARDED.

Dunnville, Ont.—The Des Moines Bridge and Iron Company, of Des Moines, Iowa, U.S.A., were the successful tenderers on the construction of a steel elevated tank. Their price was $5.550.

Welland, Ont.—Messrs. W. G. Somerville & Sons have been awarded the contract for the construction of a sewer to the Empire Cotton Mills at a price of $5,446.90. The other tenders were: Excelsior Construction Co., $5,915.20; Peter McMurray, $5,826.91; Geo. Reid, $5,533.15. The Engineer's estimate of the work set the amount at $5,213.00.

Victoria, B.C.—Messrs. Hutchinson Bros. will be awarded the contract for the installation of primary feeders for cluster lighting on Government Street South, the company's bid of $1,856 being the only one received by the city.

◆

RAILWAYS—STEAM AND ELECTRIC.

Central Canada.—Messrs. Lewis and Smellie, Ottawa, state that an application will be made to the Parliament of Canada at its next session for an Act to incorporate a railway company under the name of "All Red Line Railway Company," with power to construct, lay out and operate a line of railway from a point at or near the easterly boundary of the Province of Quebec, thence in a westerly direction by the most feasible route through the Provinces of Quebec, Ontario and Manitoba to the city of Winnipeg, with branch lines.

◆

LIGHT, HEAT AND POWER.

Lower Ontario.—The Hydro-Electric Commission has signed power contracts with Brantford, Paris, Port Dalhousie, Brockville and Prescott.

Mirror Lake, B.C.—The members of this municipality have subscribed sufficient capital to cover the erection costs of an electric light plant. Mr. A. Link is one of the directors.

North Bay, Ont.—The politicians advocating the adoption of the hydro-electric by-law have been met with record audiences, and judging from present appearances the matter will be carried by the ratepayers.

Toronto, Ont.—Hon. Adam Beck, in an address before the Ontario Municipal Electrical Association, intimated that a reduction in Hydro-Electric power might be looked for by several municipalities.

Winnipeg, Man.—The municipal Fire, Water and Light Committee have ordered the extension of the Main Street cluster lighting system to the northern limits of the city.

◆

GARBAGE, SEWAGE AND WATER.

Berlin, Ont.—Chairman Piper, of the sewer committee, has reported on the cost of a trunk sewer for this city. According to his estimates the expenditure will be about $90,000.

London, Ont.—The report of Mr. A. E. Macgregor, who has been engaged for some time in preparing a topographical map of the city, is before the board of works. The maps, drawings, etc., showing the proposed storm sewers, were enclosed with the report, and gave the aldermen a definite idea as to what is needed. The estimated cost of the storm sewer construction is placed at $500,000.

Vancouver, B.C.—Mr. R. S. Lea, consulting engineer on the sewerage scheme, states that his report will be submitted this year. He states that sewage matter turned into English Bay will not prove a nuisance.

◆

BUILDINGS AND INDUSTRIAL WORKS.

Berlin, Ont.—A company taking the name of the Fibre Products Company has been organized with Mr. J. Walter as factory manager. The products of this firm will be furniture trimmings, electrical insulators and lavatory fittings.

Edmonton, Alta.—The Board of Governors of the University of Alberta will erect a new students quarters at a cost of $[illegible]

Edmonton, Alta.—It is reported that the directors of the Canadian General Electric Company are considering the erection of a branch plant at this point.

Edmonton, Alta.—The management of the Presto Heater Company, will erect a $50,000 factory in this city to house the manufacture of their products.

Guelph, Ont.—It is reported that Mr. Alex. Simmers, of Winnipeg, will consider the erection of a sheaf loader factory in this city.

Hamilton, Ont.—A company, financed by John Alden and Charles Palmer, of Rochester, N.Y., will erect a factory in this city for the manufacture of porcelain. The company will be known as the Canadian Porcelain Company, Limited.

London, Ont.—The management of the Findlay Electric Porcelain Company will locate in this city if given financial assistance.

London, Ont.—The management of the Dennis Manufacturing Company are making arrangements for the extension of their plant at a cost of $25,000.

Moose Jaw, Sask.—Mr. W. B. Sherman has submitted a set of theatre plans for the ratification of the building inspector.

New Denver, B.C.—The directors of the New Denver Fair are considering the enlargement of their present buildings. Mr. H. S. Nelson is chairman of this committee.

New Westminster, B.C.—The municipal council will erect a new jail and storehouse at a cost of $20,000. Ald. White, Lynch, Kellington and Curtis compose a committee that will deal with the matter.

Port Arthur, Ont.—Messrs. Seamen-Kent are making arrangements for the enlargement of their plant.

Port Arthur, Ont.—The Eureka Match Company will establish a plant at this point. Mr. Edward Stewart, New Westminster, is interested in this company.

Regina, Sask.—The municipal Finance Committee will assist Mr. M. B. Stein, of Montreal, to locate a factory in this city. The Board of Trade are interested in the matter.

Saskatoon, Sask.—The Massey-Harris Company, of Toronto, will erect a large warehouse in this city, Sir Lyman M. Jones, is president of this company.

Vancouver, B.C.—Messrs. Klaw and Erlanger announce that they will erect a theatre in this city at a cost of $500,000.

Vancouver, B.C.—The management of the Standard Dairy Company will erect a four-story building in this city at a cost of $70,000.

Winnipeg, Man.—The officers of the 34th Fort Garry Horse have purchased a building and will have the property altered for use as an armory. E. M. Fisher, is adjustant of this regiment.

◆

BRIDGES, ROADS AND PAVEMENTS.

Galt, Ont.—The ratepayers will vote on several paving by-laws at the next election.

London, Ont.—The Guest Bridge, over the Thames, has been completed at a cost of $20,000.

London, Ont—The municipal council have decided that the tenders for the West London bridge were too high and have ordered their return. New plans will be prepared with a view of cost reduction, and an invitation will be extended for other tenders. The prices as submitted ranged from $40,000 to $45,000.

St. Catharines, Ont.—A report states that the Federal government will consider the granting of $50,000 toward the cost of a bridge on King St.

South Vancouver, B.C.—The Board of Works will spend the sum of $14,845 on sidewalks and box drains. W. A. Clement, municipal engineer.

West and North Vancouver.—The councils of these municipalities are considering the erection of a bridge on the Keith Road at a cost of $30,000.

Victoria, B.C.—A deputation from the Doukhobor settlement at Brilliant, have requested that a bridge be erected and the Provincial Department of Public Works will, in all probability grant the request.

Victoria, B.C.—A new concrete bridge erected by the city over the ravine on the Gorge Road is completed at a cost of $25,000.

Barrett Specification Roofs

Shove Mills, Fall River, Mass. Roofed along the lines of the Barrett Specification in 1876.

Low Cost—Long Service

METAL roofs require painting every few years; most ready roofings require coating regularly, but with Barrett Specification Roofs *there is no maintenance expense.*

Barrett Specification Roofs are roofs of coal tar pitch and tarred felt, with a top surface of slag, gravel or tile, *laid according to the Barrett Specification.*

This specification is simply the standard formula for building a first-class roof of this character.

It is possible, of course, to make an inferior roof of these materials either by poor workmanship or by using insufficient and poor goods. But if the Barrett Specification *is followed absolutely and the materials called for are used*, you are certain of getting the best value in roof coverings.

Such roofs usually last twenty years and over without leaks or repairs.

Barrett Specification Roofs are almost universally used on factories and buildings of large roof areas and where costs are carefully figured. They are equally good for city dwellings, warehouses, railroad buildings, etc.

Copy of the Barrett Specification, with diagrams, mailed free on request to nearest office.

Special Note

We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired however the following is suggested.

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15, 1911, using the materials specified, and subject to the inspection requirements.

THE PATERSON MANUFACTURING CO., LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER ST. JOHN, N.B. HALIFAX, N.S.

CURRENT NEWS.

Brandon, Man.—Several of the civic officials and prominent citizens are agitating for a new post office.

London, Ont.—Among the money by-laws to go before the ratepayers, is one for $6,000 to be used for the purchase of factory lands and industrial sites.

New Glasgow, N.S.—John Underwood, mayor, and James Roy, clerk, of this municipality, will receive applications for the position of "Town Engineer." Applicants will state salary required, experience, and furnish testimonials. Parties who have specialized in permanent street building and hydraulic work will receive preference.

◆

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner of Canada, 17 Victoria Street, London, S.W., during the week ending November 4th, 1912:—

A Scottish firm make inquiry for names of Canadian importers of cement, building material and mining machinery.

Inquiry is made by a Belgian firm for the names of Canadian importers of iron and steel, wire nails, wood screws, barbed fencing wire, window, plate and table glass, woolen, cotton, linen and silk goods, cement, linseed oil, matches, white lead, etc.

From the branch for City trade inquiries, 73 Basinghall Street, E.C.

A London firm who are open to purchase considerable supplies of compo board invite offers from Canadian manufacturers.

A London firm manufacturing a specialty in office pastes seek representation in Eastern Canada and in British Columbia.

◆

CANADIAN PATENTS.

The following is a list of patents recently issued through the agency of Messrs. Ridout & Maybee, 59 Yonge Street, Toronto:—S. A. Horstman, spring wheels for road vehicles; F. Orbell, sheaf carrier for harvesting machinery; Birmingham Small Arms, Limited, air pistols or guns; Cooper Cap Co., caps; Tower Canadian, Limited, waterproof coats; E. S. Luard, steam superheaters; H. P. Roberts, beating and mixing devices; Harold Jarvis, nut lock; J. G. Robinson, steam superheater (transverse compartment header); J. G. Robinson, (two compartment header;) Bernard Hausheer, can filling machines; Wesley Castles, excavating machinery; Jerome C. Dietrich, hand saws; Jerome C. Dietrich, crosscut saw handles.

◆

IMPROVED PISTON PILE HAMMER.

A piston ram with very few moving parts has been placed on the market by the McKiernan-Terry Drill Company (Canadian representatives Canada Foundry Company), and would appear to have many points of interest to persons engaged in pile driving and other similar work. The moving parts consist of a spool valve, a check valve, the auxiliary accelerating piston and the main piston, all of a specific design which, according to the manufacturers results in an increase of efficiency of about 30 per cent. over many now on the market. They are made in sizes varying from 145 pounds to 4 tons.

◆

A CONTRACT IN THE BALKANS.

A report which is of unusual interest is made by Messrs. Laurie and Lamb, Montreal. This firm have been advised by Messrs, Heenan and Froud, Manchester, England, that one of their patent refuse destructor plants are to be placed at once in the town of Turn Severin, Roumania. This little news note suffices to show that the government authorities are not giving all their attention to the Turk, and are wisely disposing of waste matter at a time when such work is most called for.

NEW INCORPORATIONS.

West Vancouver, B.C.—West Vancouver Lumber Company, $10,000.

Haileybury, Ont.—Walsh Mines, $100,000. J. Walsh, W. R. Earle, V. Walsh, Cobalt.

Berlin, Ont.—Berlin Fibre Products, $40,000. J. Walter, D. Hibner, W. H. Schmalz.

Dryden, Ont.—Cleveland Gold Mining Co., $100,000. D. I. Grant, G. Grant, G. A. Urquhart.

St. Catharines, Ont.—Packard Electric Co., $1,000,000. R. B. Hamilton, G. C. Rough, M. J. McCarron.

Midland, Ont.—Simcoe Construction Co., $50,000. P. T. Murphy, Midland; A. J. R. Melville, J. Walmsley.

Pelee Island, Ont.—Pelee Island Navigation Co., $50,000. H. A. Henderson, F. W. Harris, E. Dieffenbach.

Burlington Junction, Ont.—Vera Chemical Co., of Canada, $150,000. G. H. Sedgewick, A. G. Ross, A. E. Langman.

Magog, Que.—Compagnie de Fonderie de Magog, (foundry), A. Tourigny, G. A. Brown, G. H. Patuo.

Ste. Elizabeth, Que.—Guilbault Freres & Compagnie, (cement products), $10,000. A. Guilbault, Ste. Elizabeth; W. Guilbault, Montreal; O. Guilbault, Ste. Elizabeth.

Hanover, Ont.—Fisher Machinery Co., $50,000. D. Knechtel, J. S. Knechtel, H. Peppler. Wilt Twist Drill Co., of Canada, $150,000. H. A. Springle, S. C. Robinson, W. Chater.

Vancouver, B.C.—Ceramics, $50,000. Middle West Lumber Company, $100,000. British Building Company, $250,000. Master Builders' Company, $1,100,000. S. Murchison & Company, (railway contractors), $50,000.

Toronto.—Bulldog Tires, $1,000,000. W. G. Moffatt, A. H. Crichton, J. Moffatt. Ontario Stone Co., $125,000. G. A. Hegy, T. A. Nicholson, W. S. McNamara. Park Feed Milling Co., $40,000. R. L. Westcott, L. Macaulay, J. E. Anderson. Dominion Wheel and Foundries, $250,000. G. Ruel, R. H. M. Temple, S. P. Biggs. Merrill Company, (manufacturing chemists), $500,000. F. W. Merrill, G. M. Miller, R. A. Somerville.

Montreal.—Belfour, Morris and Willcocks, (manufacturers agents), $200,000. W. R. L. Shanks, F. G. Bush, G. R. Drennan. Invention and Promotion, (mining), $100,000. A. J. Lavoie, R. Chenevert, F. Callaghan. Butters Salvador Mines, $750,000. J. J. Meagher, H. N. Chauvin, H. E. Walker. Franey Gold Mining Company, $500,000. E. Desmarais, J. Lacroix, D. Therriault. Ontario National Brick Company, $2,000,000. E. R. Parkins, W. Taylor, S. Greenshields Dixon. Domestic Brick and Tile Company, $500,000. H. Lampard, Westmount; J. A. Major, Verdun; H. M. G. Bellew, Montreal. Montreal Bed and Mattress Factory, $250,000. E. A. Mumford, S. W. Hicks, R. T. Stackhouse. Manitou Iron Mining Co., $100,000. M. A. Phelan, W. Bovey, R. Fleet.

HIGH ELASTIC LIMIT.

We have pleasure in publishing the following letter from Mr. W. A. Cook, manager of the Steel Products Department of Steel and Radiation, Limited, Fraser Avenue, Toronto. The many merits of Steelcrete are well known, and we are glad to note that one of the leading features of the reinforcement is even better than had been supposed:

"With reference to our advertisement appearing on page 75, your issue of November 14, it is stated:

"'The high elastic limit of Expanded Metal—60% of its ultimate strength.'

"Will you kindly change this in your next issue and place the percentage as equal to 85% of its ultimate strength. This has been satisfactorily proven by exhaustive tests made in various laboratories, and we are not claiming too much in rating it at this percentage."

ALBERTA, PEACE RIVER & EASTERN RAILWAY.

A new railway from the Pacific to the Hudson Bay is the ambitious project of the Alberta, Peace River and Eastern Railway. The length of the proposed line is 1,600 miles. The management of the new company in Canada is under Mr. H. Muskett King, who will make his headquarters in Ottawa, and Mr. E. G. Rykert, of Montreal. This board will shortly be increased by several. A feature in connection with the new railway is a colonization scheme, whereby it is proposed to introduce into the Dominion a large number of experienced agriculturists with their families, a special recommendation for whom will be that they are British subjects with a certain amount of capital. The English directors, in addition to being connected with the railway project, are also closely identified with several other companies which will work in affiliation with the new railway, [illegible] a land company, a flour milling company, a colonization, a freight motor and agricultural implement company.

CANADIAN RAILWAY CLUB.

The members of the Canadian Railway Club, Montreal, were addressed on the occasion of their last monthly meeting by Professor V. I. Smart, of McGill University, who read a paper on "Preventable Accidents."

Professor Smart's main contention was that it was shown by statistics that under present conditions in Canada travellers stand eighty-nine chances of being killed in railway accidents and twenty of being injured to one chance in Great Britain, and one-fourteenth of a chance in New South Wales, while in the United States they stand over twenty chances of being killed and sixteen of being injured. A comparison of conditions in the various countries was instructive. He divided the causes of accidents under three heads, firstly, malicious interference of chance obstruction, which source of danger could be largely lessened by strict enforcement of the law of trespass; secondly, failure of the track or equipment, which lead to numerous mishaps, and thirdly, mistakes or negligence on the part of those in charge of trains.

He was in favor of the installation of the hand operated block system, which, he said, would not be any more expensive than the automatic, in spite of the additional number of signalmen, as the plant was far cheaper. Since the introduction of the automatic, there had been no diminution in the total casualities, and this was due to the introduction of the block system on top of the time table system, and a certain confusion resulting. A well-nigh perfect system would be produced if the apparatus in use in England was introduced, with certain improvements and additions which are new features of the automatic.

In the discussion that followed Mr. C. W. Parker, of the Canadian Pacific Railway, said the block system was more adapted to double tracks than to single, while Canadian railways were mostly of the latter description. Also that the long mileage of the Canadian tracks and the consequent long blocks that there would have to be, would make it difficult to dispatch traffic regularly.

Mr. Ord, of the Canadian Pacific Railway, emph[illegible] the fact that weather conditions were an important factor in the working of a railway, and that in the winter months the number of accidents due to failure of equi[illegible] large compared with the summer. Again, if the railways spent as much in Canada in equipment as in England the cost of travelling would be prohibitive, and population would not increase. The expense of the block system in Canada would not secure a corresponding increase in safety.

REASONS FOR BULK SHIPMENT OF CEMENT.

Some reasons for the shipment of cement in bulk are given in a circular recently sent out by one of the large United States Portland cement companies. They are:

IT WILL COST LESS TO FINANCE THE JOB.—The initial outlay for bulk cement will be 40 cents per barrel less than for cement in cloth sacks and 10 cents less than for cement in paper. Every cloth sack on a job, or in transit to or from a job, whether filled or empty, represents an investment of 10 cents. Every paper bag used represents a fixed loss of 2½ cents.

IT WILL GET TO YOU IN BETTER SHAPE.—There will be no fuss or argument over sacks received in torn condition. If rain should get into the car, there will only be one or two lumps of set cement to be lifted out; there will be no partially damaged sacks to handle and no lumps of set cement to be pried out of sacks.

IT WILL COST LESS FOR LABOR.—No matter how cement is bought, it is bulk cement that goes into the mixer. Therefore, labor employed in emptying sacks, that is, reconverting sacked cement into bulk cement, is wasted labor. So is the labor that is spent in shaking, counting, bundling, shipping and keeping track of empty sacks, for there is no real reason why there should be any sacks on the job.

IT WILL COST LESS FOR MATERIAL.—In computing the total cost of cement used on the job, the various sack losses and expenses must be added to the invoice price of the material—therefore, eliminate this loss and expense and reduce the cost of cement. If sacks are used some of them must surely be destroyed, through carelessness, wilful abuse and natural wear and tear, and some of them will probably be stolen. All these destroyed and stolen sacks cost money; why not get along without sacks?

IT WILL COST LESS IN THE WAY OF MISCELLANEOUS EXPENSES.—There will be no freight to pay on returned sacks. The sack shed can be used for storing something that is really needed on the job—or need not be built at all. The team can be doing something worth while instead of hauling sacks to the depot. The bookkeeper and clerks won't need to be keeping tab on a lot of sacks which run into big money and don't do the job any good. After they have put in part of the time formerly devoted to this kind of work in figuring the profits resulting from the use of bulk cement, they can spend the rest of the time in figuring further ways of cutting costs and increasing profits.

IT WILL IMPROVE THE DISCIPLINE ON THE JOB.—Cement sacks are very attractive to men. Split open, they make good aprons. If a man is working in mud, a couple of sacks wrapped around his feet will protect his shoes. In rainy weather a sack will keep his shoulders dry. Sacks are handy as tool bags and for carrying nails, rivets, etc. Lots of them are stolen. All these sacks cost the user of the cement 10 cents each, and, furthermore, if the men are allowed to get into the habit of misappropriating one kind of property they won't stop there. Soon, belting will be cut up for hand shields, tools will be misused and other valuable property made away with.

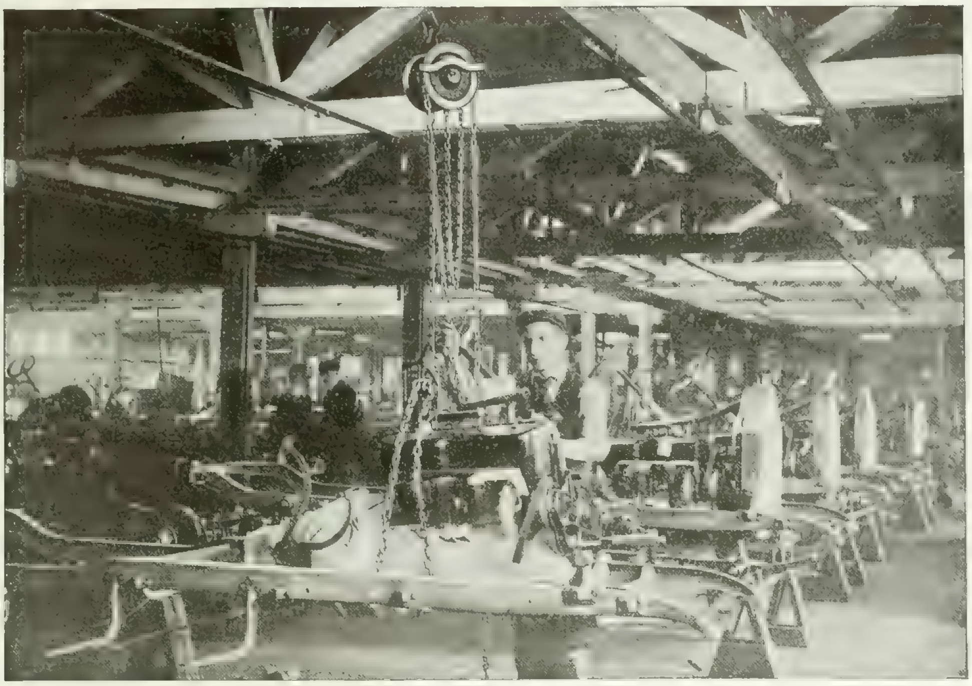
HONOR FOR SANITARY OFFICIAL.

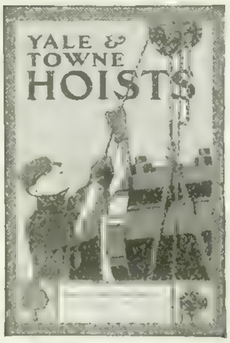
The Royal Society of England recognized the sanitary administration of the works of the Panama canal by awarding its Buchanan medal to Col. William G. Georgas, U.S.A., chief sanitary officer of the Panama canal zone.

THE TRIPLEX BLOCK



Placing engine in chassis with a half-ton Triplex Block.

A 100-page Book on Hoists



Practical engineers are all agreed that radical cuts in cost can be brought about by solving hoisting problems. Such problems are not solved satisfactorily by heavy cranes which do not give continuous service. A load that is waiting to be moved is costing money just as much as a load which is taking a gang of workmen to move.

A hoisting problem is not solved until each workman can readily lift and transport any load, single handed, that comes to him.

The new Book of Hoists shows examples of hand and power hoisting and overhead apparatus for conveying in model plants, here and abroad. The information is the most complete we have ever published. We will be glad to send a copy free on request.

Triplex { **16 Sizes:** One-quarter of a ton to forty tons. } **Every Block Tested**
Blocks; { **300 Active Stocks** all over the United States. } **to 50% Overload.**

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

17929—November 2—Directing G.T.R. repair and extend to the highway, the centre platform at Bulstrode Station, Que., and that the culvert be put in a proper state of repair.

17930—November 4—Approving revised location Central Ry. Co. of Canada from mileage 0 to mileage 5, in city of Montreal, P.Q., on condition that grade at crossing at St. Michel Road be eliminated.

17931—November 4—Authorizing C.N.O.R. to cross jointly with the Lachine, Jacques-Cartier and Maisonneuve Ry., under the tracks of the C.P.R., near Jacques-Cartier Jct., Que.

17932—November 5—Authorizing C.P.R. to open for traffic its Wilkie Southwesterly Branch from Wilkie, mileage 0, to Anglia, mileage 35.3.

17933—November 5—Approving proposed location G.T.P. Branch Lines Co., station at Beiseker, on its Tofield-Calgary Branch, in Sec. 12, Tp. 28, R. 26, W. 4 M.

17934—November 4—Authorizing C.P.R. to construct across fifty-eight (58) highways from mileage 22.7 to mileage 106.2 on its Pheasant Hills Branch.

17935—November 5—Directing C.P.R. (Havelock Subdivision) to install improved type of automatic electric bell at crossing at east end of its yard at Sharbot Lake, Tp. Oso, Co. Frontenac, Ont.

17936—November 6—Authorizing G.T.R. to construct siding, commencing north of Port Robinson Station, to the premises of the Standard Steel Construction Co., Ltd., Welland, on part of Lot 203, Tp. Thorold, Co. Welland, Ontario.

17937—October 24—Authorizing the town of Pointe aux Trembles, Que., to extend at its own expense, St. Jean Baptiste St., across Can. Nor. Que. Railway.

17938—October 24—Authorizing the town of Pointe aux Trembles, P.Q., to extend, at its own expense, First Ave., across the Can. Nor. Que. Railway.

17939—November 7—Directing that the cost of installing the gates at the crossing of Main St., Victoriaville, P.Q., be divided as follows:—20 per cent. out of "The Railway Grade-Crossing Fund," 30 per cent. by the Municipality of Victoriaville, and 50 per cent. by G.T.R.; and that cost of maintaining same be borne and paid, 70 per cent. by Railway Company and 30 per cent. by the Municipality.

17940—November 7—Authorizing C.N.Q.R. to construct across two (2) highways on its St. Eustache-St. Jerome Line, in County of Two Mountains, Quebec.

17941—November 6—Authorizing C.P.R. to open for traffic its second track from Secretan, mileage 44.9 to Chaplin, mileage 54.

17942—November 9—Authorizing G.T.R. to take certain lands in St. Antoine Ward, city of Montreal, Que., for the convenient accommodation of the public and the traffic carried over its railway.

17943—November 9—Approving by-laws passed by the Marconi Wireless Telegraph Company of Canada, Ltd., authorizing J. H. Lauer, general manager of the company, to prepare and issue tariffs of tolls to be charged by said company.

17944—November 7—Directing G.T.R. to install an improved type of automatic electric bell at crossing just west of Vineland Station, Ontario.

17945—November 7—Authorizing C.P.R. to construct spur for N. K. Fairbank Co., Ltd., on original Lot Cadastral No. [illegible] (now known as Lot Cadastre No. [illegible]), Parish of Lachine, Co. Jacques Cartier, Quebec.

17946—November 7—Authorizing C.P.R. to reconstruct bridge No. 13.9, Owen Sound Sub. Div., Ontario Division.

17947—October 19—Authorizing N. St. C. & T. Ry. to construct its Beamsville Extension across five (5) highways, Twp. of Louth, Co. Lincoln, Ont.

17948—November 5—Authorizing N. St. C. & T. Ry. to construct across twelve (12) highways, Twps. Grantham and Niagara.

17949—November 8—Authorizing C.L.O. & W. (C.P.R.), to construct across Front St., town of Trenton, Ont., mileage 88.14 from Glen Tay ,by means of a bridge.

17950—November [illegible]—Refusing application of the Municipality of Borden, Sask., to extend Sheppard St. across C.N.R.; and authorizing said municipality to cross C.N.R., just east of west switch in the village of Borden, Sask.

17951—November [illegible]—Refusing application C.P.R. for approval of station at mileage 17.5, Virden-McAuley Branch, on S.W. ¼ Sec. 3, Tp. 13, R. 27, W. 1st M., Manitoba; and approving location at mileage 21.5, Virden-McAuley Branch.

17952—November 8—Authorizing C.P.R. to divert highway adjoining West Boundary of [illegible], Tp. 11, R. [illegible], W. 4 M., in a southwesterly direction, to connect with highway adjoining South Boundary S.E. [illegible], Sec. [illegible], Tp. 11, R. [illegible], W. 4 M., Alberta.

[illegible]—November [illegible]—Approving C.L.O. & W. (C.P.R.) plan showing bridge proposed to be erected at mileage 129.68, across road allowance between Lots 16 and 17, Con. [illegible], Tp. of Hope, Co. Durham, Ont.

[illegible]—November 8—Authorizing G.T.R. to construct additional track across [illegible] Road, Tp. [illegible], Co. Welland, Ont.

[illegible]—November [illegible]—Authorizing G.T.R. to alter and extend existing siding to premises of Vineland Canning Co., Ltd., Vineland, Ont.; and to construct additional siding for said Vineland Canning Co., Ltd., on part Lot [illegible], Con. [illegible], Tp. Louth, Co. Lincoln, Ont.

[illegible]—November [illegible]—Authorizing N. St. C. & T. Ry. to construct its Beamsville Extension across eight (8) highways, Twp. of Clinton, Co. Lincoln, Ont.

[illegible]—November [illegible]—Approving revised location [illegible] Bay and [illegible] tern [illegible] station [illegible] Tp. of [illegible], Co. Lake [illegible] mileage [illegible] from [illegible].

17958—November 8—Authorizing C.P.R. to take, for the purpose of securing the efficient construction, maintenance, and operation of its railway, certain lands in Notre Dame de Grace Ward, city of Montreal, Que.

17959—November 5—Directing V.V. & E. Ry. & Nav. Co. to protect that portion of railway between Ocean Park and White Rock as follows: one night-watchman between mile posts 123 and 125, and one night-watchman between mile posts 125 and 127; company's sectionmen to protect park during the day time by going over the ground at least twice a day.

17960—November 9—Approving loaction C.N.R. through Tp. 2, Rgs. 6-8, W. 2 M., Sask., mileage [illegible] to mileage 8.02.

17961—November 8—Directing G.T.R. to provide an electric bell at Woodbine Avenue, Toronto, Ontario.

17962—November 8—Authorizing the North American Smelting Company, Limited, to construct an aerial tramway and an electric power transmission line over and across C.N.O.R. on Lot 16, Con. 9, Tp. Loughborough, Co. Frontenac, Ontario.

17963—November 9—Authorizing C.P.R. to construct sewer and water pipes across East Kildonan Road or Kelvin Avenue and Bird's Hill Road or Panet Road; and amending Order No. 17391, dated August 30th, 1912.

17964—November 7—Authorizing C.P.R. to construct spur for J. H. Preston Planning Mills Company, city of Medicine Hat, Alta.

17965—November 8—Relieving M. C. R.R. from providing further protection at Sixth Concession Road, near Leamington, Tp. of Mersea, Ontario.

17966—November 8—Approving G.T.P. Branch Lines Co., location of proposed station at Frobisher, Regina-Boundary Branch, Sec. 13, Tp. 3, R. 4, W. 2 M., Saskatchewan.

17967—November 8—Approving revised grade of G.T.P. Branch Lines Company, from mileage 21 to mileage 23, Rural Municipality of Cornwallis, Dist. Brandon, Man., and rescinding Order of the Board No. 17758, dated October 14th, 1912.

17968—November 8—Approving location and detail plans of G.N. Ry. Co's. proposed station and detention house at city of Rossland, British Columbia.

17969—November 5—Extending, until April 30, 1913, the time within which the C.N.O.R. install the permanent interlocking plant where is crosses G.T.R. and C.P.R., near Ottawa.

17970—November 5—Refusing application C.P.R. for an Order rescinding Order of the Board No. 16838, dated June 20, 1912, dispensing with services of night watchman where C.N.O.R. crosses St. Lawrence and Ottawa, east side of Rideau River, near Ottawa.

17971—November 11—Approving location C.N.O.R. station grounds at Chisholm, Twp. Chisholm, Ont., mileage 210.

17972—November 8—Relieving G.T.R. from providing further protection at highway three miles East of Brighton, at mile post 238, Municipality of Smithfield, Co. Northumberland, Ontario.

17973—November 11—Authorizing C.P.R. to construct its Swift Current Southeasterly Branch across highways adjoining North and East boundaries, Sec. 10, Tp. 11, R. 6, W. 3. M., at mileage 69,29; and to divert highway adjoining North Boundary in a southeasterly direction to connect up with highway adjoining East boundary, Sec. 10.

17974—November 11—Amending Order No. 17921, dated October 31, 1912, by striking out the words, 'subject to the terms of the said consent', in first line of operative part of Order.

17975—November 11—Authorizing C.N.O.R. to construct across Cormanville Street, town of North Bay, Dist. Nipissing, Ottawa-Capreol Line.

17976—November 14—Extending until November 28th, 1912, the time within which the British Columbia Electric Railway Company appeal to the Supreme Court of Canada from Order No. 17840, dated October 14th, 1912, and in the meantime staying all proceedings under said Order.

17977—November 12—Authorizing G.T.P. Branch Lines Company to construct extension of industrial spur into town of Yorkton, Sask.

17978—November 12—Approving revised location G.T.P. Ry. mileage 108.8 to mileage 111.29, east of Prince Rupert, Rge. 5, Coast District, through Chin de Mash Indian Reserve, B.C.

17979—November 12—Approving revised location G.T.P. Ry. from mileage 157.51 to mileage 170.84, east of Prince Rupert, Cassiar Dist., through Kitsegucla No. 1 and Andimaul Indian Reserve, B.C.

17980—November 12—Approving G.T.P. Branch Lines Company station site and station at Duff, Melville-Regina Branch, Sec. 8, Tp. 22, R. 8, W. 2 M.

17981—November 12—Approving location G.T.P. Branch Lines Co., station at mileage 142, Regina-Boundary Branch, Sec. 26, Tp. 2, R. 3, W. 2 M., Sask.

17982—November 12—Authorizing G.T.R. to construct siding for the Canadian Billings & Spencer, Ltd., Lot 23, Con. 4, Tp. of Crowland, Co. Welland, Ont.

17983—November 13—Authorizing C.N.O.R. to construct across Sixteen Mile Creek, Tp. Trafalgar, Co. Halton, Ont., mileage 23.45 west from Toronto.

17984—November 12—Authorizing C.N.O.R. to construct across public road, between Con. 2, Tp. of Westmeath, and Con. 2, Tp. of Pembroke, Co. Renfrew, Ont.

17985—November 12—Authorizing C.N.R. (Vegreville-Calgary Extension), to construct over and across Secondary Canal "A," Sec. 2, Tp. 24, R. 28, W. 4 M., mileage 247.5.

17986—November 12—Authorizing C.N.R. (Vegreville-Calgary Branch), to construct over and across Secondary Canal "B," South Branch, Sec. [illegible], Tp. [illegible], R. 27, W. 4 M., mileage [illegible].

17987—November 12—Authorizing C.N.R. to construct Calgary Southerly Branch across public road between Secs. 6 & 7, Tp. 21, R. 28, W. 4 M.

17988—November 12—Authorizing C.N.R. to construct Calgary-Southerly Branch across public road between Sec. 25, Tp. 21, R. 29, & Sec. 30, Tp. 21, R. 28, W. 4 M., by means of undercrossing.

17989—November 12—Authorizing C. L. O. & W. (C.P.R.) to construct bridge No. [illegible], Tp. Richmond, Co's. Lennox and Addington, Ontario.

17990—November 13—Approving revised location C.L.O. & W. (C.P.R.), from mileage [illegible] to mileage [illegible].

17991—November 12—Authorizing C.P.R. to construct spur for the McPherson Fruit Co., Calgary, Alberta.

Volume 23. Toronto, Nov. 28, 1912 Contents of this issue on page 781

The Canadian Engineer

An Engineering Weekly

THE VANCOUVER ISLAND POWER COMPANY, LIMITED, JORDAN RIVER DEVELOPMENT.

PART I.

Western Canada is growing with such rapidity, particularly the southern coast districts of British Columbia adjacent to the cities of Vancouver and Victoria, that in these communities it has been for some time a serious problem with the public utilities companies to keep pace with the rapidly increasing demand for service.

The British Columbia Electric Railway Company, Limited, owning and operating the traction, lighting, and power systems of Vancouver and Victoria, and territories adjacent thereto, has been for the past five years laboring with this problem. The growth and expansion of the districts which this company is serving have been phenomenal, and the demand for power has been multiplied several times within that period. The capacity of British Columbia Electric Railway Company's plants has been increased constantly, both in steam and water power, and generally in time to anticipate requirements.

As early as 1907 it was realized that material increase in power capacity would be required by the Victoria branch, but that this could be met within a period allowing adequate investigation of the available water power resources on the southern end of Vancouver Island, and the installation of a modern, well equipped hydro-electric power system.

At the time the Jordan River development was actually begun, the British Columbia Electric Railway Company was serving Victoria and adjacent territory with electricity from a steam station in Victoria of 800 kilowatt capacity and a hydro-electric station of 2,000 kilowatt capacity at Goldstream, about ten miles out of the city. The latter plant was operated with surplus water purchased from the Esquimalt Water Company, and could run at full capacity only during a part of the year on account of water shortage.

Mr. Wynn Meredith, then consulting engineer for the British Columbia Electric Railway Company, was authorized to investigate the available power possibilities, and under his direction an exhaustive series of investigations were carried out, which included practically all the sources of water power within a radius of commerciably feasible transmission to the city of Victoria. This preliminary work was continued for upwards of a year, and was accomplished under the most extraordinary difficulties, the investigation in many cases being more properly explorations of an unmapped and practically unknown region, untraversed, except for a narrow fringe of coast line, beyond the occasional visit of trapper or timber cruiser. Pioneer work in the forests of British Columbia can only be properly appreciated by those who have undertaken it. Water powers are abundant, but the wild, rugged and inaccessible character of the country renders it difficult in the extreme to acquire even very limited preliminary knowledge of a possible water power development. Most of the virgin country is covered with heavy timber, sometimes cruising 600,000 feet, board measure, per acre; and whether timbered or not the ground is covered with a dense growth of brush and fallen and rotting trees.

The Jordan River Development, Bear Creek Dam.

The hardships endured by the engineers on reconnoissance work, their heart-breaking conquest of the jungles, struggling with pack on back through the proverbial "impenetrable" British Columbia forest, blazing many paths in order to insure safe retreat in case further advance was impossible, or to retrace the course if promising conditions were discovered, have become a part of the history of the "job," and to the preserverance and hardihood of these pioneers the successful culmination of the investigation is largely due.

An examination of the upper watershed of the Koksilah River in the latter part of 1907 led to the first consideration of a possible power development on the Jordan River, the head waters of which lie adjacent to, and only separated by a few hundred yards from the source of the Koksilah. A visit to the mouth of the Jordan on the west coast of the island, a few weeks later, disclosed a large and rapid stream, further exploration of which was prevented at the time by the absence of trails and prevailing wet season, which renders pioneer work in this country almost impossible. A gauging station was, however, established near the mouth of the stream, and a series of observations of run-off instituted.

Early in the spring of 1908, a party of engineers was engaged to explore thoroughly the river and all its branches, investigate the possible reservoir sites, and ascertain in a preliminary way the head or fall obtainable.

This information was gathered during the summer, and in November, 1908, Mr. Meredith, who had in the meantime entered the firm of Sanderson & Porter, engineers, of New York, then made a formal report on the project, having determined that the watershed with the run-off observed, and the use of certain storage reservoirs which had been discovered would, with the head available, amply warrant development for power purposes. Sanderson and Porter were then retained as engineers for the British Columbia Electric Railway Company, Limited, to design and construct the Jordan River power development.

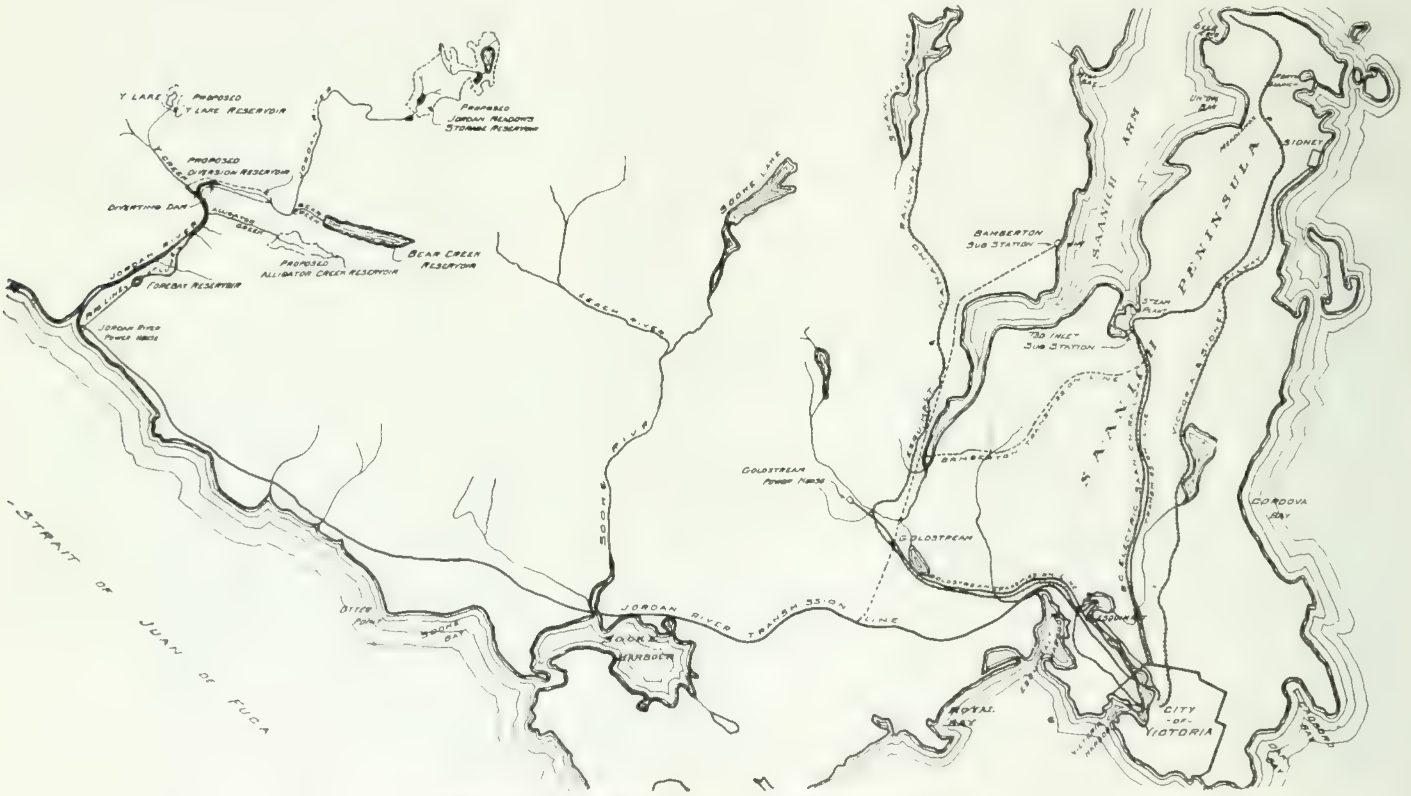
A subsidiary corporation, known as the Vancouver Island Power Company, Limited, was formed under the auspices of the British Columbia Electric Railway Company to finance and otherwise assume charge of the project.

The Jordan River flows into the Straits of Juan de Fuca at a point about 40 miles west of the city of Victoria. It is one of the large streams on Vancouver Island, the drainage area being about 75 square miles, the greater part of which lies above an elevation of 1,200 feet. The source of the main river is at Jordan Meadows, which lies about midway between the east and west coasts of the island at an elevation about 1,700 above sea-level.

Three large tributary streams join the main river in the upper 10 miles of its course, Bear Creek and Alligator Creek from the east, and "Y" Creek from the west, forming a high level watershed, the entire run-off from which is available for power purposes.

The entire watershed is covered with a very heavy growth of timber, and at the higher levels receives each year a covering of snow from 4 feet to 7 feet in depth, which is gradually melted in the spring, but does not, as a rule, entirely disappear until June or July.

British Columbia is noted for excessive precipitation, and great changes in amount of precipitation in short distances. On the mainland near Vancouver an annual precipitation of 160 inches has been observed, and a variation of 100 per cent. in annual precipitation has been noted in the same season at points only a few miles apart.



Map of the Southern End of Vancouver Island.

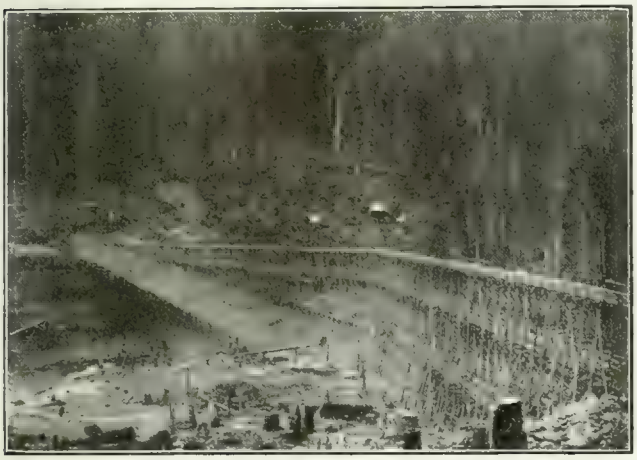
Showing the Jordan River Development in relation to the City of Victoria.

The average precipitation over the entire Jordan River watershed, as shown by observations extending over a period of four years, is about 80 inches.

The development has the usual features of storage reservoirs, diverting dams, flumes, forebay reservoir, pressure pipes, power house, transmission lines, and sub-station, but the extraordinary conditions under which the work was accomplished, the development of special methods of meeting the abnormal conditions governing the work, and the details of the execution under these conditions possess more than passing interest.

The Jordan River has a wide variation between summer and winter flow. The highest portion of its watershed is not more than 2,700 feet in elevation. The area possesses features especially calculated to conserve the precipitated waters, more particularly in the dense jungle of forest and underbrush with which it is clothed, the mat of forest floor from 1 foot to 2 feet in depth overlying the soil, the retarded melting of the snow due to the dense shade of the forest, and the moderate transverse slope of the mountain sides. All of these features, however, do not prevent a period of extremely low water, for some 60 to 90 days in the summer and fall of each season.

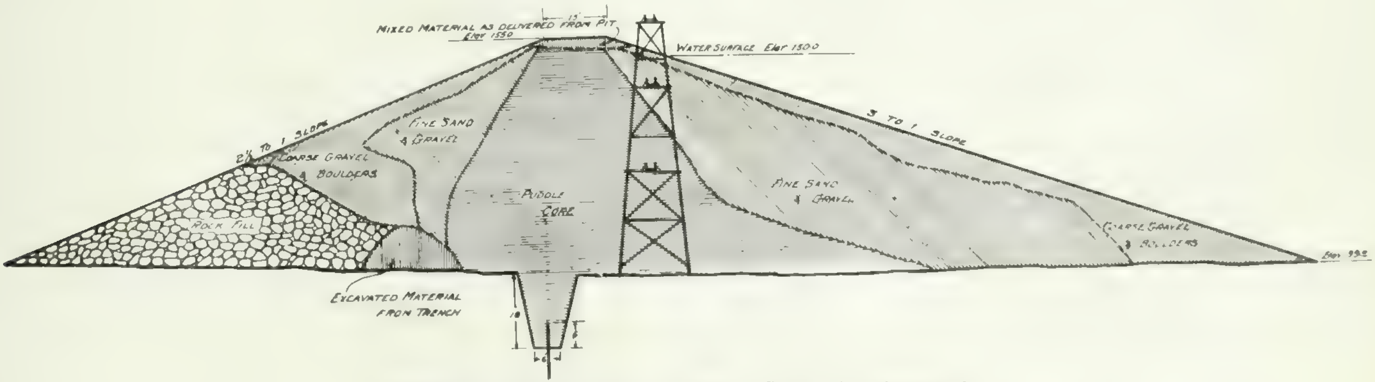
The stream flow has been systematically observed since 1907, and the results obtained more than sustain the findings of the original report in which the maximum power production of the watershed, based on a 50 per cent. load factor, was placed at 24,000 horse-power, with the commercially feasible storage available.



The Bear Creek Dam Nearly Completed.

It was seen at the beginning of the investigation that a large storage capacity would be required to impound flood waters for use during the dry season. Five favorable reservoir sites were found in the flats and meadows along the upper reaches of the river and its branches. The capacities of these storage basins and the sizes of the impounding dams required have been determined, and the results show that ample storage capacity is available, within reasonable cost, to provide for an ultimate maximum plant output of 24,000 to 36,000 horse-power. These reservoir sites are as follows:

	Height dam.	Capacity, cubic feet.
Bear Creek (initial developent)	55 ft.	320,000,000
Bear Creek (ultimate development) ..	75 ft.	608,000,000
Alligator Creek	35 ft.	95,000,000
"Y" Creek	35 ft.	110,000,000
Jordan Meadows	35 ft.	179,000,000
Diversion Storage	85 ft.	250,000,000



Section of Earth Dam on Jordan River Development.

The 12 . 40 lb. Carnegie steel sheet piling, shown at the bottom of the dam, goes down to bed rock.

One impounding dam is now completed at Bear Creek reservoir and the other storage sites can be developed as additional generating units are installed to meet the increasing power requirements.

Bear Creek Reservoir.—This reservoir site lies near the head waters of Bear Creek, the dam being about a mile above the junction of that stream with Jordan River, about 4½ miles by wagon road from the diverting dam, and some 13 miles from the power station at the beach.

The impounding basin is formed in the long and comparatively narrow valley of Bear Creek, through which the stream winds in a succession of sluggish pools for a distance of some two miles above the site of the dam. The sloping sides of the valley are chiefly of broken and partially metamorphosed slate, covered with soil to a depth of from three to six feet. As the flat bottom of the valley is approached, the bed rock dips gradually from either side toward the centre of the valley, and is topped with a layer of hard-pan—a semi-cemented glacial gravel mixed with clay. This attains a depth of 87 feet in the ancient bed rock channel, which at the dam site is some 300 feet north of the present stream bed. The entire reservoir area supports a heavy growth of fir, spruce, hemlock, red cedar and yellow cedar timber.

The drainage area above the dam is about 8 square miles in extent, gently sloping, and rising to an altitude of about 2,300 feet.

The average precipitation observed at the site during the past two seasons is about 85 inches. In the winter months this precipitation takes the form of snow, which accumulates at times to a depth of 7 feet in the reservoir area.

Until the preliminary construction work began this site was unexplored, except for the rough preliminary survey which had been made in 1908 to determine the general features of the project. In September, 1910, the construction of a wagon road from the diverting point to the dam site was begun, and it was only after its completion late in November of that year that a permanent camp could be installed, and steps taken to determine with certainty the nature of the material underlying the dam site, and the quantity and quality of the material available for the construction of the dam.

The winter and spring of 1911 were spent in investigating the dam site, and the sites for borrow pits. A series of test pits were sunk and borings taken, and in May, 1911, complete data was obtained from which the construction details could be planned.

The principal dimensions of the dam and reservoir are:

Greatest height above bottom of valley	57 ft.
Greatest height above bottom of sheet piling curtain	127 ft.
Length of crest of dam	1017 ft.
Greatest depth of cut-off trench	31 ft.
Top width of dam	15 ft.
Width of spillway	50 ft.
Depth of spillway below high-water level	10 ft.
Upstream slope of dam	3 to 1
Downstream slope of dam	2½ to 1
Total volume of dam (embankment measurement)	148,390 cu. yds.
Capacity of reservoir above outlet gates with high-water level 5 ft. below crest of dam	320,000,000 cu. ft.
Area of reservoir at high-water level	284 acres
Drainage area above dam (approximate)	8 sq. miles

The Intake Tower in Forebay Reservoir.

In prospecting the site of the dam to determine the nature of the underlying material, a trench 16 to 20 feet in depth was excavated along the entire length of the dam axis, and following the top of the bed-rock as far as the depth of the trench would safely permit. Test holes were put down in the bottom of the trench by driving 3-inch pipe casing to the bed-rock. The casing was sunk with churn drills operated inside the casing, the material being removed with a water jet.

The formation was found generally to consist of a stratum of top soil from two to three feet in thickness, underlying which was a mass of heavy gravel and boulders. At a depth of from 12 to 16 feet the boulders diminished in size, and gave way to coarse, partly cemented gravel, hard enough to offer considerable resistance in removal with picks, below which, and at a depth of about 20 feet, alternating layers of loose sand and gravel carrying water extended to the bed-rock.

With these foundation conditions determined, and in order to provide not only a square foundation for the initial structure 55 feet in height, but for an ultimate structure which would raise the water level 70 feet above the floor of the valley, and double the capacity of the impounding basin, it was decided to install a curtain of steel sheet piling extending to the bed-rock.

After thoroughly prospecting both slopes of the valley, a sufficient amount of suitable material for building the embankment was found on the north side, directly opporite the dam, and distant about 400 feet from the north end of the dam axis. The material consisted of the hard-pan common to the district, gravel and sand mixed with clay, favorably proportioned for sluicing from place into the fill. The borrow pits were 150 to 250 feet in elevation above the valley floor, and afforded a working face or bank 8 to 18 feet high.

Clearing the timber from the dam site and the adjacent areas was begun as soon as men and equipent could be placed on the work. Powder and donkey engines were used extensively in removing stumps and piling the timber and debris for burning. A single acre in the dam site was found to contain 240 stumps of a size to require blasting for removal. The flowage area was not cleared beyond the immediate vicinity of the dam where clearing was required for construction purposes.

After the clearing was finished, and the stumps removed, the forest floor, consisting of partly decomposed vegetation, rotten wood and smaller roots, was removed to a depth of one to two feet from the area to be occupied by the base of the dam. Thirty acres of ground were cleared in all, 10.1 acres of which were stumped, and 4.1 acres stripped.

A cut-off trench, 6 feet wide at the bottom, 10 to 31 feet deep, with side slopes about ¾ to 1, was excavated parallel to the axis of the dam, the centre line of the trench being directly under the downstream edge of the crest of the embankment. The material excavated from the trench consisted of heavy boulders, gravel and sand. Steam and hand-derricks with skips were used in the dryer parts of the trench, while the section under water near the stream bed was removed with an hydraulic elevator. The total volume of material removed was 8,675 cubic yards

Interlocking steel sheet piling—Carnegie 12-inch 40-lb. section—was driven in the bottom of the cut-off trench to the slate bed-rock. Two pile drivers with 2,000-pound drop hammers were used, the driving gangs working night and day. The piles were furnished in lengths of 50 feet and less, the first shipment arriving at the site August 6th, 1911. Hard driving was encountered on the north side of the creek, but no pile was left until it reached bed-rock as indicated by the test holes. The piles were driven along the centre line of the cut-off trench, and from 4 to 6 feet were left projecting above the bottom. The trench was thoroughly cleaned before sluicing was started.

Total number of steel sheet piles driven	616
Total length of steel cut-off	580.5 feet
Net length cut-off per pile	about 11½ in.
Maximum penetration of pile below bottom of cut-off trench	68.5 feet
Average penetration of pile below bottom of cut-off trench	about 46.3 feet
Maximum penetration of pile below original ground surface	87.0 feet
Total piling driven	28,509.0 feet
Total weight of piling	570 tons

A permanent flood water spillway having a net opening 50 feet wide by 10 feet deep below the high-water level of the reservoir, was excavated in solid slate bed-rock around the north end of the dam. The spillway cut was about 350 feet in length by 35 feet maximum depth, with side slopes ¼ to 1. The larger part of the work was done under contract before sluicing was started, the rock being placed in the downstream toe of the dam.

Six concrete piers were erected in the throat of the spillway, against which timber stop-logs can be set horizontally to hold the pond at any desired level. A platform or runway extends from pier to pier, and an overhead cable with traveling tackle is provided for handling the stop-logs. The floor of the spillway is paved between piers and downstream for a distance of 10 feet. A concrete cut-off wall extending into impervious solid rock, is provided at the upstream end of the spillway piers. A second concrete cut-off wall, founded on bed-rock, extends from the south abutment to the puddle core of the dam.

The total quantity of material removed from the spillway was 11,267 cubic yards, of which 10,431 cubic yards was rock, and 836 cubic yards earth.

The masonry used in the piers, cut-off walls, paving, etc., amounts to 110 yards.

The material was placed in the dam by sluicing, except the rock from the spillway cut, and the material excavated from the cut-off trench, the material not sluiced amounting to 13,985 cubic yards in all.

A gravity supply of water for sluicing was obtained from a small creek on the north slope of the valley near the dam site. A storage reservoir was built on the ridge near the headwaters of the stream in which about 1,500,000 cubic feet of water were stored, sufficient to operate the sluices for a period of 5 to 7 days, depending upon weather condition. The water was taken from the creek at a point about two miles below the storage reservoir in a 10-inch spiral wound woodstave pipe, 1,300 feet in length, discharged into a head box from which a rivetted steel slip joint hydraulic pipe No. 12 gauge, 8-inch diameter, was laid to the borrow pits, the water being delivered at the nozzles with a static head of from 150 to 200 feet.

Owing to the necessity of completing the dam in time to store water for use at the power station during the summer of 1912, and in order to preclude, as far as possible, interruptions in sluicing from failure of the gravity supply, a pumping plant was installed below the dam near the creek, and pipes laid from the pumps to the borrow pits, all arranged to permit changing from gravity to pumped supply with small loss of time. The plant consisted of two 3-stage centrifugal pumps, 6-inch discharge, capacity 1,000 gallons per minute each, driven with steam engines. Four 50-h.p. boilers were installed, and wood from the site was used for fuel. The pumping plant was put into service whenever the gravity supply ran low.

Sluicing flumes for carrying the material were erected from the borrow pits, and extended the full length of the dam. The grade of slope of the boxes was 6 per cent. on the main flumes, the size of box being 16 inches wide by 18 inches deep, built of 2-inch plank, and lined in the bottom with wood paving blocks 4 inches deep. The lateral or distributing flumes were given a grade of from 7 per cent. to 9 per cent., were not lined, and were built with lap or telescopic joints to facilitate moving.

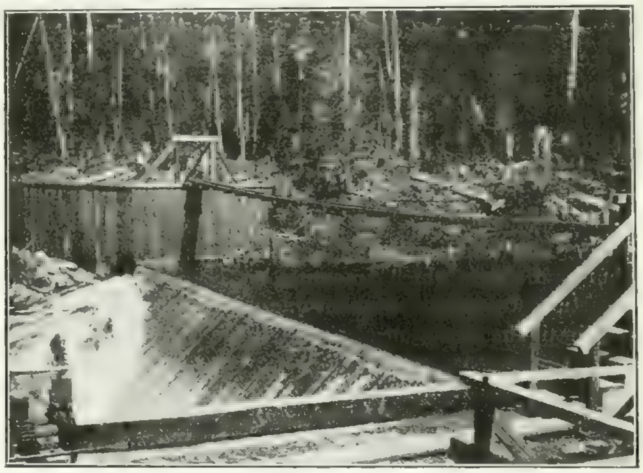
Three decks or levels of flume were used as the work progressed, the maximum height of supporting trestle being 70 feet. The trestle posts were round poles, cut on the site. The total length of flume erected for the work was:

First of lowest deck	1,050 feet
Second deck	1,150 "
Third deck	1,400 "
Lateral or distributing flumes..	3,000 "
Total	6,600 feet

About 360,000 board feet of lumber were used in the course of the entire work, the larger portion of which was in the sluicing flumes.

Sluicing was started September 1st, 1911, and carried forward night and day during the winter and spring until April 15th, 1912, when the fill was completed. More or less serious delays, due to freezing weather, snow-fall, maintaining temporary spillway through the dam for discharging flood water, and minor interruptions, were experienced; but in spite of these the average progress was better than anticipated, the estimated date of completion being May 15th.

The water in the reservoir was raised gradually as work of building the dam proceeded, no run-off being wasted after March 1st, 1912. At the date of completion the water level in the pond stood at the elevation of the spillway floor. Extremely dry weather conditions prevailed during the spring, and the basin failed to fill, the highest level reached being about 7 feet below the high-water level. The storage obtained, however—250,000,000 cubic feet—is sufficient for normal plant operation with one machine during the summer. The second unit which is being installed by the company will not be ready for service before the coming of the wet season.



Diversion Dam on the Jordan River Development.

The quantities and classification of material in the dam are:—

Excavation measurement:	
Rock from spillway and gravel cut-off trench..	13,985 cu. yds.
Material sluiced from borrow pits	129,364 cu. yds.
Total	143,349 cu. yds.
Embankment measurement, completed structure	148,390 cu. yds.
Excess of embankment over excavation measurement	5,041 cu. yds.
Excess of embankment over excavation measurement	3.6 per cent.

No attempt was made to break the hard-pan formation in the pits with the water from the monitors. Powder was used throughout the work for breaking down, holes being gophered in the base of the bank to a depth of 10 to 16 feet. A gang of men was kept constantly at work with picks, breaking up the larger masses to assist the action of the monitor stream. In fact, it was endeavored at all times to keep the solid material coming at a rate to utilize the full carrying power of the water flowing to the sluices. The quantity of water used in sluicing varied from 3 to 6 cubic feet per second, which was discharged through 3-inch and 4-inch nozzles in the pit. The following table gives a summary of the sluicing records:

Sluicing Record, Bear Creek Dam.

DATE	% time sluicing	Hours sluicing	Water used avge. in second feet	Cubic yards Placed	Proportion solids to water	Cubic yds. per 24 hrs. sluicing time
1911.						
Sept., 30 days	70 %	504	3.53	17,085	7.2%	813
Oct., 31 days	43.5%	322.8	3.2	10,300	7.3%	765
Nov., 30 days	51.9%	373	6.25	14,950	4.8%	964
Dec., 31 days	66.4%	493.5	6.25	18,150	4.4%	888
Jan., 31 days	85.6%	637	4.7	19,600	4.9%	740
Feb., 29 days	99.9%	694.5	4.3	29,650	7.5%	1110
Mar., 30 days	69.2%	518.8	3.4	17,300	4.4%	802
Apr., 15 days	48.5%	174.4	4.3	7,370	7.3%	1060
	66.9%			134,405	6.3%	893

Remarks:

October—Delay, waiting for free or gravity water.
November—Delay, waiting for free or gravity water.
Delay due to freezing weather.
December—Delay due to flood through temporary spillway.
January—Delay removing temporary spillway.
Delay due to freezing weather.
March—Delay draining fill.
April—Delay, slow work finishing crest.

A temporary spillway was maintained through the dam during the winter season, the maximum observed flood discharge through which amounted to 1,300 second feet. The structure was removed about January 1st, 1912, after which, and until the elevation of the permanent spillway was reached, an emergency overflow spillway was maintained over the dam, with plank apron attached to timbers embedded in the fill extending down the slope. The necessity of using this emergency overflow never arose. By manipulating the permanent outlet gates, the water was varied to provide storage in the main pond for floods in the stream, and the peaks were all safely passed without the water level reaching the top of the dam.

Outlet Structure.—Two 30-inch riveted steel pipes, ¼ inch thick, each 300 ft. long, are installed in the base of the dam, immediately south of the original stream bed. The trench in which the pipes are laid is excavated in the bed-rock, and backfilled with concrete which forms a casing around the pipes one foot thick on all sides. At the upper end of the pipes a reinforced concrete intake structure with screens is provided. This contains two 24-inch hydraulic gate valves with stems extended to a platform at the top of a structural steel tower 50 feet in height, from which the valves are operated. Venturi tapers were inserted in the pipes on both sides of the valves to minimize flowage losses through the 24-inch valves, made smaller than the pipe merely for sake of economy.

The excavation for the outlet works amounted to 3,730 cubic yards and 343 cubic yards of concrete was used in pipe casing and head works.

The behavior of the dam since completion has been most satisfactory. Measuring weirs set at points below the dam to intercept the water flowing by the dam, show that the aggregate discernable loss on April 4th, 1912, was .191 second feet, which was decreased on April 27th to .100 second feet. Subsequent reports indicate that the loss is steadily diminishing as the body of the fill gradually drains out.

The desirability of raising the height of this dam to obtain additional storage will no doubt appear shortly. The undertaking will be comparatively simple with the apparatus now on the site, a safe foundation installed, and all the perplexing and expensive features of design, methods, and transportation solved. By raising the embankment 20 feet the capacity of the storage basin may be increased to 608,000,000 cubic feet.

Diversion.—Two diverting dams, one in the main Jordan River, and one in "Y" Creek, a tributary stream, were installed.

Immediately below the junction of "Y" Creek with Jordan River the canyon narrows, and a ridge of outcropping bed-rock crosses the stream and extends well up the steep slopes on both sides of the canyon, forming a site well adapted for the placing of a concrete or masonry dam. It was originally planned to place the diverting dam at this point, but owing to limited time, the lack of a supply of concrete material nearer than the beach, and further, in view of the possibility of utilizing the site for the construction of a high masonry dam, which would, in addition to diverting the stream into the flume, form a large impounding reservoir in the valleys above, this site was reserved for the erection of the more permanent and higher structure at some later time, and a site for the main initial diversion was selected some 2,000 feet further up the stream.

The diverting dam on "Y" Creek was built a short distance above its junction with Jordan River, and a branch flume installed, which carries the water down the west side of the stream, crosses the main river on a timber truss 60 feet long, and discharges directly into the main flume.

The main Jordan River diverting dam is a log crib filled with rock resting throughout on solid rock. Rock from the excavation for the intake basin was used to fill the cribs. Timber cut adjacent to the site was used in the construction, the logs being notched and drift-bolted together, and thoroughly pinned to the underlying bed-rock. The top, upstream and downstream faces of the dam are sheathed with a double thickness of 2-inch plank laid with broken joints. The general dimensions of the dam are:

Length of crest	127 feet
Top width	8 feet
Upstream slope	1 to 1
Downstream slope	1 to 1
Maximum height	18 feet

Three timber head gates, with rack and pinion operating gear, are provided to regulate flow of water into the intake basin, which is also formed of log cribs, backfilled with rock, and lined with plank for water-tightness. At the lower end, and immediately above the flume entrance, sand gates are provided, depressed two feet below the flume floor, through which silt and sand collecting in the bottom of the intake basin may be discharged.

The dam has withstood the floods of two seasons, nearly 8 feet depth of water having passed over the crest at the highest stage, and at low-water the observed leakage is practically nothing. The "Y" Creek diverting dam is similar in type to the main dam already described, the crest, however, being only 90 feet in length.

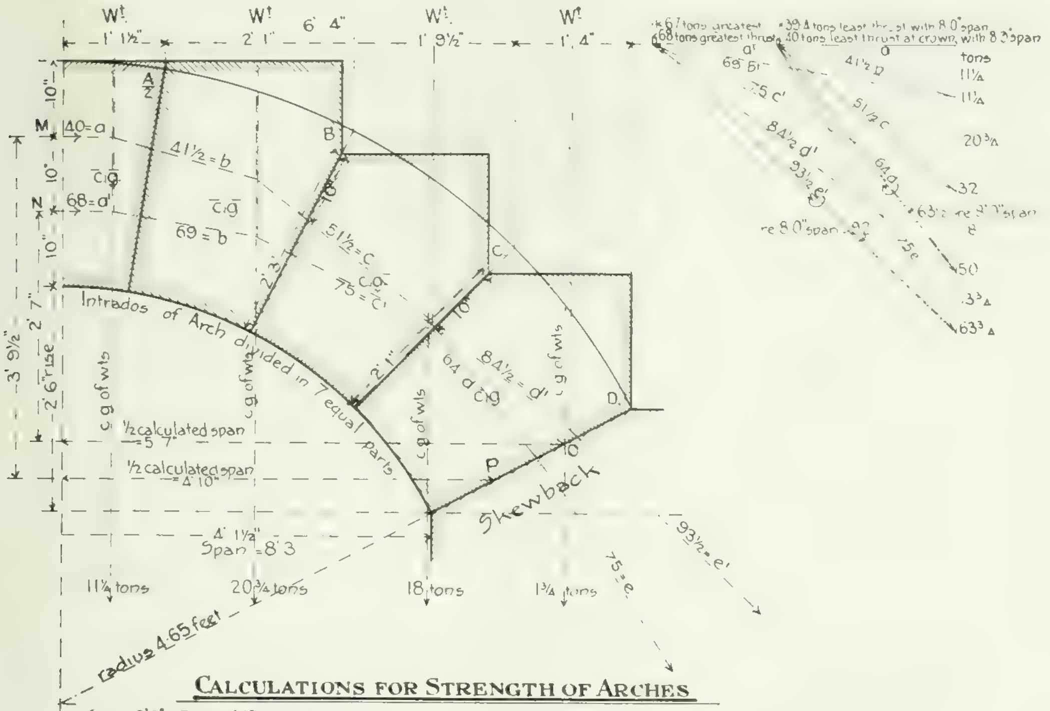
Main Flume.—The main flume follows the south side of the Jordan River canyon for a distance of about 5½ miles. The side of the canyon is precipitous at points, the slope being frequently broken with deep indentations. The formation, as a rule, is stable, and favorable for the flume foundation, consisting generally of hardpan or solid rock, topped with a comparatively thin layer of soil.

(To be continued next week).

CALCULATIONS FOR THE STRENGTH OF ARCHES.

By Leonard Goodday, C.E and M.E., late of the British Admiralty.

This paper is written with the intention of putting forward clearly a simple and practical method of obtaining the thrust on each voussoir, and finally on the skewback, with accurate results. In most cases it is taken for granted that the reader will understand the reason of each step, and, consequently, no explanation is given. The result is that too often a formula is used without the true principle or knowledge of its construction being known. The example given below was calculated for an engine-house which was built some years ago in the East.



CALCULATIONS FOR STRENGTH OF ARCHES

Span 8' 3". Rise 2' 6".
Sectional area of voussoirs 4' 6" x 2' 6" = 11 25 sq feet
Stone taken at 125 lbs per cu ft
Distributed weight, 9 3 tons per foot run
Total weight, 127 tons
Least thrust at centre $S = \frac{W \times L}{8 \times D} = \frac{127 \times 9\ 66}{8 \times 3\ 79}$ = say 40 tons
Greatest thrust at centre. $\frac{127 \times 11\ 16}{8 \times 2\ 58}$ = say 68 tons
Average thrust at centre $\frac{40 + 68}{2} \div 11\ 25 = 4{\cdot}8$ tons per sq ft
Least thrust on pier = 64 tons = 5 7 tons per sq ft
Greatest thrust on pier = $2\overline{)157\tfrac{1}{2}}$ $93\tfrac{1}{2}$ $78\ 75$ = $2\overline{)14\ 0}$ $8\ 3$ $7{\cdot}0$
Average thrust on pier = $\frac{78{\cdot}75}{11\ 25}$ = 7·00 tons

Span 8' 0"
Least thrust at centre $\frac{127 \times 9{\cdot}41}{8 \times 3\ 79}$ = 39 4 tons
Greatest " " " $\frac{127 \times 10{\cdot}91}{8 \times 2\ 58}$ = 67 tons
Average thrust at centre becomes 4 7 tons per sq ft
Average thrust on pier becomes 7 1 tons per sq ft
Allowing for deterioration and imperfections of stone
take ⅔ of the sectional area and we get
$\frac{78\ 75 \times 3}{11\ 25 \times 2} = \frac{78\ 75}{7\ 5}$ = 10 5 tons thrust per sq ft on pier
In the same way 7 2 tons thrust per sq ft at centre
For 8' 0" span, thrust at centre becomes 7 1 tons per sq ft
thrust on pier becomes 10 3 tons per sq ft

Calculations and Stress Diagram for Design of Arch.

The method given for finding the least line of resistance and thrusts on the skewback is by graphic strains, which, when drawn carefully to a large scale, is very quick and accurate, and can, of course, be checked mathematically if required. The arch had a clear span of 8' 3" with a rise of 2' 6" and 4.65' radius, and was made up of seven voussoirs of equal section for calculation, viz., 4' 6" x 2' 6". As it is necessary to have the least line of resistance within the middle third M.N.O.P. on the section, divide the arch at its centre and at the skewback into three equal parts, and obtain the spans and vertical distances as on the diagram for the calculation of the least and greatest thrusts at the centre preparatory to constructing the stress diagram. The vertical dotted lines indicate the centres of the distributed weights on each voussoir, and the centre of gravity of each stone is indicated by c. g., whilst the vertical full lines represent the centre of gravity of the total weights, including voussoirs. To obtain the least thrust at centre, the shortest span and greatest depth of the middle third should be taken, and for the greatest thrust the longest span and least depth should be taken.

It will be noticed that each thrust is lettered the same as the voussoir upon which it acts, the only difference being for the greatest thrusts which have a dash over them.

The construction of the stress diagram is as follows:—

Draw to scale the horizontal thrust a, equal to 40 tons as calculated.

From the right-hand end draw the vertical line, composed of the weights in rotation, commencing from the centre of arch.

From the left-hand end draw the lines b, c, d, e to the ends of each line representing the weights. Next, draw to scale the greatest horizontal thrust a', equal to 68 tons as calculated, and proceed as before and as shown. This completes the resolution of forces, which are built up step by step.

Beginning with the least thrust at the crown on the half section of arch, draw the horizontal thrust a from the point M until it intersects the centre line of weight through voussoir a, and from this point draw the line b parallel to the line b on the stress diagram until it intersects the centre line of weight through voussoir B, and so on to thrust d on skewback, viz., 64 tons, which equals the least thrust. For the greatest thrust at centre, viz., 68 tons, draw the horizontal thrust a' from the point N until it intersects the centre of weight through voussoir a, and continue as before to thrust e' on skewback, viz., 93½ tons, which equals the greatest thrust. From these thrusts the average thrust per square foot is obtained on the skewback and centre of arch, as shown in the calculations given below the sketch and stress diagram; and lastly, the thrust per square foot for a sectional area of two-thirds the sectional area of the voussoir, for reasons already explained.

The final results and the course of the line of resistance now obtained show that the stability of the arch is certain, and the profile of the voussoirs may be drawn out.

To do this mark off from the least line of resistance one-third of the depth, viz., 10 inches at the first and second points from the skewbacks, and construct the voussoirs, which, as will be seen, are in proper and uniform proportion to one another. The stability of an arch of this type is easier to obtain than a semi-circular one, as it is most difficult to keep the line of resistance within the middle third, an arch of this form cannot be crippled if properly constructed.

THE NEW PLANT OF THE DOMINION TAR AND CHEMICAL COMPANY, LIMITED.

The Dominion Tar and Chemical Company, Limited, has just erected a creosoting plant for the treatment of railway ties. The plant is located about six miles east of Winnipeg and is now operating. The plant has a contract to treat from 500,000 to 1,000,000 ties for the Canadian Pacific annually for ten years, which marks the first use of treated timber for ties on a large scale by that road. The plant also has a contract to treat some ties for the Canadian Northern, which will be used for experimental purposes, and large paving block contracts are being executed successfully for various cities in Western Canada.

A View of the Storage Yard for Ties.

The plant was built on a comparatively small scale, but was designed with a view to future enlargement, and some additions are now being made, while others are definitely planned. The two cylinders now being operated have a capacity of over a million ties annually upon the basis of present operations. The ties treated are principally jack pine, Norway pine, tamarack and white spruce, while some experiments are being made with British Columbia spruce and fir, and black spruce and poplar from Ontario. Although some of these species are not as well adapted to treatment as some other woods, they are used because they are easily obtainable along the company's lines. The climatic conditions in Canada are such that decay in ties is not so rapid as on roads located further south, the period of the year in which the frost is out of the ground, which is the only time that decay can seriously affect the wood being much shorter. The plant is equipped to treat timber by any method. The C.P.R. and C.N.R. contracts specify the Bethell process, injecting a minimum of two United States gallons per tie. The ties are receiving from 2 to 3½ gallons, depending upon the size of the ties. The process consists of preliminary steaming, when the timber is not air-seasoned, followed by a vacuum, after which the cylinder is filled with creosote and the desired amount of oil injected into the timber. After the oil is ejected from the cylinder, the timber is allowed to stand a short time to recover the drippings. Most of the oil used is secured from the distilling plants which the Dominion Tar and Chemical Company operates at Sault Ste. Marie, Ont., and Sydney, N.S.

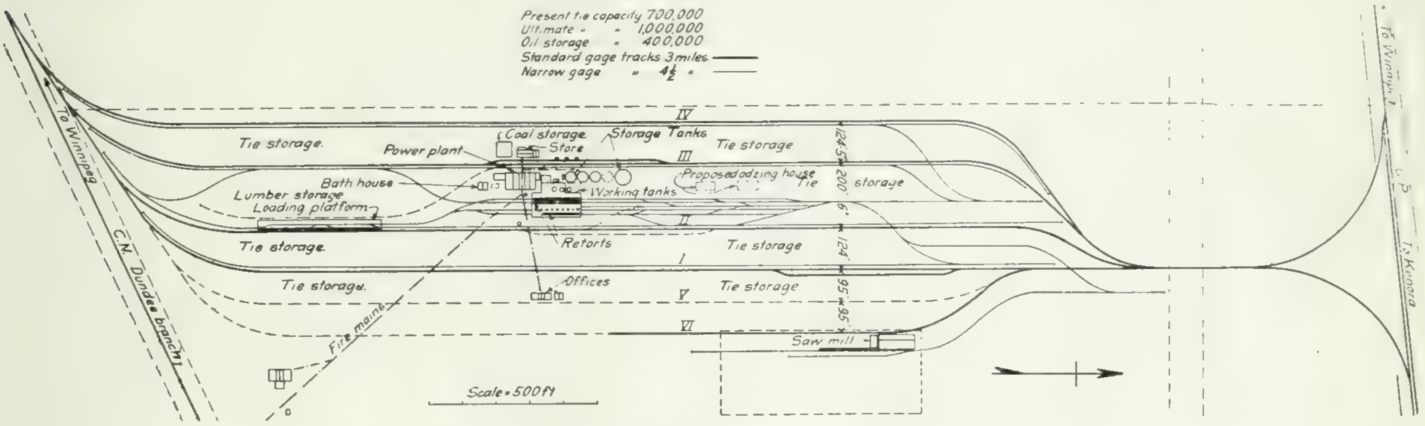
General View, Showing Treating Plant.

The treating plant occupies a tract of 40 acres, with the buildings located near one end of the yard. It is planned to add 30 acres to this next year, which can readily be done, as the company owns 110 acres. There are four long yard tracks serving the storage piles, which are designed to accommodate 700,000 ties, and the additional yard space planned for next year will provide for the stacking of over a million ties.

Practically all of the ties that reach the plant are shipped with the bark on the sides, which must be removed as the ties are unloaded. At present this work is being done by hand, but, when an adzing and boring plant is installed, as is planned for next year, it is hoped that some arrangement can be made to bark the ties by machine when they are adzed, although no detailed plan for effecting this has yet been prepared. All ties are seasoned before treatment, the length of time varying with the species of the wood and the requirements for treated material. Each yard track is paralleled by a narrow-gauge track for the operation of the cylinder cars. The narrow-gauge cars are operated by two narrow-gauge locomotives, one of which is of English make. A five-ton locomotive crane is used for handling some of the treated ties and paving block baskets and for switching standard gauge cars when necessary. It has also been found very useful in the building of tanks and other facilities about the plant. The yard is connected at one end with the main line of the Canadian Pacific and at the other with a branch line of the Canadian Northern. An elevated loading platform of frame trestle construction is provided for loading treated ties in standard gauge cars for shipment. This platform is served by two narrow-gauge tracks.

The treating plant is housed in steel frame buildings covered with corrugated iron. There are two treating cylinders 6 ft. 6 in. in diameter and 135 ft. long now in use, a third one 6 ft. 6 in. in diameter and 84 ft. long is practically completed, and a fourth one 6 ft. 6 in. in diameter and 135 ft. long has been ordered. The present cylinders have a capacity of 16 trains to a charge. The cylinder doors are swung from a crane attached to the cylinder, and when closed are secured by 24 clamps. These clamps are of heavier construction than that commonly used in creosoting plants in the United States. The cylinders are supported on I-beams carried on concrete foundations, with a special channel and I-beam construction at the expansion joints.

Two working tanks, 20 ft. in diameter and 14 ft. high, with a capacity of 34,500 gallons, supply oil to the cylinders through 8-in. pipes. A third working tank of the same size is practically completed and ready to operate. Compressed air is used to force the oil back when the pressure is removed. Recording thermometers and gauges are provided in the engine-room, which make a permanent record of the temperature and pressure in each cylinder during treatment, and a similar gauge registers the vacuum. Indicator gauges are also provided to show the amount of oil in the working tanks. The engine-room is equipped with three oil-pressure pumps, two vacuum pumps and two air compressors. The piping from the oil pumps is so arranged that either pump can force oil into either cylinder, thus eliminating the necessity for delay when either pump is out of order. Steam for the plant is supplied by two 450 horse-power Babcock and Wilcox boilers. Boiler water is secured from wells, and is treated by a soda and lime softening process. The boiler feed water is heated by a Cochrane heater. A 350-amp. 100-volt generator direct connected to a 50 horse-power engine furnishes electricity for 16 arc lamps and 350 incandescent lamps throughout the yard and the buildings.



Plan of Layout of Creosoting Plant.

A machine shop alongside the boiler plant is able to take care of minor repairs, and the locomotive house adjacent to the machine shop is used to store the yard locomotives. A bath-house is provided in the yard for the use of the 135 or more workmen which the plant employs. This house is equipped with two showers and four tubs. A boarding-house is furnished by the company near the yard for the accommodation of the workmen. The supply of creosote for the plant is kept in three storage tanks at present, one 40 ft. in diameter and 25 ft. high, and two 30 ft. in diameter and 15 ft. high. Two additional 30-ft. tanks 15 ft. high have been ordered and will be erected this year.

Mr. E. Bernard Smith, the general manager of the Dominion Tar and Chemical Company has recently removed his office, which is the head office of the company, from Sault St. Marie to the new Birks Building, Montreal.

The plant is operated under the direction of F. W. Zoates, manager for the Dominion Tar and Chemical Company, and G. G. Roberts, assistant manager. J. H. Dixon is the representative of the Canadian Pacific at the plant.

THE TREATMENT OF SEWAGE SLUDGE.

One of the largest schemes for the treatment of sewage, entailing an expenditure of $6,000,000, is now being carried out by the corporation of Bradford, England. The original works at Frizinghall having proved to be inadequate, an estate at Esholt, covering an area of 1,856 acres, was purchased in 1906, situated to the northeast of the city, and about six miles distant from the centre of the town.

The plant for dealing with the sludge has been removed from the old works at Frizinghall and housed in new and commodious buildings at Esholt; and since it has been found necessary to retain for the time being the old precipitation tanks at Frizinghall for the collection of the sludge, a temporary 8-in. steel pipe-line has been laid down, some five miles long, to deliver sludge to the new works. The main which follows the towpath of the Bradford and Leeds and Liverpool Canals has been laid in such a manner that it has sometimes a falling gradient and sometimes a rising gradient, whilst a great length of it is level. The total fall from the inlet to the outlet end is 70 ft. In order to get sufficient velocity to discharge 500 tons of thick sludge, containing only 80 per cent. of water, compressed air is fed into the main with the sludge, and this is the Pohle air lift worked upside down. It is found that the pressure on the inlet end varies from 30 lb. to 40 lb. per sq. in. The sludge is fed into the main by compressed-air-operated sludge-rams.

The new buildings, which cover 1¼ acres, are faced with a coarse sandstone. The design is in keeping with the nature of the stone, being massive and rugged in appearance, and the moulds simple, but bold.

In addition to the boiler-house, engine-house, and water-tower there is a press-house measuring 237 ft. by 92 ft., which contains 128 sludge-presses—64 of which have been made by Messrs. Manlove, Alliott and Co., Limited, of Nottingham; 36 by Messrs. John Wilson and Sons (Johnstone), Limited, of Johnstone; and 28 are now being made by Messrs. Knowles and Co., of Bradford, to complete the installation of 128. The grease-house, measuring 237 ft. by 50 ft., contains 16 grease-vats, each capable of purifying 6 tons of grease, with a grease storage tank under, capable of holding 1,000 tons; also grease separators, sludge-boiling vats, and rams.

The sewage of Bradford presents unique features on account of its strength, character, and concentrated condition, for which the trade refuse discharged into the sewers is responsible, and on account of this peculiar character the sludge-disposal works present novel features, being designed for the recovery of grease from the sludge. The method adopted by Mr. Garfield, the engineer of the scheme, is as follows: The sludge, on its arrival at the receiving-tanks, is lifted to the boiling-up vats by means of compressed air, here it is heated by live steam, and passed into three steel vessels placed underneath, and from which it is forced by compressed air to the sludge-filter presses. Each press contains forty-seven chambers, 3 ft. square. The object of heating the sludge is to facilitate the filter pressing, and to render liquid the grease contained in the sludge. The grease and water coming away from the filter-presses are separated in tanks, from which the water is pumped back again into the sewage, and the grease into the purification-vats.

From these vats the grease is run into barrels, pumped into tank-wagons on the adjoining railroad, or discharged into the storage-vats, whichever may be necessary. It has been found that the 100 filter presses now in operation produce from 12 to 15 tons of grease per twenty-four hours, which is valued at from 8l. to 10l. per ton, and the resulting cake is more valuable than that usually produced, consequent upon the fact that it contains no lime and only 28 to 30 per cent. of moisture. It is sold at the price of 3s. per ton at the works, where it is loaded direct from the filter-presses into the railway-wagons below.

Two main sewers eventually will convey the sewage of Bradford to Esholt. The larger sewer will be 10 ft. in diameter with a gradient of 1 in 2,000, and be capable of discharging 180 million gallons of sewage daily. This sewer will be in tunnel for 4,807 yards, and the work is about to be commenced. The smaller sewer has been completed, the contractors being Messrs. H. Arnold and Sons, of Doncaster. This sewer intercepts the sewage of Eccleshill and Idle, and conveys it to the works by gravitation, the cross-section being egg-shaped in form, 3 ft. 6 in. by 2 ft. 4 in., 1 mile in length (one-third of which is in tunnel) with a gradient of 1 in 630, and capable of discharging 12 million gallons of sewage. Into this sewer will be pumped the low-lying area of Greengates, where a pumping station with two 6-in. centrifugal pumps of the "Stereophagus" type is now being erected. These pumps will be electrically driven and automatically controlled, and have been designed to pass unscreened sewage. They are capable of raising 2,000,000 gallons of sewage and trade effluent through a 12-in. rising main to a height of 100 ft. daily. Tanks have been provided at the works to treat temporarily the sewage of these districts and of the district of Yeadon by chemical precipitation, the effluent being finally purified by land filtration.

The engineer of the scheme is Mr. Joseph Garfield, Assoc.M.Inst.C.E. For the 10-ft. diameter sewer and Aire Valley Crossing the engineers are Messrs. James Watson, M.Inst.C.E., and Joseph Garfield, Assoc.M.Inst.C.E., acting jointly; whilst the resident engineer is Mr. Howard Wontner-Smith, Assoc.M.Inst.C.E.

◆

TRAIL LOCATION AND CONSTRUCTION.

In a paper published in the Forest Club Annual of the University of Nebraska, Mr. Ernest Wohlenberg gives an interesting discussion on trail location and construction. He states that the first and most important consideration in trail construction is always the location, and grade is the determining factor in location. Where it is steep, switchbacks should be resorted to. The methods used in location are: (1) Compass and Abney hand level (accurate); (2) hand level only (fairly accurate), and (3) ocular levelling (inaccurate).

A route should first be reconnoitered and definitely decided upon before it is staked out. The main points can be sketched in on a map by means of a compass and hand level. On short distances the hand level will be sufficient. Laying out by eye is a poor method and inaccurate at its best. The route should be staked every 50 to 100 ft. and blazed, but as a usual thing routes are laid out by blazing only. The blazes should be made close together along the trail so that there will never be any trouble in following them. Location should always be from the top of a hill to the bottom, otherwise the maximum grade is apt to be exceeded, because in locating from the bottom there is danger of making the grade steeper than necessary. Location work can be done with a crew of three men and costs from $2 to $10 per mile.

There are several choices for trail routes: (1), Valley or canon; (2), ridge route; (3), trails crossing mountains, and (4), foothill. The use of one of the first two routes depends somewhat on the nature of the country. Where the canons are extremely steep, narrow, and full of boxes or interrupted by cliffs, the ridges and sidehills can be followed without much trouble. For the latter, the south sidehills should be used, because they are passable three weeks earlier in spring and later in autumn than north hillsides. Where the country has been worn down the valleys have a gentle grade and are fairly wide, so that they make good trail routes. Routes crossing the mountains are usually expensive and contain steep grades. Foothill routes are undesirable because there is so much winding in and out of the heads of canons, to keep an even grade, that the trail becomes extremely long.

Factors which influence the building and cost of trails are: (1), Grade; (2), width of the cleared space and the tread; (3), nature of soil; (4), cost of labor; (5), distance for packing supplies; (6), distance men have to walk to the work; (7), cost of supplies; (8), supervision. Grade is the determining factor.

The cleared space varies from 6 to 14 ft., and the tread from 1 to 4. ft. Ordinarily a tread of 18 in. is wide enough, for a horse will almost invariably travel on the lower side of a trail and always in the same place; if the trail is wider, the inside will fill up with sliding material and the extra cost in excavation will be thrown away. On turns, trails are widened and on switchbacks the width is doubled. The trail bed should be flat. Excavation should be made into the bank instead of building up the outer side of the trail, because on steep slopes earth thrown out of the trail makes a poor footing. The supervision of the crew is a most important factor, for if the work is not arranged as it should be, the trail will be expensive under the most favorable conditions.

The size of the crews varies from 2 to 15 men. In crews of 8 to 15 men it is necessary to have a cook, a packer, and a foreman. The brushing out can be done by 2 to 4 men, while 5 to 8 can do the grading. Small crews vary from 2 to 5 men.

On side-hill locations where water will run down a trail, it is always best to put in water bars; that is, small ditches 2 to 4 in. deep, running diagonally across the trail and banked on the lower side with earth or a small log sunk a few inches in the ground. These will turn the water and prevent any great amount of washing, which might ruin a trail. The number of water bars will vary with the grade of the trail and the degree of slope of the side hill. It is much cheaper to put them in when building the trail than afterward. Under ordinary conditions they can be located from 150 to 225 ft. apart. In building a trail, the country should first be reconnoitered and the route fully decided upon. It should then be located by stakes or blazes, and cleared and brushed, after which it will be graded and the tread formed to the specified width.

A NEW TYPE OF WATER TURBINE CHAMBER.

At low-head developments it is a common occurrence that during periods of floods the tail race water level raises to a considerable height and the endeavor of the designers of water turbine plants has been to place the electrical machinery and the power house floor above the highest tail water level experienced. In order to accomplish this use has been made of the arrangement with vertical shaft, whereby it is possible to place the generator at any height above the water level by only lengthening the shaft. However, this arrangement with vertical shaft has various well-known drawbacks as the accessibility of the turbine suffers greatly, and the dismantling of same is very complicated and requires a long time. The desirability of being able to install at low heads, as above described, horizontally arranged water turbines led the firm of Escher Wyss & Company to the design of a turbine chamber with artificially raised head water level.

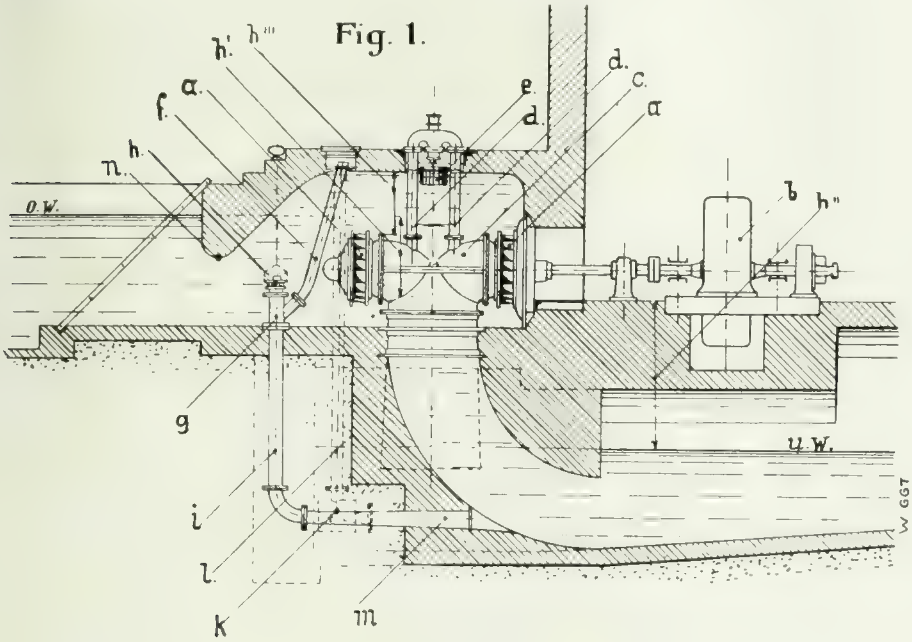


Fig. 1.

In order to ensure proper working of water turbines installed in open water chamber, it is necessary that the turbine be submerged to a certain extent so as to prevent any air from entering the machine, whereby the efficiency and the power would be decreased considerably.

The above mentioned arrangement, with artificially raised water level enables the designer to place the upper edge of the turbine (no matter if the shaft is arranged horizontally or vertically) slightly below the head water level. The advantages of thus placing the machine as much elevated above the tail water (of course within the possibility of proper suction) is: Firstly, that the direct coupled generator may be located considerably higher above tail water level than previously was possible, and secondly, that the excavation required for the tail race canal, and consequently the expense is reduced to a great extent. It goes without saying that the same advantage is gained if the turbine is of the vertical or horizontal type.

This method of artificially raising the head water level is of late very often adopted, and in special cases with the greatest advantage. The patent for this arrangement has been taken out by Escher Wyss & Company in most countries, and the demand for this kind of installations has increased very rapidly, so that quite a number of plants of this type are in operation at the present time. The raising of the head water level may be effected in different ways. Reference is directed to the illustrations, Figs. 1 and 2. There will be observed that the wheel pit is covered by a concrete roof, which is made air-tight. By sucking the air which remains between the head water level and the concrete roof the water level is raised gradually until the whole wheel pit is completely filled with water.

There are two different methods of obtaining this. The first method works automatically in the following way: As soon as the turbines open the water discharges through same and sucks through the pipes "D" attached to the draft chest, the air, thereby gradually the water (of course within the possibility of whole chamber is filled. As soon as the chamber is full an automatic float valve closes the pipes "D" so that no more water is discharged through the draft chest and consequently very little water is actually wasted. The other method consists of a separate connection between the water chamber and the draft tube, which is opened by hand, and discharges the water through same continuously during the operation of the turbine. In consequence, this quantity of water is wasted.

With the first method the turbine has to be put in operation before the wheel chamber is being filled and the level raised. With the second method the wheel chamber might be filled and the head water level raised before the turbines are opened and put in operation. Fig. 2 depicts a similar arrangement adapted to a vertical turbine installation.

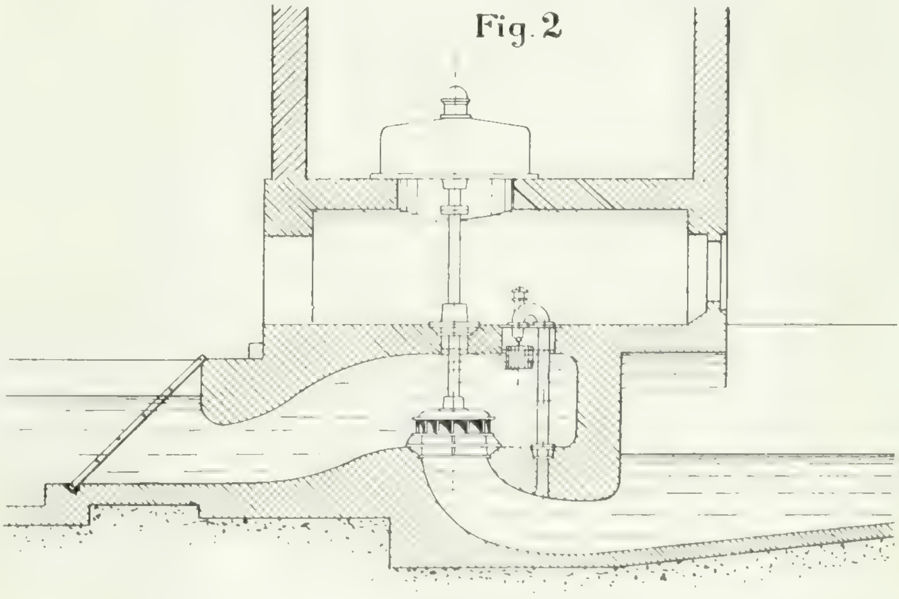

Fig. 2

Fig. 3 shows a cross section of such a water chamber with the turbine units erected. The automatic air sucking off devices with float valves are shown in the upper vaults on each side of the inspection shaft, in the centre of the chamber. The three first turbines working with this patent are in operation in Unterbruck, Bavaria, for the Amperwerke Electric Works, Munich, and were started up in 1908 and have been working with entire satisfaction since. The Unterbruck installation contains three turbines each with four runners having an output of 650 h.p. at a head of 15½ feet.

Since that time Messrs. Escher Wyss & Company have constructed a great many turbines working with artificially raised water level, of which the following are the most important:

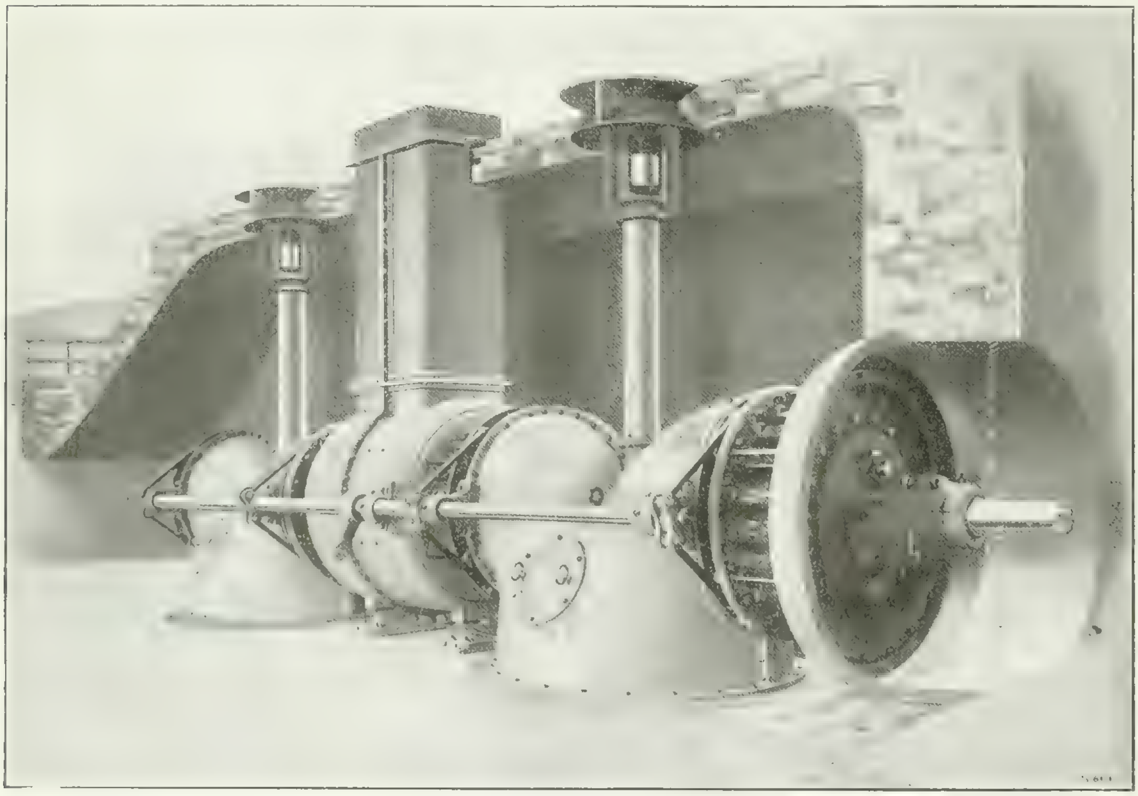

Fig. 3.

Messrs. Jenny & Schindler, Kennelbach-Tirol, in 1910, one turbine of 250 h.p. working under a head of 10½ feet. This turbine has four runner wheels on one shaft.

Societe Union Electrique de St. Claude (France), in 1909, two turbines, each of 945 h.p. and working under a head of 23 feet, for the Saut Mortier installation. In 1912 a repeat order was given for a third unit for the above installation and the capacity being increased to 2,200 h.p. under a head of 36 feet.

Messrs. Calvet, of Barcelona (Spain), in 1911, one 240 h.p. turbine with horizontal shaft working under a head of 11 feet.

The air may also be extracted by means of a jet-pump, which has induced Messrs. Escher Wyss & Company to take up the construction of turbines which can be erected above the head race water level. In order to start the machine an artificial water level must be created by operating the jet-pump, as shown in Fig. 1.

A turbine of this type fitted with six runner wheels on one shaft is at present in course of construction, destined for Messrs. Guenther & Richter, of Wernsdorf, Germany. This turbine has an output of 1,730 h.p. when working under a head of 16¼ feet.

NEW CARS FOR LONDON COMPANY.

The London & Lake Erie Railway & Transportation Company, of London, Ont., recently received from the Niles Car and Manufacturing Company two motor passenger car bodies and two trailer car bodies. These cars are of light weight, the body weighing about 21,000 lbs., and will seat 54 persons. They are built for double end operation. The arch roof and single side walls decrease the weight and cost, and increase the width of aisle and length of seats. The cars are designed to handle summer excursion traffic.

The general dimensions of the cars are as follows: Length over buffers, 49 ft. 4 ins.; length of car body, 38 ft.; length of passenger compartment, 27 ft 2 ins.; length of smoking compartment, 10 ft. 10 ins.; width over all, 8 ft. 8½ ins.; height under sills to top of roof, 9 ft.; height from track to top of roof, 11 ft. 10 ins.; distance between bolster trucks, 26 ft.; wheel base of trucks, 6 ft. 4 ins.; length of seats, 36 ins.; width of aisle, 26½ ins.

The underframe is of semi-steel with two centre sills of 6-in. steel I-beams reinforced on both sides under the platforms with ½-in. by 5-in. steel plates; two side sills of ⅝-in. by 7¾-in. steel plates between yellow pine sills; two 9-in. plate truss bolsters; two 6-in. I-needle beams; two 4-in. by 3-in. end sill angles; two ⅝-in. buffer plates; ¾-in. tie rod at each cross joist; and two 1¼-in. under-truss rods, and wooden framing. The floor is of double thickness yellow pine with waterproof tar felt between. The alternate panel and single side posts of the body are of oak with ½-in. vertical rods; single wall below windows of 1-in. tongue and groove oak gained ¼ in. over each post, finished inside for waist panel and sheathed outside with ¾-in. by 2-in. vertical poplar. The vestibules are flush with the car floor, and supported on steel centre sills. The car has 36-in. folding doors and has double steps and trap door over the opening at each side. In the trailers the body end bulkheads are omitted and iron pipe railings are placed between the step openings and the corner seats. The roof is of single arch style with concealed steel rafters. The interior finish is of oak. The ceiling is fitted with roof boards and rafters. The car trimmings are of bronze. A toilet is located in the main compartment against the smoking partition and has a dry hopper, sanitary finished and a cement floor. A water cooler is located in the alcove on the outside. The cars are fitted with 14 square-corner twin windows on each side, having stationary upper sashes, with five sections of clear glass in zinc channels so standing passengers can see out. There are three windows across the ends of the car, affording passengers an unobstructed view in either direction.

The motor cars are equipped with four Westinghouse, No. 93A, 60-h.p., 600-volt, d.c. motors, straight air brakes and Baldwin trucks. They weigh complete about 28 tons.

◆

ASTRONOMICAL OBSERVATIONS FOR AZIMUTH ON DOMINION LAND SURVEYS.

By J. A. Macdonald.*

With the high class of instruments now supplied our Dominion land surveyors, Azimuth observations, by using Polaris, are possible at almost any time on a light, clear, day, provided the telescope is properly focused. During the summer difficulties are sometimes experienced in detecting the star, when the object glass is not sufficiently protected from the reflection of the sun's rays. The instrument makers, however, provide a ray shade to obviate this.

On every clear day the watch error is easily determined by the surveyor by the sun's transit at noon. This observation entails no delay, and is by far the safest, because an observation on a star for the same purpose might keep the surveyor late on the line, but often prove impossible later on in the day.

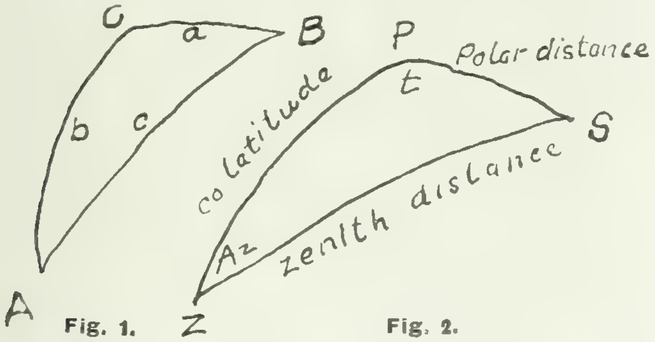

Fig. 1. **Fig. 2.**

The formula recommended by the Surveyor-General's Department for the reduction of Azimuth observations in Polaris is derived as follows:

In the spherical triangle to be solved, two sides and the included angle are given. The sides are arcs equal to the co-latitude of the place of observation, and to the Polar distance of the star (Polaris).

They include the hour angle of this star at the moment of observation.

The required angle and Azimuth of Polaris is formed by the two great circles which intersect at the zenith, and of which one is the Meridian of the place.

In Fig. 1.—To prove $\tan A = \dfrac{\tan a \operatorname{cosec} b \sin c}{1 - \tan a \cot b \cos C}$

$$\text{Now, } \frac{\sin A}{\sin a} = \frac{\sin C}{\sin c} \text{ or } \sin A \sin c = \sin C \sin a \quad (1)$$

and $\cos a = \cos b \cos c + \sin b \sin c \cos A$,

$$\text{or, } \sin c \cos A = \frac{\cos a - \cos b \cos c}{\sin b} \quad (2)$$

Dividing (1) by (2) we get

$$\tan A = \frac{\sin a \sin b \sin C}{\cos a - \cos b \cos c}$$

Dividing numerator and denominator by $\cos a \sin^2 b$ we get

$$\tan A = \frac{\tan a \operatorname{cosec} b \sin C}{\dfrac{1}{\sin^2 b} - \dfrac{\cos b \cos c}{\cos a \sin^2 b}}$$

Now, $\cos c = \cos a \cos b + \sin a \sin b \cos C$

Hence,

$$\tan A = \frac{\tan a \operatorname{cosec} b \sin C}{\dfrac{1}{\sin^2 b} - \dfrac{\cos b}{\cos a \sin^2 b}\left(\cos a \cos b + \sin a \sin b\right.}$$

$$= \frac{\tan a \operatorname{cosec} b \sin C}{\dfrac{1}{\sin^2 b} - \dfrac{\cos a \cos^2 b}{\cos a \sin^2 b}} - \frac{\sin a \sin b \cos b \cos C}{\cos a \sin^2 b} =$$

$$= \frac{\tan a \operatorname{cosec} b \sin C}{\dfrac{1}{\sin^2 b} - \dfrac{\cos a \cos^2 b}{\cos a \sin^2 b} - \dfrac{\sin a \sin b \cos b \cos C}{\cos a \sin^2 b}}$$

$$= \frac{\tan a \operatorname{cosec} b \sin C}{\dfrac{1 - \cos^2 b}{\sin^2 b} \quad \tan a \cot b \cos C}$$

$$= \frac{\tan a \operatorname{cosec} b \sin C}{1 - \tan a \cot b \cos C}, \text{ since } 1 - \cos^2 b = \sin^2 b$$

Now in the spherical triangle P Z S (Fig. 2).

P = Pole

Z = Zenith

S = Star (Polaris)

$$\tan PZS = \frac{\tan PS \operatorname{cosec} PZ \sin ZPS}{1 - \tan PS \cot PZ \cos ZPS}$$

$$\text{or } \tan \text{Azimuth} = \frac{\tan P \sec L \sin t}{1 - \tan P \tan L \cos t}$$

where P, L and t are Polar distance, latitude and hour angle respectively.

This is the formula recommended by the manual of surveys of Dominion lands for the reduction of Azimuth observations by using Polaris, though its derivation is not shown in the manual, but it is here given in graphic form.

Surveyors are, however, at liberty to use any formula or process for reducing their observations, but as forms and tables could not be prepared for every method this formula,

$$\tan Z = \frac{\tan P. \sec L. \sin t}{1 - \tan P. \tan L. \cos t}$$

where Z. P. L. t. are Azimuth, Polar distance, latitude and hour angle respectively.

The logarithms of secant and tangent L are given in tables for the north side of every section

By means of these astronomical field tables now supplied surveyors, the observation has become very easy and simple.

The instruments necessary are a watch, keeping sidereal time, that is to say, gaining 3 minutes 56 seconds a day, and a four-inch transit theodolite, now listed by several manufacturers, so-called "Canadian Pattern." A common watch of a reputable manufacturer is good enough. The best grades keep the time for weeks and months with sufficient accuracy, the error being ascertained from time to time by a Meridian observation of the sun or star.

---

* Of the Topographical Surveys Branch, Department of the Interior, Ottawa.

In the western provinces and territories the air is exceedingly transparent, and a light, star-like Sirius may be seen at any time during the day. The pole star is best seen about an hour to a half hour before dark. While there is still ample light for reading the graduation, it may also be observed in the morning.

Observation of the Pole Star for Azimuth.

The instrument must be carefully levelled. The observation is made on a section line or traverse station, which is called the reference line, the bearing of which is known with sufficient approximation for setting the instrument in the Meridian.

Set the vernier of the horizontal circle to read the bearing of the reference line, loosen the lower clamp and turn the instrument until the telescope is directed on the reference line; fasten the lower clamp and release the upper clamp. The instrument is now set to read the astronomical bearings. By setting the vernier at 360 deg., the telescope is in the Meridian.

In the example below, the vernier is set to read 180° 05′, the lower clamp released and the telescope directed on the east boundary of section 18. The telescope is set for the latitude of the pole star, shown in tables furnished the surveyor. For example, in the example the table or diagram shows a latitude of 51° 20′ corresponding to township 27. The vernier is now set to read the bearing of the star taken from the time shown by the watch. In the example it is set at 358° 19′. So set, the star is in the field, and will be seen, provided the telescope is accurately focused. The time by the watch is noted as well as the horizontal circle reading. For all Azimuth work it is essential that the observation be made in two positions of the instrument, circle right and circle left. The position of the instrument is reversed by transmitting the telescope and turning the vernier plate 180°. The first part of the observation is now repeated. The H. C. R. on the reference line is recorded, the telescope is set at the altitude of the star, the vernier at the bearing, and the field is scanned for the star. When found, the time by the watch and horizontal circle reading are again recorded.

The following example shows clearly how the observation is worked out:

Astronomical Observation.

Date—January 19, 19—, 8.45 a.m., mountain time.
Place—N.E. corner Sec. 18, Tp. 27, R. 20, W. 3rd. Mer.
Reference Line—East boundary of Sec. 18.

	Face.	H.C.R. on reference line.	H.C.R. on Polaris.		Watch time.
1	Right	180° 05′	1° 21′.9		16 h. 22 m. 57 s.
2	Left	180° 03′	1° 23′.0		16 h. 25 m. 07 s.
	Mean	180° 04′	1° 22′.45		16 h. 24 m. 02 s.
3	Watch correction			——	42 s.
	Sidereal time				16 h. 23 m. 20 s.
4	Tabular bearing for 16 h. 20 m. and Tp. 20				1° 15′.5
5	Difference for 3 m. 20 s.			+	1′.1
6	Difference for 7 townships			+	1′.0
7	Convergence for 2 sections			+	2′.2
8	Bearing of Polaris				1 19′.8
9	H.C.R. on Polaris				1 22′.45
10	Correction to H. C. R.			----	2′.65
11	H. C. R. on reference line				180° 04′
12	Bearing of reference line				180° 01′.35

The bearing is generally found to differ from the bearing by account which was 180° 05′ in this example. The difference represents the accumulated errors of the survey. It is distributed among the previous courses of the survey, according to the judgment of the surveyor.

In the observation, the watch correction was assumed to be known within one minute. This correction has to be ascertained from time to time, more or less frequently according as the watch is of a better or of an inferior grade.

The watch having been set approximately to sidereal time, its correction is ascertained by observing the meridian transit of a star or of the sun.

When it is desired to observe at a place where no line of known bearing exists, the surveyor sets his instrument in the Meridian by means of the compass for turning the instrument in the direction of the star. The magnitive declination can now be easily determined from tables, when the star can be brought into the field of the telescope.

◆

COAL IN THE WEST INDIES.

The only locality in the West Indies where coal has been found is the island of Trinidad. There is little information as to its mode of occurrence and extent, for attention has been mainly directed to the investigation of the deposits of petroleum and its residual deposits of bitumen, including asphalt and "manjak."

A seam of lignite (brown coal) from 4 to 6 ft. thick is said to occur in the cliffs of the south coast between Oropuchy and Moruga, in strata of Tertiary age dipping to the east at an angle of 30°. It sometimes contains interlaminar deposits of calcium sulphate, and is frequently discolored by the presence of iron oxide. In other cases it is more compact, and resembles cannel coal or pitch, being evidently allied to "manjak." An analysis of a mixed sample in the Scientific and Technical Department of the Imperial Institute gave the following results:

	Per cent.
Volatile matter (including sulphur but not water)	32.9
Fixed carbon	34.0
Water	13.7
Ash	19.4
Sulphur	5.06
Calorific value,[1] small calories	4,378
Evaporative power[2]	8.17

[1] The calorific value represents the number of grams of water raised from 0° to 1° C. by the combustion of 1 gram of the coal.

[2] The evaporative power represents the number of grams of water at 100° C. converted into steam at the same temperature by the combustion of 1 gram of the coal.

The coal burned readily with a highly luminous flame. When it was heated to drive off the volatile constituents, the residue did not cake and form coke, but left a friable mass which fell almost at once to powder. The coal is therefore of inferior quality, the percentage of fixed carbon being too low, and that of ash and sulphur too high. The amount of sulphur is no doubt largely due to the presence of calcium sulphate, which might be removed by washing. The fact that the samples were taken from the surface may be responsible for their poor quality.

THE JORDAN RIVER DEVELOPMENT OF THE VANCOUVER ISLAND POWER COMPANY.

The Jordan River Development of the Vancouver Island Power Company, Limited, is an exceedingly interesting one from many points of view. The plant itself is not a very large one, but the difficulties that were met with and overcome in securing the necessary data, and afterwards, in installing the plant, were exceptional.

The preliminary investigations were carried on in what was practically virgin forest, and the engineers had practically no data to hand to enable them to decide where the development should be located. The powerhouse itself is located in almost inaccessible country, and the difficulties of getting a construction plant on the ground, together with the actual construction of the plant, will, therefore, be appreciated. The first section of a description of the Jordan River Development appears in this issue of *The Canadian Engineer.* The way the necessary data was compiled, and the constructive details were worked out, reads most interestingly. The engineers in charge of this work are to be congratulated for the ingenuity and perseverance shown throughout the investigation and the actual construction.

◆

THE INTERNATIONAL JOINT COMMISSION AND SEWAGE POLLUTION OF BOUNDARY WATERS.

As has been noted in these columns from time to time, the International Joint Commission is taking up, under instructions from the several governments, an enquiry into the pollution of international boundary waters. At the Washington session on November 18th, Secretary of State Knox directed that, "The enquiry should be confined to cases of pollution on one side of the boundary which extend to and affect the other side." This statement very much limits what was thought to be the original scope of the enquiry. It would appear from this statement that investigation of pollution would be restricted to the narrow waters of the St. Mary's River, Mackinac Strait, the St. Clair, Detroit, Niagara and St. Lawrence Rivers. Thus, the cities of the United States, which are located on the Great Lakes, and which are at present polluting lake waters, do not come within the sphere of investigation of the Commission.

It would appear that the above limited meaning of what is meant by sewage pollution will greatly impair the usefulness of the investigation. This construction is placed on the enquiry by the United States Branch of the International Joint Commission. It is not believed, however, that the Canadian Branch will assent to the above meaning. While it is true that it is highly desirable to investigate the relationship of cities, such as Buffalo and Detroit, to the question of sewage pollution, it is just as desirable that cities like Rochester and Cleveland should also come within the meaning of the enquiry.

If this investigation is to serve the best interests of Canada and the United States, it is highly desirable that the scope should be understood to include all cities and municipalities using international waters as a means of sewage disposal. With the limited construction placed upon the question, it would be impossible for the Commission to consider pollution of international boundary waters from boat traffic, and this would be a serious limitation.

EDITORIAL COMMENT.

The council of a thriving Western municipality announce that they will erect a jail and storehouse in one building at a cost of $20,000, but omit to state what preparation has been made to preserve the "long termers" during the storage period.

* * * *

The executive of the Ontario Good Roads Association announce that the annual meeting will be held on February 26th, 27th and 28th, in the Machinery Hall of the Toronto Exhibition grounds. A Good Roads exhibit, showing different classes of road-making machinery and samples of various roadbeds, will be held at the same time. This exhibit should be an added stimulus to this already very successful Association. No doubt, the different manufacturers will be interested in making the exhibit a success.

* * * *

In this issue, under "Letters to the Editor," will be found certain correspondence in connection with an editorial which appeared in our issue of November 7th on "Protection of Canal Lock Gates." Our impression was, at the time this editorial was written, that the Gowan Safety Device had been in use on gates other than Lock 24 of the Welland Canal. We are glad to note Mr. Gowan's correction. The letter from Mr. W. H. Sullivan, Superintending Engineer of the Welland Canal, corroborates Mr. Gowan's statement that the gates at Lock 24 have had some severe tests.

* * * *

In our last issue, November 21st, the City Commissioners of Edmonton advertised for sealed tenders for "Paving for 1913" for approximately 400,000 square yards of asphalt and bitulithic pavement. The Commissioners of Edmonton cannot be too highly congratulated for their progressiveness in this matter. The only sure way of getting a paving contract started early in the spring is to call for tenders in the preceding fall. Far too often paving work is just being started in September or October, with the result that the pavements are always at least a year behind. If more city engineers would follow the move of the City Commissioners of Edmonton there would be less trouble in the letting of contracts for the summer's pavements, the work would be better done, and it would be finished on time.

LETTERS TO THE EDITOR.

PROTECTION OF CANAL LOCK GATES.

Sir,—Your article in last week's issue of The Engineer re "Protection of Canal Lock Gates," is timely and appropriate, as far as the necessity for the adoption of some efficient device for the protection of lock gates against the impact of vessels is concerned.

In this article you describe the "Gowan safety device" and the "chain fender system," the former as applied on the Welland Canal, the latter to be on the Panama. While you admit the Gowan safety device has been very successful on the Welland in cases of small speed, you conclude that, from the number of accidents recently occurring, some more suitable device is necessary, and suggest the "chain fender," as to be applied on the Panama.

Admitting that the intention of your article is to be fair to both devices and in the interests of navigation, the writer must take exception to your conclusion, as it is based on a wrong idea, viz., that the gates on the Welland Canal are equipped with the Gowan safety device. This is not so.

In the description of the Gowan safety device, supplied you by Mr. J. L. Weller, now engineer-in-charge of the new Welland Ship Canal, and appearing in your issue of July 4th, 1912, the words, "as applied to the existing gates of the Welland Canal," are incorrect, and may have misled you. This device has, so far, been installed on one lock only on the Welland, viz., Lock 24, one of the most dangerous points on the canal, and has proved by three actual tests to be a decided success, not only against a light impact, as you describe, but against a vessel under full steam, as in the case of the "Harry Packer," which snapped three cables and cut an oak wale on the gate, 6 x 10, completely in two with her stem. Had the Welland Canal lock gates been equipped fully with the "Gowan safety device," the accidents you record would have in no case happened, and your article in reference would have been uncalled for.

The Engineer can get full corroboration of the above statements as to the merits of this device under actual tests from the Department of Railways and Canals, Ottawa, or by applying to W. H. Sullivan, Engineer-in-Charge, Welland Canal, St. Catharines, Ont.

It is hoped you will give this letter as full publicity as your article, to which it is a reply, said article having been copied by other papers.

Yours respectfully,
N. W. Gowan,
Inventor and patentee.

St. Catharines, Nov. 16th. 1912.

Sir,—Replying to your communication of the 19th inst., I would state that the Gowan safety device for the protection of lock gates was installed by Mr. Weller, now Engineer-in-Charge of Welland Ship Canal, on the upper gates of Lock No. 24 of the Welland Canal about two years ago.

This lock was chosen on account of its being the one where the consequences of a break would prove most serious. Until the present season no vessel collided with these gates with sufficient force to give the device a severe test.

On May 20th, 1912, the steamer "Beaverton," bound up, while locking, surged ahead with sufficient force to break a wire hawser, striking the upper gates and opening them sufficiently to admit the boat's stem into the mitre. I feel satisfied that but for the device the gates would have been carried out.

On August 16th, 1912, the steamer "Harry E. Packer" entered the lock with speed, and through some misunderstanding of signals the engineer, instead of backing up, drove the vessel full speed ahead against the gates.

Three large snubbing lines were broken, and the boat struck the right head gate, cutting a 6 in. x 12 in. oak wale through and opening it quite a distance.

The upper finger of the device supporting the left gate broke, which was, so far as can be judged, due to a flaw in the casting. The full load was thus thrown on the lower finger, which held, and prevented a very serious accident.

The injured gate, though badly twisted, was sufficiently repaired in three hours to resume navigation, and later on was replaced by a spare gate.

The device will be placed on at least five more locks this winter.

Trusting the above information covers your requirements, I remain,

Yours very truly,
W. H. Sullivan,
Superintending Engineer,
Welland Canal.

St Catharines, Nov. 21st, 1912.

CANADIAN ENGINEERS AND DRAUGHTSMEN.

Sir,—The article on the above subject in your issue for the 14th inst., while offering some good suggestions, makes some rather amazing statements. The writer attributes the scarcity of capable draughtsmen in Canada chiefly to the large proportion of people whose parents were "nothing but farmers." In other words, boys who hail from the country are thereby partly incapacitated from thoroughly learning engineering, and, presumably, any profession. I quite disagree with this. History and biographies show again and again that the real genius comes from the country and seldom from the city, and in no sphere of life is this more true than in engineering. Telford, Watt, Stephenson, and a great many other engineers in our own day came straight from the land. Practically all the great authors and poets owe their genius to mother earth. Most of the great statesmen, Gladstone excepted, were country bred. Everyone knows the story of Abraham Lincoln.

To my mind, the reason why the Canadian-born draughtsman, as a rule, has not had the experience, and does not possess the initiative of his competitors, is that competition in a new country like Canada is not keen enough. In Britain, no one without shop experience could get a job as draughtsman. To a large extent, drawing offices in Canada seem to be recruited from a few college students and many tracers, instead of from young men who have just completed a shop apprenticeship. On the latter point I quite agree with the author of your article. One reason, I consider, why young Canadians do not stay long enough at the drawing-board to acquire thorough experience is the fact that in many offices a draughtsman's lot is a dog's life of push and drive. The man quietly makes up his mind to get out at the first opportunity and into some opening where there is a little more mutual trust and confidence.

As to the suggested increase in technical schools, I maintain that this has been overdone in England to such an extent that the market value of a knowledge of mechanical engineering design has been reduced to 35 shillings a week ($8.40). My experience has been that the quickest draughtsmen are often those who have not a superabundance of technical knowledge, as they do not stop at every turn to worry themselves about theoretical considerations. This statement will probably meet with opposition.

Without trespassing further on your valuable space, I shall conclude with a short reference to the much-maligned premium apprentice system. Don't pay a premium if you can help it, of course. Personally, I owe my practical training to this system, as without it I could not have got a start in an engineering works, having no friends or relatives who were ever connected with the business. In Europe, at all events, the premium apprentice is the only form in which new blood comes into a concern. Almost all the mechanical engineers of the British railways are from the ranks of premium apprentices.

C. Oldrieve Thomas.

Montreal, Nov. 20th, 1912.

25-CYCLE CURRENT FOR LIGHT.

Sir,—It has occurred to me to wonder if any one has considered the probable effect on eyesight of the disagreeable flicker noticed with lights deriving power from Hydro-Electric System. This would appear to be due to the fact that they are using 25-cycle alternating current. I have not seen any explanation as to why the 25-cycle current was chosen, as it must surely have occurred to the devisers of the system that this was approaching very closely to the limits of persistence of vision so that a sensitive eye readily notes the flicker due to the comparatively slow alternation of polarity. It is a point that deserves consideration by expert oculists.

Yours truly,

J. EDW. MAYBEE,
Ridout & Maybee, 59 Yongs St.,
Toronto.

Nov. 22nd, 1912.

PRESERVATION OF TIES.

Sir,—Your issue of November 14th contains an article written by Mr. E. A. Sterling on "The Development and Status of Wood Preserving Industry in America," in which he gives a summary of the various processes of treating methods now in use in this country. He divides the different kinds of treatment into three classes, namely, (1) high artificial pressure process, (2) atmospheric pressure process, and (3) low artificial pressure process. Each of these is again sub-divided into two classes, namely, (1) "full-cell" and (2) "empty-cell." This is quite a foxey classification, but it is inconsistent and is not entirely in accord with the facts. In the first place he omits to mention in his summary the "boiling in oil process," which is used to a considerable extent in the West, and we would be curious to know in what class he would include that process. Again, he does not describe how "full-cell" and "empty-cell" treatment is secured or performed with "low artificial pressure process," as he does for all the others mentioned in his schedule, and leaves one to guess as to how it is accomplished. Nor does he make clear what he means by "high artificial pressure" and "low artificial pressure." Is it not true that the pressure in the impregnating cylinder may be anywhere from one pound to 250 pounds, or even more? Therefore, wherein is the distinction between the two processes? If there is any, when and by whom was the line of demarcation established?

In regard to the so-called "full-cell" and "empty-cell" process, I desire to repeat here what I have often expressed orally and in writing, that there can be no such distinction between different treating processes, and that these words were coined by exploiters of patented creosote processes to humbug and bamboozle the uninitiated. These so-called "empty-cell" processes are nothing more than "partial dose" processes, injecting only a limited quantity of creosote oil into the timber, and in many instances the proper seasoning and preparation of the ties before treating, which is so essential for good work, are ignored.

I would summarize the methods in use in this country at the present, as follows:

Artificial Pressure Processes.

Full Dose.—Impregnation done in closed cylinders. Preservatives injected in the wood to total refusal, after the wood is put into a receptive condition by air seasoning, or boiling in steam or oil. Preservatives mostly used are creosote oil, zinc chloride, crude oil and other chemicals and solutions. Penetration and diffusion as thorough as the condition of the wood and process of treatment will admit.

Partial Dose.—Impregnation done in closed cylinders. Duration and amount of pressure regulated so as to inject a limited quantity of preservative into the wood. Creosote being the only preservative used in this process. Penetration usually scant except in sapwood and the variation in absorption in individual ties is very large.

Atmospheric Pressure Processes.

Light Dose.—Impregnation done in open tanks. Preservatives usually creosote oil, crude oil, or carbolineum. Quantity absorbed depending upon the temperature and nature of solution, character and condition of the wood. Treatment only superficial.

The Lowry and the Rueping processes come within the category of "partial dose, artificial pressure process."

Mr. Sterling states that the present tendencies are towards lighter impregnation with creosote and that no less than sixteen plants use a light impregnation creosote process. While not specifically so stated, the impression left on my mind after reading this article, and I think on that of most readers, is that it is economical to treat ties with a light dose of creosote. We do not believe these light treatments are economical, and possibly some of the railroad companies treating their ties with light doses of creosote are making a great mistake.

Treating railroad ties with light doses of creosote oil has shown emphatically by experience, a very unwise thing to do. For motives of economy some of the French railways undertook to reduce the quantity of oil injected into their ties, from full dose to partial dose, and met with unfavorable results. Why should we not profit by past experience and treat ties to refusal, instead of repeating these mistakes

In France where the creosoting of ties is an old industry, heavy treatment has been the rule, forcing into the timber all of the creosote that it would take. In England, also, the creosoting of railroad ties is an old industry, but, on the average, a somewhat smaller quantity of creosote per unit volume of timber has been used than was common practice in France. In comparisons of the practical results obtained in the two countries it has always been reported that the life obtained from creosoted ties in France was longer than in England, purely and simply because of the larger amount of material used per unit of the treated timber. If the long-standing results of experience in these countries have been correctly represented, and if any significance attaches to them, we fail to see the logic in much of the supposedly experimental work that has been done in this country. If the life of the timber depends upon the amount of preservative injected, as long-time experience seems to teach, then skimping the material might be expected to result as skimping usually does in other engineering work, no matter under what name or disguise the art is practised. The old adage, "Anything worth doing at all is worth doing well," is eminently fitting in the treatment of ties and timber.

W. F. GOLTRA, President,
The W. F. Goltra Tie Company.

Cleveland, Ohio, Nov. 22nd, 1912.

◆

ELECTRICITY AND REINFORCED CONCRETE.

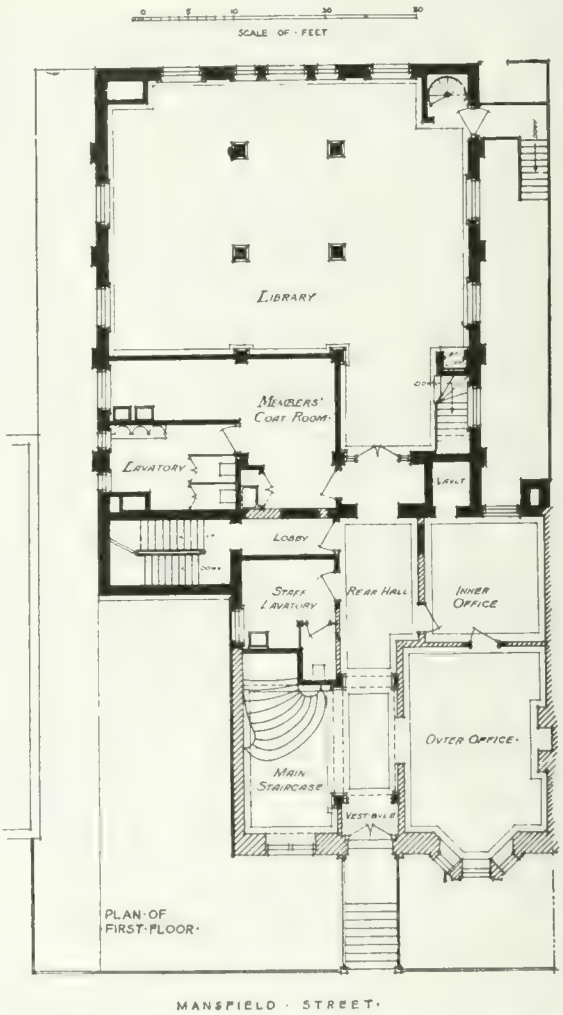
A description and data of tests on the action of electricity (stray direct currents) on reinforced concrete made at the Technical School at Darmstadt, Germany, are given in a recent issue of Le Génie Civil, and abstracted in the Journal of the American Society of Mechanical Engineers. With concrete blocks placed in air on a layer of moist sand, or in sweet water, and subjected to the passage of a current of 0.1 ampere at 140 volts, fissures appeared after a period of from 50 to 110 days, the location of the fissures depending entirely on the position of the anode; in blocks placed in salt water they appeared at the end of from 20 to 70 days, and the concrete was colored in the neighborhood of the fissures first greenish gray (ferrous oxide), and after some exposure in the air, brown (ferric oxide). Fissures appeared in blocks immersed in chalk water in about the same time. A series of experiments led to the belief that these fissures were produced not by an evolution of gases, but by a thickening of the iron anode enclosed in the concrete, owing to superficial oxidation. By further tests it was found that the resistance of the reinforcing members to being torn out is increased by the action of the current, which may be explained by the formation of a layer of oxide adhering to the concrete more strongly than the original clean line.

THE NEW HOME OF THE CANADIAN SOCIETY OF CIVIL ENGINEERS.

As is well known, the Canadian Society of Civil Engineers sold their property at 413 Dorchester Street, Montreal, recently, where their rooms have been located for some time, and have acquired a new location at 176 Mansfield Street, Montreal.

On this location they are building new rooms which, it is expected, will be ready for occupancy for the annual meeting.

The building is very commodious, and is designed to secure the maximum advantage of the available space. The old house which stood on the lot at the time of its purchase has been remodelled to suit office requirements, and a new two-story building is now in process of construction in the rear. The new structure will provide an auditorium, giving seating accommodation for 225 persons. A library, reading rooms, and dressing rooms are also provided. In the basement is located the heating and boiler equipment, and a very large bookstack room, affording adequate storage accommodation for unbound engineering literature not suitable for the library shelves and for the surplus stock of publications of the society. The plan of the first floor, as seen in the cut, shows the offices, cloak rooms, and the library located there. On the second floor is located the reading room, the board room and the lecture room. The attic floor



First Floor Plan of New Premises of the Canadian Society of Civil Engineers.

is laid out to provide two bedrooms, a living room, kitchen, store-room and bath-room.

The cost of the lot and the old building amounted to $47,100, and the contracts for alterations to the old building and construction of the new building to $36,449, making a total expenditure of $83,549. This amount will have to be supplemented to a small extent by the purchase of additional furniture and minor contingencies.

Building operations are now well under way, and it is expected that the premises will be ready for occupation on January 1st next.

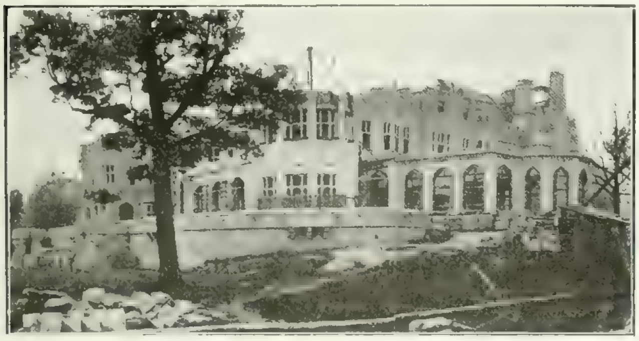
◆

A STEEL, STONE AND CONCRETE RESIDENCE.

The illustration depicts the exterior of a residence that is possibly without a rival on this side of the Atlantic. It is situated on Wells Hill, overlooking the city of Toronto, and is being constructed for Sir Henry Pellatt.

The exterior undoubtedly is a good representation of an ancient baronial stronghold and is very similar to structures now standing in various parts of Europe, but the interior at once shows several marked departures in construction methods from those generally employed in residence building.

The main entrance faces toward the south, but as this is inaccessible to carriages and automobiles an entrance for these has been constructed in the rear of the building to which a long winding driveway leads; this entrance opens into the main reception hall, which is a very large room, and will contain the base of the grand staircase and a pipe organ with a balcony for an orchestra. A library to the east and a dining room to the west occupy the entire front of the building and from a hallway passing by the library entrance is gained to the palm house and swimming pool; practically all the eastern section of the house is taken up by the latter.



New Residence for Sir Henry Pellatt, Toronto.

An underground tunnel has been constructed whereby the stables may be reached without going outdoors; the entrance to the tunnel from the residence is reached from below the base of the main staircase.

The method of interior construction is entirely along the lines adopted in the erection of modern office buildings. Many steel beams are used and the floors are all of interlocking tiles covered with concrete and the various pipes used for steam heating and electrical insulation.

When the structure is completed and the floral decorations are properly arranged it will be a handsome addition to the buildings and architectural interests of Toronto.

The architect for this work is Mr. E. J. Lennox, Toronto.

GRADE ELIMINATION AND RAILROAD BRIDGES.*

By C. H. Tinker.

I have been asked to make a few remarks upon some of the details of construction in connection with the design of grade elimination and railroad bridges. This subject has been studied by railroad employees for a number of years. From experience with the early bridges, there have been two or three points developed which it seems necessary to consider in the design of such structures. Some of the early bridges which carry trains over the street are quite noisy and are objectionable on that account. If any one will visit Lakewood and stand under Clifton Boulevard bridge, he will understand what I mean. The rails rest directly upon the floor plate, held down by clips, and every time a train goes across, it produces a roaring sound which can be heard for a long distance; in fact, it is hardly possible to hear anything else while the train is on the bridge. It seems desirable to avoid this objectionable roaring, and considerable study has been put upon that point.

To determine how the noise could be best reduced, bridges of various types in several cities have been observed with that point in mind. In the city of Pittsburg, near the Pennsylvania station, there are two bridges which carry the Pennsylvania tracks across Penn Avenue and Tenth Street, and it is remarkable how little noise can be heard from a train crossing these bridges. When the reason is sought, it is, at first, difficult to see. However, on both bridges there is a deep bed of ballast which carries the track, so that the effect is an ordinary roadbed crossing the street by a bridge.

In the city of Chicago, there are a number of bridges which are apparently of similar construction, and yet the noise is quite pronounced. It is probable that there is not very much ballast upon the deck of these bridges, and that fact has apparently considerable effect upon the amount of noise produced. There is also a great deal of noise produced by the passage of street cars underneath the bridges, and in the case of some bridges the street cars make a great deal more noise than the railroad trains do. Where the beams forming the floor of the bridge are exposed below, forming air pockets between them, the passage of the car sets up a reverberation. There is a similar reverberation noticeable in a through girder bridge. The sound seems to rebound from one girder to the other, back and forth, until it produces a continuous roar.

It is also noticed that where the floor of the bridge is heavy and there is considerable concrete, the noise is much less. At the Detroit Avenue bridge over the Nickel Plate tracks in Cleveland, the bridge carries the roadway with the street car tracks across the railroad. The beams are exposed below, but they are covered with concrete to a thickness of some two inches on all sides. There is a sand and brick pavement on top of the concrete slab, and the street car tracks are carried upon steel ties which rest directly upon the beams. There is a slight reverberation noticeable from the passage of street cars over that bridge, but the noise is not objectionable.

Following out this line of investigation, the observations seem to indicate that if a bridge be constructed with considerable depth of ballast that the vibration of the rails and the parts of the bridge would be reduced. And, further, that if a smooth under-surface of the floor is obtained that there will be very little opportunity for a reverberation underneath the bridge. This is very well illustrated by the present Euclid Avenue bridge on the Nickel Plate Railroad.

---

* Paper read before the Cleveland Engineering Society

The noise from the passage of trains there is very slight. A person may stand under the bridge and hear ordinary conversation with ease while a train is passing. The space between the beams is filled with concrete, producing a smooth under-surface, and there is about two feet of ballast on top of the slab which carries an ordinary roadbed. So, we think that the reduction of noise is accomplished by attention to these details of construction.

Another point which has caused a great deal of thought is the nuisance from the dripping of water through the bridge floor upon the street below. This is objectionable even when the amount of water passing is quite small, because the water passing through ballast, trickling down through the interstices of the floor slab collects various substances such as lime, grease and iron rust, which, dripping upon passers-by, may ruin their clothes. Therefore, it has become necessary, and is required by ordinance in some cases, that bridge floors should be waterproof.

A great deal of study has been put upon the subject of waterproofing masonry, and especially the waterproofing of bridge floors, which seems to be one of the principle things requiring waterproofing. The American Railway Engineering Association through its Masonry Committee, has had this subject under investigation. The committee has made three progress reports, but has not, as yet, published any definite conclusions. The committee has found this to be a large subject, and one upon which almost any proposition may be proved if the contradictory instances are ignored.

There are several companies who are exploiting various waterproofing compositions. They have had a large growth in the last few years, partly because of the necessity for waterproofing structures of this kind. There are many substances which are more or less impervious to water. In fact, nearly every substance is impervious to a degree; some very slightly, some very much so. A wooden plank offers a certain resistance to the passage of water; so does a slab of stone. Under some conditions considerable water will pass through either. Various substances of a hydrocarbon composition—asphalt, coal tar and petroleum products—seem to be quite impervious to water under certain conditions. Many substances are on the market for incorporation with the sand and cement to make impervious concrete. The theory is that these substances make the concrete so dense that water cannot percolate. Extravagant claims are made for some of these materials. Some engineers believe that for the waterproofing of masonry—and masonry now-a-days means concrete—about the best thing is concrete. The accepted method of waterproofing a concrete slab in a bridge floor is to place upon it a layer of ½-inch to 2-inch thickness of some of the asphalt, coal tar or petroleum product gums, with which may or may not be included several layers of burlap or felt paper. Now, a small surface covered with these substances will hold water indefinitely, but when you spread them over a large expanse of bridge floor, there are other difficulties to be met, and the greatest of these is the expansion and contraction from temperature. Asphalt itself, if its condition remains unchanged, is quite impervious to water, but if it contracts through cold, and cracks, the water will pass through the crack. It takes a very small crack to produce a leak which is objectionable in a bridge floor, and therefore it is necessary to have a substance which will expand and contract with the slab and not crack. This leads to the other extreme, that is, a substance so soft that when it becomes warm it will run. There are bridge floors in Chicago which leak asphalt. It is therefore clear that it is not a simple subject, and for any man to guarantee off-hand that any particular waterproofing composition will make a watertight bridge floor is rather hazardous. It is true, instances may be found of bridge floors which are apparently watertight, but there are more instances where this is not true. I think I may say that a well built slab of concrete is fully as impervious as a poorly built slab with any style of waterproofing.

In connection with the above method of waterproofing bridge floors, the asphalt, coal tar or petroleum products used require protection against abrasion and damage from external causes. This requires a still greater thickness. Many bridge floors have been built with a protection of brick on top of the asphalt. They have been fairly successful from a waterproofing standpoint, but the finished waterproofing adds in the neighborhood of 6 inches additional thickness to the bridge floor, and it is the opinion of a good many that that 6 inches could be better utilized by placing 6 inches of concrete on the floor.

In the bridges recently built in Cleveland by the Nickel Plate no foreign waterproofing substance has been used. An attempt has been made to construct a concrete slab which would be in itself as nearly waterproof as it is practicable or desirable to make. This has proved satisfactory. When the Cedar Avenue bridge floor was built, the ends of the bridge were dammed up, the trough so formed was filled with water and allowed to stand for several days. No water whatever came through at any point of the slab. A little water ran through the dam and down over the back wall, and seeped through the joint between the bridge seat and the floor slab. At the centre bent there is a drainage system provided to carry what water might percolate through at that point down to the gutters. Through some slight defect in the formation of this drainage some water seeped through there and dampened the concrete, but at no point of the bridge did any water drip.

One of the most essential things in the successful waterproofing of a floor slab is to get rid, in the most direct manner, of all the water that accumulates. That means that a drainage system must be provided which will be ample to take care of all of the water which can be collected upon the bridge floor. This sounds simple, but it is quite difficult. These drainage systems have to be carried some distance; they have to pass around a great many angles and eventually reach the level of the street gutters or of the sewer. At the Euclid Avenue bridge such a drainage system is in place. When the bridge was first completed it was discovered that at some point between the bridge floor and the sewer the drain pipe was clogged, with the result that the water did not run away, but stood in the drainage gutter and eventually soaked through the concrete. This illustrates the care and painstaking attention to detail necessary to secure the desired results. This pipe has since been cleaned out so that water runs away readily.

The essential points in constructing a watertight floor slab are: Dense concrete—the denser the more impervious; intelligent study and design in the location of expansion joints the provision of an ample drainage system; careful workmanship and constant supervision during construction.

Another point which has developed from experience with bridges over the tracks where the under-clearance is low, is that the blast from the engine has a very detrimental effect on the structure overhead. In the city of Chicago it has been determined that where the clearance is about 18 feet the steel will be worn away by the engine blast at the rate of about ¼ inch in ten years. That means that the flange of an I-beam would be so much deteriorated in ten years that the beam would have to be replaced. This has occurred in some instances in Chicago.

At the Detroit Avenue crossing of the Nickel Plate the clearance is 16 feet 3 inches, which is the general rule in

Cleveland. The I-beams in this case are covered with concrete to a thickness of 1½ to 2 inches; it was found in the course of a few years that the engine blast eroded the concrete, so that in about five years there is a bare streak of steel over the centre of the track. At the Adelbert Road and Cornell Road bridges it was decided to place cast iron plates immediately over the centre of the track. These smoke plates are about ½ inch thick. The engine blast will not be as destructive as upon steel, the cast iron being harder and when the plates are destroyed they can be replaced with little trouble and expense. In some cities a wood plank has been used for this same purpose. In the city of Philadelphia, the Philadelphia & Reading Railroad placed a wooden ceiling under their steel bridges. These gave fair satisfaction for several years.

Our experience is that a concrete covering will be satisfactory for a few years, but where the head room is low, as is apt to be the case in cities, that it will not protect the steel permanently. It must then be replaced, and it is well known that to repair an old, worn surface of concrete is likely to prove a difficult and costly operation.

One point in connection with the subject of co-operation. In some cities, there has been a tendency to design the work of grade elimination at the least possible expense. That means the lowest height for retaining walls, the least difference between the grade of the railroad and the grade of the street and the least thickness for bridge floors. This is unfortunate. While it is true that a bridge floor may be built quite thin, it is not satisfactory; it leads to the objectionable designs which I mentioned. Wherever the bridge floor consists of simply I-beams and steel plate, which is about as thin as a bridge floor can be made, there will be noise and leakage. In order to reduce the noise to a minimum, to reduce leakage to a minimum, it is necessary to have a reasonably thick bridge floor. In recent designs in the city of Cleveland about 4 to 4½ feet has been adopted. With this thickness a very satisfactory floor can be made, and it is believed that the additional expense due to the increased height and length of approaches is offset by the greater length of the life of the structure, and by the greater satisfaction which accrues from its use.

AMERICAN ROAD BUILDERS' ASSOCIATION.

Plans for the Third American Good Roads Congress under the auspices of the American Road Builders' Association, which will open at Music Hall, Cincinnati, Ohio, Tuesday, December 3, are practically complete. Reports from the officers of the association and the several committees charged with the work of preparing the programme, arranging for the allotment of exhibition space and the entertainment of visitors, etc., indicate that this congress will surpass in interest and actual value to the paving and road building industry any previous meeting ever held.

The exhibit of the United States Office of Public Roads will consist of models of modern roads of different types and historic models showing the evolution of road building from ancient times to the present. The exhibits of the states and cities will comprise maps, charts and photographs showing various methods of building roads and streets, models of the different kinds of work, testing machinery, samples of materials, etc. The exhibits of the engineering schools will consist of maps, drawings, diagrams, photographs, charts and outlines of the engineering courses, as carried on in the several institutions.

The tentative programme which will be carried out practically as prepared, with a few minor changes and additions follows:

Tuesday, December 3.

8.30 to 11 a.m.—Registration of delegates at convention headquarters, Music Hall.

11 a.m.—Congress called to order by the president. Address of welcome on behalf of the State of Ohio. Address of welcome on behalf of the city of Cincinnati. Address of welcome of behalf of Hamilton County. Address of welcome on behalf of the Cincinnati Chamber of Commerce. Response on behalf of the American Road Builders' Association. Response on behalf of visiting state officials. Re-Response on behalf of visiting city officials. Response on behalf of visitors from other countries. Appointment of committees.

2.30 p.m.—Opening address by the president of the American Road Builders' Association, Nelson P. Lewis. "The Organization of a Highway Department": (a) For a State, by Major W. W. Crosby, consulting engineer, Baltimore, Md.; (b) For a large city, by Wm. H. Connell, chief of the Bureau of Highways and Street Cleaning, Philadelphia, Pa.; (c) For county and township, by A. N. Johnson, state highway engineer of Illinois. Discussion to be opened by James Macdonald, state highway commissioner of Connecticut. "The Development of a Plan for a State Road System," by James R. Marker, state highway commissioner, of Ohio. Discussion to be opened by Col. E. A. Stevens state highway commissioner of New Jersey.

Wednesday, December 4.

10 a.m.—"Bituminous Pavements for City Use," by George W. Tilson, consulting engineer to the Borough of Brooklyn, New York City. Discussion. "Wood Block Pavements Laid by Day's Labor," by Ellis R. Dutton, assistant city engineer of Minneapolis, Minn. Discussion to be opened by H. W. Klausmann, city engineer of Indianapolis, Ind. "Cuts in Newly Paved Streets," by H. M. Waite, city engineer of Cincinnati, Ohio. Discussion.

2 p.m.—"The Contractor's Point of View," by Hugh Murphy, contractor for public works, Omaha, Neb. Discussion to be opened by S. D. Foster, chief engineer, State Highway Department, Pennsylvania. "Plant Equipment," by F. E. Ellis, manager, Essex Trap Rock and Construction Company, Peabody, Mass. Discussion.

8.30 p.m.—The visiting delegates will be the guests of the citizens of Cincinnati.

Thursday, December 5.

10 a.m.—"Some Features of Macadam Construction," by T. R. Agg, road engineer, Illinois State Highway Commission. Discussion to be opened by R. A. Meeker, state highway engineer of New Jersey. "Earth and Gravel Roads," by Robert C. Terrell, commissioner of public roads of Kentucky. Discussion to be opened by Robert J. Potts, College Station, Texas. "Highway Bridges and Culverts," by W. A. McLean, engineer of highways province of Ontario, Canada. Discussion to be opened by A. W. Dean, chief engineer, Massachusetts Highway Commission.

2 p.m.—"The Economics of Highway Construction," by Clifford Richardson, consulting engineer, New York City. Discussion. "Traffic Census as a Preliminary to Road Improvement," by Col. Wm. D. Sohier, chairman, Massachusetts Highway Commission. Discussion to be opened by Prof. A. H. Blanchard, Columbia University, New York City. "The Laying of 104 Miles of Smooth Road Surface in One Borough in Five Months," by G. Howland Leavitt, superintendent of highways, Borough of Queens, New York City.

Friday, December 6.

10 a.m.—This session of the convention will be devoted to topical discussions. The particular subjects to be discussed will be determined by vote of the delegates. Ballots con-

taining a list of questions will be distributed at the first session and delegates will be requested to indicate their choice. The speakers selected to open the discussions will be allowed ten minutes and other speakers five minutes. This promises to be one of the most interesting and profitable sessions of the convention.

2 p.m.—Unfinished business. Report of the Committee on Resolutions. Meetings of members of the American Road Builders' Association; selection of Nominating Committee.

List of Questions from Which Subjects for Topical Discussion are to be Selected.

1. Small blocks, natural or artificial, for country roads.
2. Convict labor on road work.
3. Correction of alignment and grade in existing highways.
4. Care of the roadside, including tree planting and removal of unsightly objects.
5. Division of expense of road improvement.
6. Unit price vs. lump sum contracts.

◆

ANNUAL REPORT OF THE CANADIAN NORTHERN.

The gross earnings of the Canadian Northern Railway for the year ended June 30th, 1912, as shown in the company's annual report, amounted to $20,860,093. Working expenses were $14,979,048. The net earnings are given as $5,881,045, and the net surplus was $575,396. An increase of $4,499,381, or 27.50 per cent., is thus shown in the gross earnings, while net earnings are $890,698, or 17.85 per cent. greater than the preceding year. The working expenses were 73.82 per cent. of the gross earnings proper, and 71.81 per cent., including taxes, of the gross earnings from all sources, compared with 72.59 per cent. and 69.50 per cent. respectively last year. During the year over 586 miles of newly constructed tracks were added to the system, the average mileage operated being 3,888 miles.

The detailed report follows:—

Gross earnings—	
From passenger traffic	$ 3,434,140.81
From freight traffic	15,567,998.17
From express, mail, telegraph, dining and sleeping cars, interest and profits from elevators and other subsidiary companies and investments	1,857,954.65
	$20,860,093.63
Working expenses (including taxes, &c.)	$14,979,048.52
Net earnings	$ 5,881,045.11
Deduct—	
Fixed charges (per statement, page 17)	4,630,844.12
Surplus	$ 1,250,200.99
From this deduct interest at 5% per annum paid on income charge convertible debenture stock outstanding	674,804.11
Net surplus for the year	$ 575,396.88

An increase of 120 per cent. in the total bulk of commercial coal carried is also remarkable, the figures being 804,803 tons moved this year, compared with 370,161 tons for the previous twelve months. This increase is indicative of the growth of the coal mining industry in Western Canada, which, upon the completion of the extensions now being constructed in the larger coal areas, will receive an even greater stimulus. There is also a further indication of the prosperous extension of the cities, towns and settlements along the lines, as shown by the increase of 48 per cent. over last year in the amount of building materials carried by the railway during the year.

Land sales during the year were 55,111 acres for $836,084.37, an average of $15.17 per acre, compared with 279,151 acres for $3,345,498.73, an average of $12.00 per acre, the preceding year. The reduction in sales is substantial, but the directors, recognizing that the value of productive acreages in Western Canada is assured, and being desirous of, as far as possible, selling to settlers only, have not pressed the sale of lands. On the other hand, they have adopted an agressive policy of colonizing the free lands offered by the Dominion Government in territories adjacent to the railway. Two million four hundred and seventy-nine thousand acres of these lands were entered upon by settlers during the year, of whom a largely increased number were a most desirable class of British emigrants.

The operation of the Royal Line of steamships continue to vindicate the wisdom of engaging in the Atlantic trade. The increasing popularity of the route emphasizes the necessity for extending the service so that the company may take the full benefit of the business controlled by its organization.

Great progress has been made in the construction of the transcontinental line of the Canadian Northern system, which it is hoped will be completed by the end of 1913; the line through British Columbia to connect the western lines with tidewater at the Pacific Coast is advancing rapidly. In addition to a very fortunate advantage of easy gradients the location of the line enters without competition into a large territory, the physical characteristics of which will attract a very desirable class of settlers. The line will also give access to an hitherto unknown section of the Canadian Alps, of which the scenic attractions are such as will divert a large volume of the transcontinental tourist traffic to the route.

The work of linking up the lines in Western Canada with the railways of the Canadian Northern system in the eastern provinces is making satisfactory progress, having regard to weather and other conditions. The resources of the country opened up by this line will be productive of great traffic advantages. Capital is only awaiting the completion of these transportation facilities before entering upon the development of iron and other mineral deposits, extensive pulpwood and timber areas. In addition to the tonnage assured from this industrial development, there are the traffic advantages which will accrue from the agricultural development of the great clay belt of Northern Ontario, through which the railway will pass for a distance of three hundred and fifty miles. Experienced officers who have carried out explorations of the entire area estimate that the industrial and agricultural resources of this territory will attract and support a population of over two million of people.

During the year another section of the Canadian Northern Ontario Railway was opened for traffic, but the directors regret that owing to adverse weather and other conditions the completion of the line between Ottawa and Toronto has been delayed. The work is, however, progressing, and it is hoped in a short time to establish a through service connecting Toronto with Ottawa, Montreal and Quebec. The pulp and paper industries in Northern Quebec are expanding quite satisfactorily, the traffic advantages of which chiefly accrue to railways operated under Canadian Northern control in Quebec.

In conclusion, Sir William Mackenzie refers to the numerous prominent men who have recently visited Canada, stating that personal and unbiased examination of the actual and potential resources of the Dominion will result in still greater confidence in the future of Canada and the close cooperation in her development.

THE NEW OFFICES OF THE BANK OF TORONTO.

By Lyman B. Jackes.

Visitors to the larger and older Canadian cities must be at once impressed with the idea that the architecture of the newer structures is changing. Not only with the mode of construction and the use of steel and concrete, but in the design itself, and the expenditure of vast sums of money for no other purpose than the cultivation of the aesthetic. The new wing of the provincial parliament buildings may be taken for an example. Here the new adjoins the old with a short corridor between. The old is of the most inflammable construction; wooden floors and plaster walls with oak decoration and finish. The new is of fireproof construction; tile floors, marble walls and wainscoting, and metal covered doors that shut off various sections of the new portion. Over the new entrance to the building an elaborate stone cutting has been made representing the arms of the province and in every way the beauty of the new section outclasses anything that the old may show.

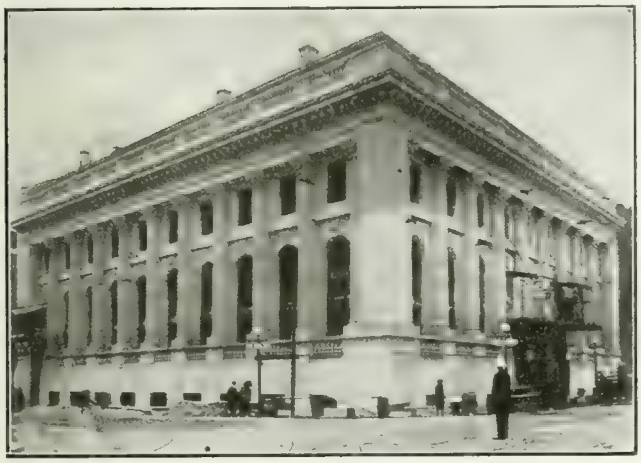

Fig. 1.—New Bank of Toronto Building.

Another example may be seen in the immediate vicinity of King and Bay Streets. A few months ago this was a corner almost a disgrace to the business section of the city with old tumble-down buildings (some mere shacks that had survived from the old days) devoted to small businesses such as the manufacture of keys (retail) and lunch rooms. To-day that corner will hold its own in architectural beauties with any similar block on the North American continent; but, it is to the latest addition to the section, the new offices of the Bank of Toronto, to which we direct tht attention of our readers.

This bank has for a number of years owned the property at the southwest corner of King and Bay Streets, with the object of erecting a new head office, but declined for many years to take a forward step until the character of the neighboring buildings could be more definitely learned. When this became suddenly the commercial centre of the city the bank announced that they would erect a million-dollar office building on their site.

It was at first expected that this would involve the erection of a sky-scraper, but a further announcement was made that the building would be but one and a half stories in height, and that the sum of one million dollars would cover the building expenses only and did not include the value of the land.

Million-dollar buildings were not a novelty to Torontonians, but the associations always accompanying such a thought were of magnitude and did not include anything of the artistic. As the new bank is rapidly nearing completion and the exterior false work is being cleared away there comes into view a building that rivals any temple ever erected by the ancients, and will be looked upon with pride by the passers-by as well as the bank directors.

The King and Bay Street facades, as may be seen from an examination of Fig. 1, is composed almost entirely of circular pilasters surmounted with a cap in the Greek Corinthian Order; there are eleven columns on the Bay Street side and ten on the King Street front.

All the exterior stone work is of Tennessee marble and practically all the carving was done after the stone had been placed in position. The carving was done with the aid of chisels driven by compressed air, the plant for supplying the air is illustrated in Fig. 2.

The interior decorations and finish will consist of polished marble stone ornaments and bronze work. The double row of windows shown in Fig. 1 would give a passer the idea that two floors were represented, but such is not the case, the public banking room extends right up to the ornaments capping the columns. The banking room ceiling, as examined from below, will show a plate of heavy, semi-transparent glassware, which shows through an elaborate pattern cast in the bronze. This bronze work is to slope upward from a wall of polished marble and will support various decorations and figures and then form a screen to allow the light filtring through the glass to reach the desks below. The weight of this metal will be enormous.

A beautiful stairway on the northern side of the public office leads to the private office which cannot be seen from the street or from below; these are placed back of the upper railing shown in Fig. 1., surmounting the abutment. The windows and doors of the private offices open onto a hallway, the outer wall of which forms the walls of a roof garden that utilizes the semi-transparent glass as a floor.

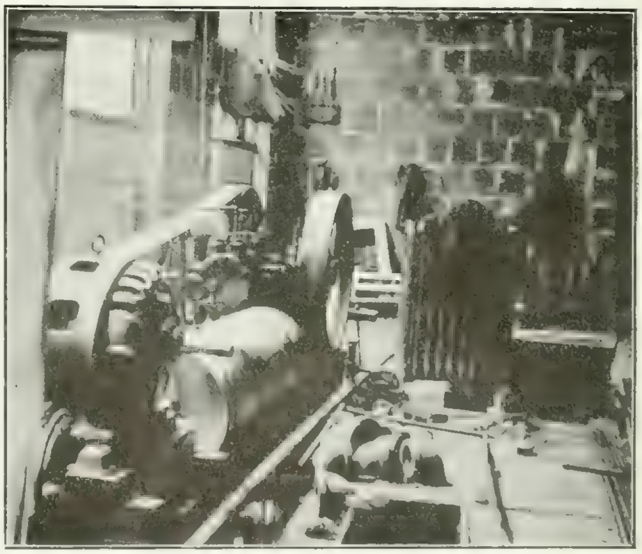

Fig 2.—Air Compressor Plant.

Taking the building as an entirety it is a novelty from the archtectural standpoint and a handsome addition to the buildings of Toronto.

Messrs. Henry Hope and Sons, Limited, 45 King Street West, Toronto, have furnished the steel frame and casement work for the windows. The lower windows will have a height of 21 feet and will be divided into two sections by a bronze panel.

Messrs. Carrère and Hastings and Eustace G. Bird, Traders Bank Building, Toronto, are the architects.

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

METALLOGRAPHY OF IRON AND STEEL.

Sir,—In his kind and able review of my book which appeared in your issue for November, 1912, the reviewer expresses some astonishment that I should deal with the equilibrium diagram of iron and steel and with the phase rule at the end of the book instead of at the beginning. I am well aware that many teachers of metallography—probably the great majority of them—begin with a description of the diagram and of the phase rule as, in their opinion, the most logical and satisfactory course to follow. After some fifteen years of teaching I have come to the very opposite conclusion, namely, that it is better to postpone the study of the diagram and of the phase rule until the end of the course, and I hoped that my book would have demonstrated to the readers that I was right—that it was more logical and profitable to start with the simplest matters and to finish with the more complex considerations. To begin with the diagram and the phase rule is discouraging to the student unless he be a highly trained man, well drilled in scientific methods. In following the other course, on the contrary, it is an easy task to interest the student at the very start, to keep him interested and to lead him by gentle steps to the consideration of those subjects which at the start would have proved very unattractive to him.

In regard to the determination of carbon by microscopical examination, I still think, notwithstanding your reviewer's remarks, that, when applied intelligently and confined to annealed hypœutectoid steels it is as accurate as the colorimetric method. Of course, it presupposes that the steel is homogeneous but so does the chemical analysis. It is not my experience that the results "only hold for the surface examined because the steel one-eighth of an inch below its surface may be and often is of different carbon content."

The separate paging of the lessons was adopted with a view of facilitating the preparation of subsequent revised editions as it makes it possible to remove bodily from the book any lesson, to rewrite it and to replace it without disturbing the balance of the work. It seemed to me that such a very great advantage outweighs so much the slight disadvantages of this departure from the usual custom as to justify the course adopted. Yours very truly,

ALBERT SAUVEUR,
Harvard University, Cambridge, Mass.

November 5, 1912.

Sir,—In reply to Professor Sauveur's letter, I would point out that Professor Sauveur admits himself that the great majority of teachers of metallography have found it advisable to deal with the Equilibrium Diagram of iron and steel before attempting to explain the structure of individual samples of iron or steel. Quite true,—the student's interest may be stimulated at the start by taking up a few examples of iron and steel by themselves; but, to take up the whole subject, as Professor Sauveur has done in his book, before reaching the equilibrium diagram, means that the student [illegible] confused, whereas, if the underlying principles covering all irons and steels are taught him first by considering the equilibrium diagram, he is then able to follow very easily the differences in structure of the various irons and steels. It would be logical, as Professor Sauveur says, to begin with the simplest matters and to finish with more complex considerations. In this case, however, one cannot truly understand even the simplest cases without a knowledge of the equilibrium diagram. The equilibrium diagram is the foundation. When this has been considered one is at liberty to begin at the simplest cases and proceed. The point is, that without first understanding the principles of the equilibrium diagram, the student is apt to think of each iron or steel sample as a separate case, whereas all the irons and steels constitute a series.

Without regard to the determining of carbon by microscopic means, it cannot be denied that metallographic examination is purely a surface test, and one can never hope to replace chemical methods, which depend upon samples being taken by means of a drill from various portions of the specimen, by metallographic observation. Yours very truly,

THOS. R. LOUDON,
Metallurgical Engineer, Toronto.

BOOK REVIEWS.

Reviewed by T. R. Loudon.*

Analysis of Metallurgical and Engineering Materials.—A Systematic Arrangement of Laboratory Methods. By Henry Wysor, B.S., assistant professor of analytical chemistry and metallurgy in Lafayette College. The Chemical Publishing Co., London: Williams & Norgate (14 Henrietta Street, Covent Garden, W.C.). Cloth: 8½ x 10½ in.; pp. 82. Price, $2, net.

The object of this manual is to present the work of the chemical analysis of metallurgical materials in an up-to-date logical order, both for the use of the college student and the practical chemist The departments outlined are given at the end of this review. It is sufficient to say that the book covers the metallurgical field very thoroughly.

The scheme of first stating the reagents required in a given piece of analysis and then outlining the determination is one that will make the work simple. Too often, the student has to read a great deal of matter not related directly to the subject before getting a definite statement of the reagents required.

The chapter devoted to the heat treatment of metals might be made a little more elaborate. It is a good step to include this department in the book, but, too little information is often worse than useless where heat treatment is concerned.

The book is an excellent up-to-date arrangement of the subject.

The following is a list of the chapters: Introduction; Sampling Ores by Hand; Specific Gravity of Solids; Analysis of Limestone; Analysis of Portland Cement; Analysis of Coal and Coke; Analysis of Iron Ore; Analysis of Chrome-Iron Ore; Analysis of Manganese Ore; Analysis of Copper Ore and Matte; Analysis of Lead Ore and Furnace Product;

---

* Metallurgical Engineer, Toronto.

Analysis of Zinc Ore; Analysis of Iron and Steel Works Cinders; Analysis of Iron; Analysis of Alloy Steel; Analysis of Ferro-Manganese and Iron Rich in Manganese; Analysis of Brass and Bronze; Analysis of Soft Bearing Metal; Analysis of Water; Analysis of Producer Gas; Calorimetry of Coal Coke and Oil; Calorimetry of Gases; Examination of Lubricating Oil; Examination of the Microstructure of Iron and Steel; Heat Treatment of Metals; Atomic Weights; Gravimetric Factors; Bibliography.

Elements of Drawing. By George F. Blessing, M.E., Ph.D., and Lewis A. Darling, E. in M.E. Published by John Wiley and Sons, New York. Canadian agents, Renouf Publishing Co., 25 McGill College Avenue, Montreal. 193 pages; 6 x 9 in.; fully illustrated.

While this book contains much useful information and a great many suggestions valuable to the instructor, it is so carelessly written and edited that it is a very unsafe text to put into the hands of the novice, for whom it is evidently written.

In chapter I. on the selection, care and use of drawing instruments, Fig. 31 illustrates the type of scale recommended for architectural or mechanical engineering work, and is an open divided triangular scale. The use of this scale is illustrated in Fig. 32, but unfortunately the diagram shows a scale continuously subdivided. The text on page 31 says: "To mark off a number of consecutive measurements, such as 2 in., 5 in., 1 in. and ½ in., along any straight line, keep the scale stationary and, beginning at zero, mark off in succession the distances 2 in., 2 in. + 5 in. = 7 in., 2 in. + 5 in. + 1 in. = 8 in. and 2 in. + 5 in. + 1 in. + ½ in. = 8½ in."

It is evident to the experienced what the authors wish to avoid, but what will the beginner do when the sum exceeds 12 inches?

The introductory remarks to Chapter II. are good, e.g., "Good lettering and dimensioning on working drawings is of prime importance and cannot be too strongly urged. The outline and characteristics of each letter and numeral must be carefully studied." One is shocked, however, by the statement on the opposite page that "The bar in both the E and F is exactly midway between the top and bottom of the letter," as well as by the many illustrations throughout this chapter showing the same gross blunder in these and other letters, such as B and S. That the authors know better than this is evident from many of the drawings illustrated throughout the book, e.g., pages 43 to 70.

The authors' limitation of the term "mechanical drawings" to those orthographic projections of an object when the principal lines are parallel to the planes of projection is odd, but their extended definition is very confusing to the beginner.

Chapter V., page 157, "Isometric drawing is based on the principles of isometric projection, but it is beyond the scope of this text to take up the discussion of the principles underlying this art. For the purposes of this work it will be necessary to state only two new principles not included in orthographic projection."

A simple statement may be all that is desirable in an elementary text book, but there can be no excuse for misleading the beginner into thinking that an isometric is not an orthographic projection. Again, principle (1) defining the solid angle and its position relative to the plane of projection is, to say the least, incomplete as a projection consisting of any three straight lines radiating from a point such as to make angles of 120 deg. with each other would satisfy the conditions as stated.

This chapter is poorly arranged for in the introductory article (116) the beginner reads about the uses, advantages and disadvantages of isometric projection before he is given the principles of the projection (art. 117) or an elementary example of it (art. 118).

Strength of Materials. By Mansfield Merriman. Published by John Wiley & Sons, Ltd., New York; Canadian agents, Renouf Publishing Co., 25 McGill College Ave., Montreal. Sixth edition, revised and reset. Cloth; 5 x 7½ in.; 169 pages; price $1.00.

This volume, which is a text book for secondary technical schools on the strength of materials, beams, columns and shafts, was first published in 1897. The book has been so well received in the past that it has now reached its sixth edition. In the fifth edition a new chapter was added on reinforced concrete, especially columns and beams. In this edition a new chapter on combined stresses is added. Numerous changes have been made throughout the book and many new problems introduced.

The book is too well known to need much comment, with the exception of noting the changes in this edition.

Steel Sheet Piling Tables and Data on the Properties and Uses of Sections. Carnegie Steel Company, Pittsburg, Pa. 5 x 7½ ins.; pp. 88; illustrated; paper.

This little book, which may be had from the United States Steel Products Co., 220 King Street West, Toronto, contains a large amount of valuable information, not readily available elsewhere, on the subject of steel sheet piling. While the data concern particularly the three types of steel piling manufactured by the Carnegie Steel Company, what is said applies to a large extent to all forms of steel piling. Some of the subjects treated are the strength of the three forms of piling mentioned under lateral, vertical and longitudinal forces; methods and cost of driving; special driving appliances; pulling; watertightness; uses to which steel piling may be put; general engineering tables bearing on the subject of earth pressures and piling.

The publication should be in the hands of all engineers and others interested in sheet piling.

The Cooking of Coal at Low Temperature, with a Preliminary Study of the By-products. By S. W. Parr and H. L. Olin, has just been issued as Bulletin No. 60 of the Engineering Experimental Station of the University of Illinois.

This bulletin gives the details of experiments in the carbonization of coal at relatively low temperatures, not exceeding 750 deg. Fahr. The studies indicate that the bituminous matter in Illinois coals is in excess of the amount necessary to produce bonding material for the non-coking or cellulose residuum of the coal and that the best cokes are produced when mixtures of fresh coal and non-coking coal materials, such as coke breeze or powdered anthracite, are used. The tests show that the by-products consist of a gas of high illuminating power and heat value (1030 B.t.u.), and tarry material which consist in the main of oils of low viscosity having marked oxygen-absorbing properties.

In a very important aspect, this work constitutes a study in smoke prevention from a chemical rather than a mechanical standpoint, and the results show that bituminous coal in a form for combustion without smoke is at least a theoretical possibility. An interesting feature of the work is the information it affords as to the theory of the coking of coal. The summary touching this point concludes, that "for the formation of coke there must be present certain bodies which have a rather definite melting point" and further that "the temperature at which decomposition and carbonization take place must be above the melting point."

---

* Professor of Architecture, University of Toronto.

Copies of Bulletin No. 60 may be obtained upon application to W. F. M. Goss, director of the Engineering Experiment Station, University of Illinois, Urbana, Illinois.

The Modern Gasoline Automobile, Its Construction, Operation, Maintenance and Repair. By Victor M. Pagé. Published by The Norman W. Henley Publishing Co., 632 Nassau Street, New York. pp. 693; 380 illustrations. Price, $2.50.

The faults in this book (a review is always supposed to find such) are noticeable by their scarcity.

The book is stated to be a "thoroughly practical, non-technical treatise," and is true to that description. Evidently the author is conversant with his subject, and while the work is very comprehensive in regard to the great amount of detail it contains, it is well written and the illustrations, being in many cases reduced from actual scale drawings, are clear and suitably chosen.

By a trained engineer much of the text could be dispensed with, but as this book is intended for owners of automobiles, chauffeurs and others, who may have no engineering knowledge, it is well suited to their needs, and should prove very useful to any reader of this class who may desire to understand his car, and particularly its engine, better.

The "Mechanical World" Pocket Diary and Year Book for 1913. Published by Emmatt & Co., Limited, "Mechanical World" offices, Manchester, England. Price, 6d. net.

This handy little book, now in its 26th year, contains a great deal of useful information on mechanical subjects. It is particularly suited to the needs of draughtsmen and is good value in spite of its low cost.

An electrical pocket book is also issued by the same firm, the style and price being identical with the one here referred to.

Differential and Integral Calculus. An introductory course for colleges and engineering schools. By Lorrain S. Hurlburt, Collegiate Professor of Mathematics in the Johns Hopkins University. New York and London: Longmans, Green & Co. Cloth; 5½ x 8½ in.; pp. 481; illustrated. Price, $2.25, net.

This book is intended as an elementary text book of the calculus. The author, for many years, has taught the subject without a text book, using lecture notes of his own placed in the hands of the students. These notes have been re-written from time to time and are now published in book form.

The book is most clearly written and a very logical presentation of the theory of the differential and integral calculus is given. The illustrations are exceedingly clear, and aid very much in an understanding of the text. The treatise is in every way to be commended to the student and engineer as a text book on the calculus.

Some Facts About Treating Railroad Ties. By W. F. Goltra, president of the W. F. Goltra Tie Company, Cleveland, Ohio. Paper; 6 x 9 in.; 105 pages; 8 folding plates. Price, $1.00.

This little volume is mainly a compilation of papers read before technical societies and articles published in the technical press, with the consequent discussion. The book also includes a discussion of the claims of the empty-cell process of treatment of creosote in which a proportion of the oil injected is withdrawn from the water. The following points are brought out in the author's discussion: The tie should be seasoned before treatment; that they should be treated to total refusal; that zinc chloride alone, and in combination with creosote, is more economical than creosote alone in treating ties to refusal; and that it is useless and impossible to group ties for treatment according to their species, degree of seasoning, proportions of heart, sapwood, etc. A letter along the same line will be found in this week's issue under "Letters to the Editor," written by Mr. Goltra.

The Properties and Design of Reinforced Concrete. Translated and abridged by Nathaniel Martin, C.E., and lecturer on "Reinforced Concrete," Royal Technical College, Glasgow. Published by Constable & Co., Limited, London. Cloth; 6½ x 9 in.; 116 pages; 28 tables; 29 figures. Price, $2.10.

The full title of this volume is "The Properties and Design of Reinforced Concrete, Instructions, Authorized Methods of Calculation, Experimental Results and Reports by the French Government Commissions on Reinforced Concrete."

As is well known, reinforced concrete had its origin in France. In December, 1900, a commission was appointed by the French Minister of Public Works, which embraced a group of engineers whose experience in this material was very wide. The work of this commission extending over the succeeding six years, included a series of experiments directed to the obtaining of results immediately applicable to practice. The report of the commission contains the results of the tests on experimental structures, and of the tests to destruction of several of the structures of the Paris Exhibition of 1900. The report has been much quoted and extracts have appeared from time to time in various English books and periodicals. In this volume the translator offers an abridged English edition which will afford professional men the opportunity to acquaint themselves with the scope of the work of the commission and to have the results at hand in readily accessible form.

The Official Good Roads Year Book of the United States. Edited by J. E. Pennybacker. Published by the American Highway Association, Colorado Building, Washington, D.C. Cloth; 6 x 9 in.; 406 pages. Price, $1.00.

This volume contains a concise digest of the road laws of all the States, a list of road contractors in the United States, a biblography of books, pamphlets, etc., pertaining to road building and maintenance, a list of colleges teaching highway engineering, and the course of instruction, a list of organizations working for road improvements, a directory of highway officials in the United States, a list of manufacturers of road machinery and materials, and a list of patents issued in 1911 in the United States relating to roads.

The book opens with a history of road-building, then, after a digest of the road laws in the different States, an analysis is given of the new suggested State Aid Bill. Chapters are then devoted to types of roads, road maintenance and repair, dust preventatives, highway bridges and culverts, bond issues, appropriation and mileage, and a section is devoted to the use of convict labor on roads.

Altogether, this book forms one of the most valuable additions to road-building literature which has come to our hand. The price, $1.00, in no way represents the value of the material contained in the volume.

Light: Its Use and Misuse, a primer on light and illumination which was published last month by the Illuminating Engineering Society, 29 West 39th Street, New York, has already gone into a second edition. Written in a clear and comprehensive manner for popular reading, this little pamphlet has met with immediate favor. It has occasioned considerable complimentary criticism from people who are generally supposed to have little or no interest in the subject of lighting. From the heads of engineering and physics departments of schools and colleges the society has received numerous letters of commendation, together with requests for quantities of the primer for distribution to students. Architects, engineers, oculists, merchants, and others have also expressed their appreciation of the publication. Several lighting companies are planning to issue it to their customers. One large manufacturing company in London has cabled for permission to print and distribute a large edition in Europe. It is not unlikely that the primer will go into many editions.

Engineering for Land Drainage. A manual for the reclamation of lands injured by water. By Charles Gleason Elliott, C.E., M. Am. Soc. C.E., author of "Practical Farm Drainage." Second edition, re-written. New York: John Wiley & Sons. Canadian agents, Renouf Publishing Co., 25 McGill College Avenue, Montreal. Cloth; 5 x 7½ in.; pp. 339; 60 text illustrations; 15 tables. Price, $2, net.

The first edition of this book appeared in 1902, when the question of land drainage was in a very elementary state. Since that time the development and extension of land drainage work has been continuous and substantial. A great deal of actual experimental data is now to hand and the author has therefore entirely re-written the original volume, so that this book is practically a new one.

The author has undoubtedly, in his former position of chief of drainage investigation, U.S. Department of Agriculture, had the opportunity of a better training in land drainage work than is usual. This book, which is partly the result of that experience, is without question the best treatise on drainage engineering to be found to-day. The only criticism which appears justified, in a casual analysis of the book, is that the author has not abandoned the old formulae for flow in pipes and ditches, which have been, to a great extent, abandoned by engineers. The use of these formulae gives results for flow greatly in excess of actual gaugings.

Drainage assessments are discussed in Chapter XVI. very clearly and concisely. Brief chapters are included on Levee Drainage Systems, Reclamation of Tidal Land, Drainage of Irrigated Lands, Drainage of Peat and Muck Lands, and Control of Hill Waters.

This volume, while perhaps too small to be considered a thorough treatise on the question of land drainage, will be found to be a most valuable one to the engineer interested in this work.

Modern Sanitary Engineering.—Part I., House Drainage. By Gilbert Thomson. Published by Constable & Co., Limited, London. Cloth; size, 5¾ x 8¼ in.; 260 pages, 110 illustrations. Price, $1.60.

Of the numerous books on the above subject most have been written from the tradesman's point of view. At the same time many engineering problems are involved in the collection, conveyance and disposal of sewage. This volume deals specially with house drainage. Very few books are to be found which are based on general principles, and which lead from these to practical applications. This present treatise is based on a course of lectures on Sanitary Engineering delivered by the author in the Civil Engineering Department of the Royal Technical College, Glasgow. The book will be found to be a most invaluable one for the engineer interested in the sanitation of individual houses.

PUBLICATIONS RECEIVED.

Bridges Over Navigable Rivers.—Some practical considerations, by C. E. Smith. Being Vol. 14, No. 150, Bulletin of the American Railway Engineering Association. E. H. Fritch, secretary, 900 South Michigan Avenue, Chicago.

Institution of Civil Engineers of Ireland.—Being the transactions of the 76th section, November, 1911, to May, 1912. P. F. Purcell, honorary secretary, Dublin.

Map of City of Calgary.—Harrison & Ponton, engineers and surveyors, Calgary, Alta., forward copy of their latest revised map of the city of Calgary. Copies may be secured by addressing their office, Calgary.

Winnipeg Hydro-Electric Power Station.—Being a description of the Winnipeg hydro-electric power station, reprinted from "Engineering," July 26-Aug. 2, 1912. Vickers, Limited, of Sheffield, England, Canadian office, 20 Bleury Street, Montreal, will forward copies on request.

Text Books and Industrial Works.—The Canadian Engineer (Book Department), 62 Church Street, Toronto, have issued a new catalogue of text books and industrial works. Copies may be secured by addressing the Book Department, Canadian Engineer.

Rail Steel Concrete Reinforcement Bars.—Standard specifications for the above. Copies may be secured from the secretary of the American Steel Manufacturers' Association, address J. J. Shuman, c/o Jones & Laughlin Steel Company, Pittsburg, Pa.

Tide Tables for the Pacific Coast of Canada, for the year 1913. Issued by the Tidal and Current Survey, Department of the Naval Service, Dominion of Canada. Mailed free on request.

Tide Tables for the Eastern Coast of Canada, for the year 1913. Issued by the Tidal and Current Survey, Department of the Naval Service, Dominion of Canada. Mailed free on request.

Summary Report of the Mines Branch, Department of Mines, for the calendar year ending December 31st, 1912. Copies may be secured from Eugene Haanel, Director, Mines Branch, Department of Mines, Ottawa.

Weights and Measures, Gas and Electricity. Being Part 2 of reports, returns and statistics of the inland revenues of the Dominion of Canada for the year ending March 31st, 1912. Deputy Minister of Inland Revenue, Ottawa.

Sea Fisheries of Eastern Canada. Being the proceedings of a meeting of the Committee on Fisheries, Game and Fur-Bearing Animals of the Commission of Conservation, held at Ottawa, June 4th and 5th, 1912. Copies may be secured from the secretary, Commission of Conservation, Ottawa.

Report of the State Commission of Highways. Being the annual report of the State of New York for 1911. C. Gordon Reel, Superintendent of Highways, Albany, N.Y.

Supplement to the Annual Report of the State Engineer and Surveyor of the State of New York, for the fiscal year ending September 30, 1911. Being a report of the Bureau of Hydraulics, Department of the Barge Canal, comprising the 12th annual report on Steam Gauging. John P. Newton, assistant engineer, Albany.

Annual Report of the City Engineer of Toronto, for 1911. R. C. Harris, Commissioner of Works and City Engineer, Toronto, Ont.

Mine Fires. A preliminary study. By Geo. S. Rice. Being Technical Paper No. 24. Joseph A. Holmes, director, Bureau of Mines, Department of the Interior, Washington, D.C.

Mechanical Properties of Red Wood. By A. L. Heim. Being Circular 193, Forest Products Laboratory Series.

Henry S. Graves, Forester, Forest Service, U.S. Department of Agriculture, Washington, D.C.

A Study of Iowa Population. As related to industrial conditions. By John E. Brindley. Being Bulletin No. 27, Engineering Experiment Station, Iowa State College of Agriculture, Ames, Iowa.

Road Legislation and Administration in Iowa. By John E. Brindley. Being Bulletin No. 28, Engineering Experiment Station, Iowa State College of Agriculture, Ames, Iowa.

Some Fallacies and Facts Concerning Engineering Work in Great Britain. By W. A. Martin, late assistant general manager of the Toronto Electric Co. Being a reprint from The Canadian Engineer issues, August 8th and 15th, 1912. Copies may be secured from the Canadian British Engineering Co., Limited, Toronto.

◆

CATALOGUES RECEIVED.

Rubber Insulated Wire and Cable.—The Standard Under-Ground Cable Co., of Canada, Limited, Hamilton, Ont., forward copy of their pamphlet entitled "Sterling Rubber Insulated Wire and Cable." This is an artistic little publication, describing the manufacture of the Standard Under-Ground Rubber Insulated Wire and Cable.

Fire-Proof Houses.—The National Fire-Proofing Company, Fulton Building, Pittsburg, forward the sixth edition of their "Fire-Proof Houses of Natco Hollow Tile and How to Build Them." The book is distributed gratis to architects, but a charge of twenty cents is made to the general public.

Electrically Welded Wire.—The Clinton Wire Cloth Co., of Massachusetts, forward copy of catalogue describing their "Clinton" electrically welded wire fabric for reinforcing concrete construction. The catalogue is a most artistic one and gives many illustrations of the use of Clinton wire.

Beatty Hoists.—Messrs. M. Beatty & Sons, of Welland, Ont., forward their last catalogue describing their steam and electric hoists. The bulletin shows illustrations of their hoisting engines, centrifugal pumps, derricks, dredges, scows and clam shell buckets.

Briquetting Machinery.—The United States Engineering Company, 80 Wall Street, New York City, forward brochure on briquetting machinery, illustrating and describing briquetting machinery for coal, coke and ore products, as manufactured by William Johnston & Sons, Limited, of Leeds, England, for whom they are the representatives.

Water Filtration.—The Loomis-Manning Distributing Company, 828 Land Title Building, Philadelphia, forward their catalogue describing the Loomis system of filtration, pressure or gravity. They also enclose a reprint of the December issue of Dun's Review, in which in every building mentioned in an article on "The Rebuilding of New York," the Loomis filter plant had been specified by the architects and engineers.

Metal Windows.—Henry Hope & Sons, Limited, 45 King Street West, Toronto, Ont., forward copy of Hope's Catalogue of Metal Windows. This is a magnificently bound and illustrated volume, 10 x 15 inches in size and containing about 200 pages. Typographically, the book is above criticism, and is in every way a most artistic publication.

Taylor Stokers.—The American Engineering Company, of Philadelphia, forward a pamphlet entitled "Facts Concerning the Operation of Taylor Stokers Obtained from the Users." The results of a number of tests are given in which the Taylor stoker was tried out. There are a number of interesting charts, and the tests themselves are of considerable interest.

Hayward Buckets.—The Hayward Company, 50 Church Street, New York, forward copy of their pamphlet No. 596, entitled "Hayward Buckets and Digging Machinery."

Transits and Levels.—Iszard-Warren Company, 136 No. 12th Street, Philadelphia, Pa., forward catalogue describing their "Sterling" transits and levels.

Grout Mixers.—The Ransom Concrete Machinery Company, Dunellen, N.J., forward pamphlet entitled "The Use of Ransom-Canniff Grout Mixers."

Machinery and Supplies.—The Chicago Builders' Specialty Co., Room 450, Old Colony Building, Chicago, Ill., U.S., forward their catalogue No. 35, illustrating their machinery and general contractors' supplies.

Electrical Apparatus.—Ferranti, Limited, Hollinwood, Lancashire, England, through their Canadian representative, G. C. Royce, 1688 Dundas Strees, West Toronto, forward their latest revised catalogue illustrating their switchboard instruments, switch gear and accessories, transformers, etc.

◆

HOLLINGER FINANCIAL STATEMENT.

The provisional statement of the company's finances, as on October 26th, 1912, is as follows:—

Assets and Liabilities.

Current Assets—			
Cash on hand and in Imperial Bank			$ 33,496.44
Bullion on hand			27,570.00
Bullion shipped (not paid for)			89,498.65
Gold precipitates on hand			97,500.00
Gold in mill solutions			24,000.00
Gold in slags on hand			17,000.00
Materials and supplies on hand			30,659.54
Accounts receivable			7,407.30
Guarantee Deposits			500.00
Imperial Bank, Toronto, reserve for dividend No. 1			90,000.00
Insurance paid in advance			2,832.41
			$ 420,464.34
Capital Assets—			
Mining properties		$2,500,000.00	
Developments		302,556.24	
Plant		593,728.09	
			$3,396,284.33
			$3,816,748.67
Current Liabilities—			
Wages			$ 18,254.00
Salaries			2,750.00
Accounts payable			36,972.86
			$ 57,976.86
Capital Liabilities—			
Capital stock			$3,000,000.00
Surplus, made up as follows, viz.:			
Premium on shares sold invested in plant and development		$250,000.00	
Profits from operations			
Reinvested in plant	$ 82,432.92		
Reserve for Dividend No. 1	90,000.00		
Balance in reserve	336,338.89	508,771.81	
			758,771.81
			$3,816,748.67

The above figures are provisional, and are subject to correction after actual returns from smelters are received. It is estimated that the surplus on November 2nd will amount to approximately $800,000.00

COAST TO COAST.

Halifax, N.S.—The management of the Provincial Exhibition has not, so far, proved a financial success. The deficit for the past season amounts to $10,500—about $400 less than last year.

Port Arthur, Ont.—There are now on the streets of the city about two thousand lights and this number will be considerably augmented next year as the lighting system is extended to the outlying sections.

Calgary, Alta.—The weather has been most favorable for contracting work during the past few weeks and several builders are taking advantage of the same and rushing through their several contracts.

Regina, Sask.—The demand on the power house for the past six years and the estimated demand for 1913 are given as follows: 1907, 833,039 kw.; 1908, 986,237 kw.; 1909, 1,201,160 kw.; 1910, 1,567,631 kw.; 1911, 2,458,535 kw.; 1912, 4,179,948 kw.; 1913, 7,000,000 kw.

Quebec, Que.—The Canadian Northern Railway Atlantic liner "Royal George," which was stranded on the rocks in the south channel off Point St. Lawrence, Island of Orleans, was released and floated into deep water at 4 o'clock Saturday afternoon, an hour before extreme high water.

Sydney, C.B., N.S.—The town of Sydney has witnessed an expenditure of about $600,000 in new buildings in the last ten months, and has also increased in population to an extent which makes the erection of more houses a necessity. This is another evidence of general progress in the lower provinces.

Calgary, Alta.—Grading has been started on the C.P.R. cut-off from Bassano to Swift Current at the Bassano end. Work is in progress as far as Empress, the new C.P.R. townsite, 120 miles east of Bassano. At the present time 30 miles of the road is in operation from the Swift Current end, and grading is being rapidly pushed to cover the 100 miles between that point and Empress.

Bassano, Alta.—It is reported that the C.P.R. intend making application for the approval of a route map of the Swift Current cut-off from Bassano to the forks of the Saskatchewan, 118 miles east. The new line practically parallels the Red Deer River and it is probable that Bassano will be made the divisional point. The new line leaves the main line 2½ miles east of Bassano and goes in a slightly northeasterly direction as far as the forks of the Saskatchewan.

Montreal, Que.—The newspapers of this city are giving considerable publicity to a scheme calling for the erection of an immense cathedral. A sum of about $2,000,000 has been offered for two churches now standing in the business section, and there is talk of this money being accepted and applied to the erection of the larger building. St. George's Church and Christ Church Cathedral (Anglican) are the buildings mentioned in this connection.

Calgary, Alta.—The total work completed on the various civic utilities for the year makes a considerable amount. According to the statement prepared by the engineering department and submitted to the commissioners the following are the totals for the year: Sewers, 277,375 feet; waterworks, 208,737 feet; sewer manholes, 627; water connections, 2,552; sewer connections, 2,604; sidewalks, 1,238,660 square feet; curb and gutter, 148,049 lineal feet; conduits, 337.

Ottawa, Ont.—Through the Minister of Justice, Hon. C. J. Doherty, the Canadian Government has filed objections before the International Joint Commission, now in session at Washington, to the proposed construction of an international dam at Kettle Falls, the outlet of Rainy Lake, on the Minnesota-Manitoba boundary. The government protested that the dam would affect the levels of the Lake of the Woods, which are now a matter of arbitration between the two governments.

London, Ont.—Mackenzie & Mann, it is announced, have asked that two proposals concerning the London and Port Stanley Railway be presented to the City Council immediately. Mayor Graham has arranged for a conference between C.N.R. representatives and members of the London and Port Stanley board, to be held next week. The proposition is creating much interest, especially in view of the fact that Hon. Adam Beck has just brought forward his scheme for the electrification of the road for municipal operation at a cost of $890,000. This latter scheme is to be voted on by the ratepayers of the city.

Montreal, Que.—The new building by-law, which has been in process of preparation for some time past by a committee of experts, of whom Messrs. J. Venne and W. J. Francis are members, has been submitted to the chairman of the special committee. It will be submitted to the city council, whence it will be sent to the Quebec Legislature for sanction. It is stated that the most sweeping recommendations include provision for preventing the spread of fire in factories, the introduction of smoke-proof towers for factories and schools, and the installation of efficient fire escapes. The report as submitted covers 213 closely typewritten pages, comprising 1,000 clauses. We hope in the very near future to submit an abstract of the by-law in these columns.

Niagara Falls, Ont.—The Queen Victoria Park Commissioners discussed the decision of the Privy Council recently confirming their right to collect rentals for excess power on the peak load system of measuring the electric current. It is now likely that the commissioners will at once exercise the power vested in them by the decision of the Privy Council, before which body this case has been pending for the past three years. Although the commissioners are disposed to favor the application of the Ontario Power Company for permission to install unit No. 13, the matter was left over for a conference between members of the power company and the park commissioners, to take place at Toronto in the near future. The plans submitted by the Electrical Development Company for a proposed machine shop were not acted upon, but the plans for a stairway leading to the transformer house at the summit of the hill were approved.

Province of Ontario.—A sanitary investigation of international waters from the St. Lawrence to the head of Lake Superior is to be carried on during the next year by the joint action between the Canadian and United States health authorities. The decision to extend the examination of boundary waters for evidence of pollution is the result of the suggestion made by the International Joint Commission at Washington last week. The waters to be examined include the Rainy River, St. Mary's River, River and Lake St. Clair, Detroit River, Niagara River, the St. Lawrence, Lake Superior in the neighborhood of Fort William, Port Arthur and Duluth, Lake Huron in the neighborhood of Saginaw Bay, Sarnia and Port Huron, the west end of Lake Erie around Port Stanley and Cleveland, and Lake Ontario near Toronto, the mouth of the Niagara River and around Rochester and Kingston. The Provincial Board of Health will have charge of the investigation of Ontario waters, and will do all the analytical work necessary.

Vancouver, B.C.—The report of the Northern Pacific for the year ended June 30th, 1912, shows that during the past three years terminal property at Vancouver has been bought in the interest of the Northern Pacific and the Great Northern, and is now being developed. When the plans now under consideration are completed there will be a first class terminal for both freight and passenger business owned jointly by the two companies. New station buildings were put up during the year and increased facilities provided at a number of places in Minnesota, in North Dakota, in Montana, in the State of Washington, and in Oregon. During the year 175 bridges were replaced and three abandoned, 111 bridges, 19,234 ft. in length, were replaced by timber structures, and seven permanent and 57 timber structures were replaced in permanent form. Of these, 46 were replaced by embankments and 18 were replaced by truss, girder, I-beam and reinforced concrete trestle, a total of 20,717 lineal feet, 119 timber culverts were rebuilt, 15 in temporary and 104 in permanent form. There are now under construction on operated lines 1,145 lineal feet of steel girder and I-beam spans; 870 lineal feet of steel truss spans; 1,408 lineal feet of reinforced concrete trestle; one 425-ft. double-track steel draw span and one 191-ft. movable leaf bascule span; also one steel highway viaduct, 738 ft. long.

Edmonton, Alta.—City commissioners of Edmonton, Alta., have called for tenders on 400,000 square yards of a total of 511,533 square yards of street paving to be laid the coming year. The estimated cost is $1,734,786. Tenders will be opened on December 10, a day after the civic election. The plans call for 422,643 square yards of paving on the north side of the Saskatchewan River, and 88,893 square yards on the south side, formerly known as Strathcona. This does not include all the work to be done during 1913. It is simply the paving that has been petitioned for to date. The city is holding in reserve 111,533 square yards of paving for the municipal-owned plant to be built next year. The largest amount of work on one street is 47,531 square yards in Nelson Avenue, between First and Twentieth Streets. Others range from 4,189 to 28,531 square yards. Most of the forty-one streets affected will have more than 10,000 square yards of pavement. Four of the streets lead toward the country. Among these are the Fort Saskatchewan and St. Albert trails, Stoney Plain Road and Namayo Avenue. Namayo Avenue, formerly the southern portion of the trail to Athabasca Landing, will be paved as far north as the Grand Trunk Pacific tracks. Although provisions may later be made to pave First Street to Alberta Avenue, at the present time the plans show a pavement to Norwood Boulevard about a mile.

◆

ONTARIO GOOD ROADS ASSOCIATION.

The executive of the above held a meeting in Toronto on Wednesday, November 20th last to discuss several important matters, among which was the proposal of a convention. It was resolved that an exhibition and convention should be held in the Machinery Hall of the Canadian National Exhibition, Toronto, February 26th-28th next. At this exhibition various road building and improving machinery will be demonstrated and different varieties and qualities of road sections will be on view. The first day will be devoted to the engineer, another day will be given to country roads and the other to town and city roads. Special facilities will be arranged whereby delegates will be able to attend the convention and hear the various speakers with comfort, it being decided to partition off a section of the building for this purpose. Major T. L. Kennedy, president of the association, and Vice-president N. Vermilyea were appointed to represent the association at the American Road Builders' Association, to be held December 3rd in Cincinnati. Mr. George Henry, Oriole, Ontario, is on a committee appointed to secure a permanent secretary.

The constitution of the association has been altered in order that all associations interested in improved roads may be represented at the February convention.

EFFECT OF METERS ON WATER CONSUMPTION.

The statistics given in the accompanying table are a concrete example of the effect of meters on consumption, and should commend itself forcibly to all citizens, in that it proves conclusively the fact that to meters more than to any other factor credit is due for checking wilful or neglectful waste of water. The figures are taken from the annual report of the Water Department of Houston, Texas. A pumpage of 141 gals. per capita in 1907 has been reduced to 53 gals. per capita to-day without depriving any person of this essential element. Dire results were predicted by fearful people just four years ago when the meter system was proposed, but to-day those who were formerly antagonistic are firm believers in this plan of delivering water to consumers.

Effect of Meters on Water Consumption, Houston, Texas.

Year.	Number of meters.	Percentage of consumers metered.	Average per capita pumpage.	Population city census.
1907	108	1.5 %	141 gals.	73,017
1908	303	4.0	122 gals.	79,464
1909	1,903	21.0	106 gals.	82,542
1910	4,556	48.0	82 gals.	95,930
1911	8,131	82.0	53 gals.	109,594

A total of 2,125,981,520 gals. of water was pumped as reported by the Chief Engineer for the year 1911, as compared to 2,859,091,610 gals. for the year previous. This represents a saving of 733,110,090 gals., notwithstanding several large conflagrations which occurred during 1911.

This fact deserves more than casual notice, as it is an economy that means more to the city than is represented in mere figures. It is a supply of pure water held in reserve for future use, insuring at the same time a lease upon the practical capacity of the wells for a greater period of time.

◆

BRANCH MEETING.

At a joint conference held recently in the city of Victoria, B.C., between representatives of the Vancouver and Victoria branches of the Canadian Society of Civil Engineers, it was decided to hold a convention in Victoria in the early part of December at which subjects of interest to the profession will be discussed and plans prepared for a demand upon the government for legislation at the coming session of the legislature in order to protect the interests of the Canadian engineers. Chief among the demands to be made upon the government will be one asking that as far as possible positions in the government service shall be confined to British subjects.

◆

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.

Mr. Benjamin E. Briggs, city engineer of Erie, Pa., was elected president of the American Society of Municipal Improvements at the annual convention in Dallas, Texas, November 13th to 15th. Messrs. Edward H. Crist, of Grand Rapids, Mich.; William A. Howell, of Newark, N.J., and A. F. MacCallum, of Hamilton, Ont., were elected vice-presidents; Mr. A. Prescott Folwell, of New York city, was re-elected secretary, and Mr. E. L. Dalton, of Dallas, Texas, treasurer.

PERSONAL.

W. E. STAVERT, of Montreal, Quebec, has been elected president and general manager of the Alaska Northern, to succeed O. G. Laberee, resigned.

WM. HALL has been appointed assistant trainmaster of the Grand Trunk with office at Hamilton, Ont., succeeding L. Harold, assigned to other duties.

A. F. MACCALLUM, C.E., city engineer of Hamilton, Ont., has been elected a vice-president of the American Society of Municipal Improvements. The society had their annual meeting, November 13th to 15th, at Dallas, Texas.

MR. R. A. SARA, B.A.Sc., has resigned his position as assistant business manager of the Winnipeg power department and will return to his home in Toronto in order that he may become connected with the Hydro-Electric Commission in that city. He is a '09 graduate of Toronto University in electrical and Mechanical engineering.

DONALD M. McINTYRE, K.C., solicitor of the city of Kingston, who has recently been appointed chairman of the Ontario Railway and Municipal Board, is a native of Kingston and has lived there practically all his life. He is a graduate in Arts of Queen's University, and was called to the bar in 1885 with honors, obtaining the gold medal. He served as alderman in the city council from 1889 to 1905, except during 1892, when he was elected as mayor. In 1895 Mr. McIntyre was appointed city solicitor, in which office he has served to date. For many years he has been a trustee of Queen's University, a governor of the School of Mining, and is at present chairman of the Board of Governors of the School of Mining. He is a governor of the Kingston General Hospital, of which board he was chairman for the year 1904 to 1905. Mr. McIntyre is a member of the Frontenac Club and of the Kingston Golf and Country Club. He is a junior member of the law firm of McIntyre & McIntyre, practising in Kingston. As chairman of the Ontario Railway and Municipal Board he will be brought more intimately in touch with the engineering profession than in the past, and we therefore wish Mr. McIntyre every success in his new work.

Mr. Donald M. McIntyre, K.C.

MR. THV. HEYERDANL, chief engineer for the Canadian Office of Escher Wyss & Company, Zurich, Switzerland, is severing his connection with the company, and will leave Canada shortly. Mr. Th. Seidl, previously in charge of the engineering department of the London office of Escher Wyss & Company, has been appointed as Mr. Heyerdanl's successor.

R. F. PACK, general manager of the Minneapolis General Electric Company, formerly general manager of the Toronto Electric Light Company, has been appointed a member of the Smoke Prevention Committee of the Minneapolis Civic and Commerce Association.

DR. WILLIAM M. MACKAY, M.E., of the Reserve Mines, C.B., has been appointed Senator by the Canadian Government. Dr. MacKay has been interested in engineering contracting for many years.

NATHANIEL CURRY, of Amherst, N.S., has been appointed to the Senate by the government. Mr. Curry is president of the Canada Car and Foundry Company, Canadian Steel Foundries, Limited, and the Rhodes, Curry & Company, Limited. He is also a director in the Canadian Light and Power Company, Canada Cement Company and a number of other companies. He was born in Kings County, N.S., in 1851.

CHAS. L. DUNFORD, late of the city engineer's office, Toronto, was recently appointed assistant city engineer of London, Ont. After seven years' experience in England, Mr. Dunford came out to Canada and joined the firm of Ross & Holgate, consulting and supervising engineers, Montreal. After being with them for two years, he left to superintend the construction of a new and modern factory for the Standard Drain Pipe Company, of St. Johns, Que., and later some building work for the same firm in New Glasgow, Nova Scotia. He joined the main drainage works (Toronto), in November, 1908, and worked on the trunk sewer system, disposal works, Ashbridge's Bay improvement and grade separation schemes, and in 1910 visited England and reported to Mr. Chas. H. Rust (at that time city engineer) on several of the largest disposal works in England. Shortly after Mr. A. C. D. Blanchard's appointment as city engineer of Lethbridge, Mr. Dunford changed from the main drainage works to the sewer department, where he worked on the storm overflow sewer system, and was for some months resident engineer on the Carlaw Avenue storm overflow sewer. Later he worked with Mr. R. R. Knight on the combined sewer system for West Toronto, from which work he resigned to take up his new duties.

MR. J. S. MacLACHLAN, of Victoria, B.C., has been appointed resident engineer of federal public works on Vancouver Island. Mr. MacLachlan is a graduate of the Royal University, Dublin, and has been in Canada since the early part of 1911.

JOHN W. WATSON has been appointed as head of the accounting and purchasing department of the Works Department of Toronto by Commissioner R. C. Harris, and the appointment has been sanctioned by the city council.

◆

OBITUARY.

MR. CHARLES W. LEONARD, of London, Ont., died at his home in that city recently. He was a member of the firm of E. Leonard and Sons, London, Ont., manufacturers of engine boilers and other heavy sheet iron products.

◆

IMPERIAL DRY DOCK COMPANY.

The proposed steel plant and shipbuilding industry at East St. John is practically assured. Messrs. Norton Griffiths and Company have acquired the charter of the Imperial Dry Dock Company, and are negotiating with the city and the provincial and federal governments to guarantee the sinking funds on its bond issues, in establishing an immense plant beside the dry dock. They will also ask the federal government to agree to the enlargement of the dry dock to a length of 1,150 feet, which it is said would make it the largest in the world. It would be necessary to reclaim 200 acres near the dry dock to be the site of the steel plant and ship yards. The fullest confidence is expressed in St. John that this great industry will be established.

APPEAL FOR THE HOSPITAL FOR SICK CHILDREN.

Mr. J. Ross Robertson, chairman of the trustees of the Hospital for Sick Children, Toronto, has written to The Canadian Engineer, asking that the needs of this institution be brought to the attention of our readers.

In his letter he states: Last year we treated 1,294 in patients, and 341 of these came from 218 places in Ontario. I feel that no more worthy cause can be presented for generous public support.

Any reader wishing to contribute toward the upkeep of this worthy cause may send his contribution to Mr. Douglas Davidson, Secretary-Treasurer of the Hospital, Toronto.

COMING MEETINGS.

CANADIAN SOCIETY OF ENGINEERS.—Mechanical Section Meeting will be held in the rooms of the Society, 413 Dorchester Street West, Montreal, December 5th, 1912. Chairman, H. H. Vaughan.

NATIONAL ASSOCIATION OF CEMENT USERS.—December 12th to 18th. Annual Convention, Pittsburgh, Pa. President R. L. Humphrey, Harrison Building, Philadelphia, Pa.

UNION OF MANITOBA MUNICIPALITIES.—Programme for Ninth Annual Convention to be held in Convention Hall of the Industrial Bureau, Winnipeg, Nov. 26, 27, 28, 1912. Secretary, Reeve Cardale, Oak River, Man.

AMERICAN WOOD PRESERVERS' ASSOCIATION.—Ninth Annual Convention will be held at Chicago Jan. 21-23, 1913. Secy-Treasurer, F. J. Angier, Mount Royal Station, B. & O. R. R., Baltimore, Md.

AMERICAN INSTITUTE OF CONSULTING ENGINEERS.—Annual Meeting, January 14th, 1912, will be held at The Engineers Club, 32 West Fortieth Street, New York, N.Y. Secretary, Eugene W. Stern, 103 Park Avenue, New York.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. Secretary, E. L. Power, 150 Nassau St., New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annua Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving: Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh B. Fergusson, 911 Rogers Building, Vancouver, B.C. Headquarters: University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayo Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.: Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose: Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.: Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION. President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. B. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only, unless otherwise noted, at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
12-10—400,000 sq. yds. Asphalt and Bitulithic Pavement, Edmonton, Alta.	(P. & S.)	11-21

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

TENDERS.

Collingwood, Ont.—The contract for the erection of the rifle range at this point has been awarded to Mr. John Stockton at a contract price of $5,512.

London, Ont.—Sealed proposals addressed to the "Chairman and Members of No. 2 Committee," will be received at the office of the city clerk until 5 p.m. on Thursday, November 28, 1912, for the construction of tile sewers on (1) Queen's Place; (2) Burwell Street, between York and King Streets, London, Ont. Plans and specifications covering the above mentioned works may be seen at the office of the city engineer.

Long Branch, Ont.—The contract for the construction of the Rifle Ranges at this point have been let by the Department of Public Works, Ottawa, to Mr. A. T. McMaster for the price of $13,400.

Louiseville, P.Q.—R. C. Desrochers, secretary Department of Public Works, Ottawa, will receive sealed tenders up to 4 p.m. on Monday, December 9th, 1912, for the erection of public buildings in this municipality. Plans, specifications and form of contract can be seen and forms of tender obtained at the post office, Louiseville, P.Q., at the office of Mr. H. N. Lymburner, superintendent of Public Buildings, 103 St. Francois Xavier Street, Montreal, P.Q., and at the above Department.

Monteith, Ont.—Mr. John Critchley, Monteith, Ont., will receive sealed tenders up to 9 p.m. Saturday, December 14th next, for the erection of a frame school house in this municipality. Specifications may be seen at the post office, Monteith.

Ottawa, Ont.—J. D. McLean, assistant deputy and secretary, Department of Indian Affairs, Ottawa, will receive sealed tenders, marked "Tenders for Cape Croker Timber," until noon of Thursday, December 5th next; 400,000 feet of lumber, consisting of maple, beech, elm, basswood, ash and hemlock are required, which the Indians of Cape Croker are to take out during the ensuing winter and deliver on the shore of Lake Huron at convenient points for shipment.

The Crown dues payable to the Department on this timber are as follows: Maple and elm, $4 per M. ft., B.M.; beech and basswood, $3 per M. ft., B.M.; hemlock, $1, and ash $2 per M. ft., B.M.

Ottawa, Ont.—Messrs. William Kennedy and Sons, of Owen Sound, Ont., have received a contract from the Department of Public Works, for the supply of 16 heavy stop-log winches, at a cost of $297.90 each.

St. Joseph, N.B.—Sealed tenders addressed to Rev. B. LeClavalier, superintendent of St. Joseph's College, N.B., marked on the outside "Extension to College," will be received up to and including the 31st of December, 1912, for the construction of an ell to the existing college at St. Joseph, N.B.

The plans and specification may be seen at the office of R. A. Frechet, architect, 39 D'Aigiullon, Quebec P.O., or at the College, applying to the Rev. Superior.

Regina, Sask.—Tenders for the construction of power house, laundry and refrigerating plant, Regina General Hospital, will be received by the city commissioners up till noon of December 14, 1912. Full particulars may be obtained upon application to Wenger & Cockburn, Room 208, Aldon Block, 12th Avenue, Regina. (See advertisement in The Canadian Engineer).

Rocky Island Park, Alta.—Sealed tenders, addressed to the Deputy Minister, Department of the Interior, Ottawa, and marked on the envelopes "Tender for Dead Timber Permit," will be received at this department until noon on Thursday, the twelfth day of December, 1912, for permits to cut dead timber on the undermentioned parcels of land in the Rocky Mountains Park, Alberta. Each parcel must be tendered for separately.

Toronto, Ont.—Tenders will be received at the office of Frank Barber, civil engineer, 57 Adelaide Street East, Toronto, until noon of December 20th, 1912, for the erection of four steel bridges of 75 ft. clear span, in the county of Simcoe. Plans and specifications may be obtained at the office of the engineer. (See advertisement in Canadian Engineer).

Toronto, Ont.—Tenders for the several trades required in the erection of new school building on Lippincott Street, Toronto, will be received until noon of January 7th, 1913, by W. C. Wilkinson, secretary-treasurer of Advisory Industrial Committee. Full particulars may be obtained at the office of the architects, Messrs. Ross & MacFarlane, Room 506, 59 Yonge Street. (See advertisement in Canadian Engineer).

Toronto, Ont.—Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, up to noon on Tuesday, December

3, 1912, for the purchase and removal of two-story and basement dwelling at the corner of Severn Street and Rosedale Ravine drive.

Envelopes containing tenders must be plainly marked on the outside as to contents.

Specifications may be seen and forms of tender obtained at the office of the Commissioner of Parks, City Hall, Toronto.

Vancouver, B.C.—Separate tenders will be received by the undersigned up to 3 p.m. Wednesday, December 11th, 1912, for the following quantities of steel pipe: First—26,400 ft. of 6in. steel pipe, 6,600 ft. of 8in. steel pipe, 5,280 ft. of 12in. steel pipe. Second—52,800 ft. of 6in. steel pipe, 13,200 ft. of 8in. steel pipe, 10,560 ft. of 12in. steel pipe. Third—79,200 ft. of 6in. steel pipe, 19,800 ft. of 8in. steel pipe, 15,840 ft. of 12in. steel pipe. Specifications and blank tender forms may be obtained at office of James Stuart, city purchasing agent.

Winnipeg, Man.—Tenders for the manufacture, delivery and erection in the power house at Point du Bois, Man., of two units of horizontal shaft turbines and governors, and three units of horizontal shaft turbines and governors, will be received until noon of December 16th, 1912, by the chairman, Board of Control, Winnipeg. Full particulars may be obtained at the office of the city light and power plant, 54 King Street, Winnipeg. M. Peterson, secretary, Board of Control office, Winnipeg.

Winnipeg, Man.—The Board of Control, Winnipeg, will receive tenders up to November 28th, 1912, for furnishing electric supplies and line materials required during the year 1913. Particulars may be obtained at the office of the City Light and Power Department, 54 King Street.

Winnipeg, Man.—Sealed tenders addressed to the chairman, Board of Control, will be received at the office of M. Peterson, secretary, Board of Control, up to 11 a.m. on Monday, December 2nd, 1912, for the manufacture and delivery f.o.b. city yards, Winnipeg, duty paid, of one well drilling machine for waterworks wells. Specification and form of tender, together with conditions governing tenders as prescribed by by-law may be obtained at the office of the city engineer, 223 James Avenue.

CONTRACTS AWARDED

Elmira, Ont.—The contract for the Carnegie public library has been awarded to Emmanuel Martin. The contract figure is $6,500. Mr. Mahoney, of Guelph, is the architect.

Fredericton, N.B.—Carvell Bros. and McDonald, of Woodstock, N.B., have taken a sub-contract on the St. John Valley Railway. They are to build three miles of the road between this city and Woodstock.

Ladysmith, B.C.—The Ladysmith school board has awarded the contract for their proposed new school to Messrs. Smith & Adams. The contract price is $7,047, including hot water heating, and the school will be built according to plans prepared by S. B. Birds, whose design was chosen in a recent competition.

Moose Jaw, Sask.—The A1 Electrical Company of this city have received the contract for the supply of the electrical generators and fittings to be used in the new building of the Progress Laundry. It is the intention of the shareholders of the laundry to generate their own electrical energy for light, heat and power purposes.

RAILWAYS—STEAM AND ELECTRIC.

Province of Alberta.—The line of the recently formed Western Dominion Railway, which has been approved by Hon. Frank Cochrane, will run from the international boundary line northward through Cardston and Pincher Creek to Calgary, a distance of about 200 miles. As well there will be a branch from the main line breaking off near Pincher and running up along the south fork of the Old Man River to coal fields in the Rockies. The branch will be about 30 miles long. It is reported that J. P. Morgan and George J. Gould, of New York, are financing this enterprise.

Niagara District, Ont.—Work will be commenced on the Niagara-on-the-Lake extension of the Niagara, St. Catharines and Toronto Railway during the next few days.

Saskatoon, Sask.—It is expected that the street railway will be in operation about the middle of December.

Toronto, Ont.—Civic Controller Maguire is working up interest in a proposed belt line for North Toronto. The idea is a belt line with civic street cars running on it. Since Yonge Street is tied up by the Metropolitan Railway he would construct a highway five hundred feet west from Yonge Street and paralleling that thoroughfare from St. Clair Avenue to Bedford Park, thence along the northerly limits of that village, and returning via the parallel road east of Yonge Street and through Mount Pleasant Cemetery.

Vancouver, B.C.—The management of the British Columbia Electric Company will add 100 new passenger cars to the street railway system of this city during the next twelve months. The cost of this addition will be $800,000. Mr. F. R. Glover is authority for this statement.

LIGHT, HEAT AND POWER

Beaverton, Ont.—The ratepayers endorsed a by-law calling for the installation of hydro-electric power into this municipality.

Esquimalt, B.C.—Messrs. Taylor & Gunson, mechanical engineers, have been formally notified of their appointment by the council of Esquimalt to report upon the best methods to be adopted in the installation of an electric lighting system.

Galt, Ont.—A movement is under way for the lighting of 2½ miles of roadway between the boundaries of Galt and Preston.

Regina, Sask.—The municipal commissioners have recommended that the water pumps be separated from the power house and two individual departments created with a separate plant each.

St. Catharines, Ont.—The directors of the Niagara, St. Catharines and Toronto Railway will erect a large power house in this city. Mr. Seixas is general manager.

GARBAGE, SEWAGE AND WATER.

Coquitlam, B.C.—Messrs. Wilson, Lake and Bentall have prepared plans for a temporary waterworks system to be installed at once.

Hamilton, Ont.—The municipal council are seriously considering several proposed improvements to the water supply and water handling facilities of this city. It is proposed to construct a seawall one mile in length. A. F. MacCallum, City Engineer.

London, Ont.—Probably the item of most importance to be voted on by the ratepayers in the coming election is that of a debenture issue of $625,000 to finance the construction of a storm sewer. It is probable that the entire issue will not be floated at once as the city has been divided into sections in order that one section may be completed and financed each year. It has been suggested that the services of an engineer be secured to revise and check the plans now prepared.

BUILDINGS AND INDUSTRIAL WORKS.

Calgary, Alta.—The provincial government of Alberta will erect a $400,000 Normal School in this city.

Duncan, B.C.—The Department of Public Works, Ottawa, will erect a building to be used as a post office and Indian Agent Office, at a cost of $50,000. Mr. F. H. Shepherd, M.P., for Nanaimo, is responsible for this information.

Edmonton, Alta.—The municipal council will erect a three-story market building at a cost of $100,000. A. J. Latornell, city engineer.

Lethbridge, Alta.—Mr. John Taylor, of the Taylor Milling Company has enquired of the municipal council as to what terms could be arranged should he erect a large milling plant in this city.

London, Ont.—If a suitable agreement between the officials of this municipality and the directors of the London and Port Stanley Railway may be reached, a new hotel will

Section of Government Parkway, Ottawa, Canada, treated with Tarvia B.

The Property Owners' Investigation.

IN the City of St. Thomas, Ont., the property owners on Gladstone Avenue contemplate petitioning the City Council to improve the roadways. They commissioned one of their number to visit various American cities, inspect pavements and make a report. Their investigator, Mr. E. A. Horton, visited various cities in New York and New Jersey. In his report he made the following statements:

> "I saw a 'Tarvia X' road in Rochester which extends from the city to the lake front, a distance of about six miles. It had been in use for eighteen months, and when I saw it, it was in excellent condition, with heavy traffic over it every day. I........inspected a piece of road in Newark........the surface when finished was smooth, and to my mind was one of the finest pieces of road it was my privilege to see. We then inspected another piece of 'Tarvia X' which had been done by the Road Commission two years ago........Constant heavy traffic passes over this road every day, and trucks have loads of from 6 to 8 tons. Steel-tired drays were used with most of their heavy traffic. This piece of road, as I saw it, did not show any wear whatever, and was apparently in as good condition as when it was put down.
>
> "I did not confine my attention to Tarvia roads as I saw (here he mentioned five of the commonest types of road treatment) and every other kind of road that is known
>
> "I must say after making enquiries from people who were in no way interested, nor did they know I was seeking information, that everyone had a good word to say for the Tarvia road. I have no hesitation in recommending it for use on our street, and at the estimate cost that has been given us, after seeing the many pieces of road that I have seen, I think it is the cheapest road that can be built."

The foregoing is quoted from the St. Thomas, Ont., 'Journal of February 20th, 1912. Since that date Gladstone Avenue has been constructed with Tarvia X.

Anyone who will investigate the road problem with the same thoroughness will reach similar conclusions. Tarvia is made in three grades:

"Tarvia X" for use in constructing roads and pavements.

"Tarvia A" for hot surface applications.

"Tarvia B ' (applied cold) for dust prevention and road preservation.

Booklet describing the latest developments in methods for building tarviated roadways and pavements will be sent free on request. Address our nearest office.

THE PATERSON MANUFACTURING COMPANY, LIMITED
MONTREAL TORONTO WINNIPEG VANCOUVER
THE CARRITTE-PATERSON MANUFACTURING CO., LIMITED
ST. JOHN, N.B. HALIFAX, N.S.

be erected in this city. Col. Davidson is representing the company in the negotiations.

Medicine Hat, Alta.—Messrs. Christie and Cousins will erect a five story theatrical building in this city at a cost of $100,000.

Medicine Hat, Alta.—The Medicine Hat Pump and Brass Manufacturing Company will erect a factory in this city. Mr. Charles Crary is an official of this company.

Moose Jaw, Sask.—The Canadian Pacific Railway will erect a large car shop and make an addition to their yards in the western portion of this city.

New Westminster, B.C.—The directors of the Dominion Trust Company have ordered the preparation of plans for a large office building in this city. The structure is to be erected on Columbia Street at a cost of $200,000.

Preston, Ont.—Announcement is made of an amalgamation of the Metal Shingle and Siding Company of this place with the A. B. Ormsby Company, of Toronto, and the Canadian interests of the United States Metal Products Company, of New York. The new concern will go in for the manufacture of an improved line of sheet metal products.

Regina, Sask.—The management of the Bank of British North America will build an office structure in this city.

Regina, Sask.—It is reported that the management of the Garden City Feed Company, of Iowa, U.S.A., have secured a suitable site in this city for the erection of a branch warehouse.

Regina, Sask.—The executive of the Regina College have decided to commence work on two towers at a cost of $70,000.

St. John, N.B.—The municipal council will consider the matter of erecting a civic abattoir. W. F. Murdock, city engineer.

St. John, N.B.—The Dominion Tar and Chemical Company, of Sydney, N. S., are considering the establishment of a tar distillery in this city and have requested the municipal council for a suitable site.

Toronto, Ont.—It is reported that Ernest McConkey has secured financial assistance and will proceed with the erection of a twelve-story hotel near the corner of Bay and King Streets. If this project is carried through the site will be that recently acquired by the Dominion Bond Company and reported in the columns of this paper.

Watrous, Sask.—A report in The Canadian Engineer a few weeks ago announced that negotiations were under way for the location of a bottling plant at this point. Word has now been received that the matter has been completed and the interested parties will commence on the erection work. All kinds of soft drinks and the waters of Little Manitou Lake will be bottled.

Winnipeg, Man.—The management of the Winnipeg Tribune, a leading daily paper of this city, have purchased a block of ground on which to erect a new building.

BRIDGES, ROADS AND PAVEMENTS.

Galt, Ont.—The ratepayers of this town voted in favor of a debenture issue of $75,000 to improve the highways in and around this municipality.

Lindsay, Ont.—A deputation of prominent citizens visited Peterboro' recently in order that an examination of the concrete paving might be made. It was announced in this connection that there is a probability of considerable paving being done in Lindsay next spring.

Ottawa, Ont.—It is reported that a Good Roads Bill will come before the legislature at this session and if the same becomes law the subsidies to be awarded the various provinces will be as follows:—Alberta, $52,189.90; British Columbia, $54,669.52; Manitoba, $63,460.10; New Brunswick, $49,019.86; Nova Scotia, $68,576.90; Ontario, $351,466.64; Prince Edward Island, $13,059.70; Quebec, $279,964.80; Saskatchewan, $66,592.58.

Port Arthur, Ont.—The municipal board of works have recommended that all the streets in the inter-city park be macadamized and the council will prepare the preliminary estimates for 1913 in such a manner that funds for this work will be provided.

Province of Saskatchewan.—The report of the Highways Commissioners will be presented to the legislature at Regina in a few days, and will contain a very comprehensive account of the work carried on this year in connection with the building and improving of main roads throughout the province. An extensive scheme covering the whole province has been mapped out, and is being worked out as rapidly as possible.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending November 11th, 1912:—

An analytical chemist in Yorkshire wishes to secure the co-operation of a capable firm in Canada for the introduction to the Dominion market of a new black waterproof enamel or varnish which is his specialty.

A London publisher, wholesale and export bookseller, is open to undertake the representation of a Canadian firm of wood pulp manufacturers.

From the branch for city trade inquiries, 73 Basinghall Street, E.C.

A London firm desire the addresses of Canadian producers and shippers of antimony gold ores.

CURRENT NEWS.

Calgary, Alta.—The council are taking steps to have an investigation commenced into the alleged exorbitant charges for natural gas. The corporation council will investigate the city's power to probe this matter, and upon his report the council will act.

Dunnville, Ont.—Mr. Charles Ross has located a four-million-foot gas well near this point. The Buffalo and Dunnville Oil and Gas Company holdings, controlled by Buffalo capital, adjoins the property on which this strike was made.

Fredericton, N.B.—Mr. J. H. Grisdale, director of the Experimental Farm system, has approved of the plans for the farm to be established near this city and the sum of $60,000 will be spent in order to have the place in working condition as soon as possible.

Kingston, Ont.—The municipal council has recommended the purchase of an auto fire engine and the electors will be requested to vote authorization for a debenture issue to cover cost of the same.

London, Ont.—There is a large list of money by-laws to be submitted for the opinion of the ratepayers, and it is probable that the list will be enlarged. At the present time the specific items are as follows:

Electrification of the London and Port Stanley Railway	$ 890,000
Federal Square	250,000
Storm sewer, total	625,000
Loans to industries	81,000
Sanatorium grant	15,000
Schools for 1913	80,000
Schools for next five years, additional	320,000
	$2,261,000

London, Ont.—The ratepayers will vote on a by-law calling for the appropriation of $250,000 to be used in the making of a federal square.

Montreal, P.Q.—A large block of vacant land between Longueuil and St. Lambert has been acquired by certain real estate interests and announcement is made of their intention to erect a model village thereon.

Province of New Brunswick.—It is the intention of the New Brunswick Government to establish two agricultural colleges in the province, one at Woodstock and the other at Sussex.

Ottawa, Ont.—The civic waterworks enquiry is officially closed and the presiding judge will present his report before the council at an early date.

Ottawa, Ont.—The Railway Commission will be asked to give a new hearing to the matter of agreements between the Bell Telephone and Independent Telephone Companies. This is a much vexed question, the Railway Board, under the chairmanship of the late Judge Mabee, having ruled on it

about a year ago. It was then thought the question was settled, but the companies have again disagreed, and consequently the matter will be re-opened before the commission.

Ottawa, Ont.—Public works main estimates this session will provide about $10,000,000 for harbor improvements next season at St. John, N.B., Quebec, Toronto, Port Arthur, Vancouver and Victoria. The new terminal scheme at Halifax will be looked after by the railway department, while the Montreal harbor improvements are financed under special arrangement with the harbor board.

Preston, Ont.—The ratepayers endorsed a by-law granting a loan and building site to the Anchor Bedding Company, of Toronto. This company will erect a branch factory at once. The management of this firm consists of Harvet S. Coombs, Thomas Coombs and A. W. Martin.

Windsor, Ont.—The committee dealing with the selection of an auto fire engine does not propose to purchase until a public demonstration of two engines is held in this city.

THE J. C. WHITE COMPANY.

J. G. White & Co., Inc., of New York City, announce the formation of the J. G. White Engineering Corporation and the J. G. White Management Corporation, the former to take over the engineering and construction departments and the latter to take over the operating department. The parent company will continue to handle financial matters. Under this arrangement it is anticipated that greater efficiency will be obtained in the conduct of the increasing volume of engineering and construction work of the company and in the operation of its properties. The J. G. White Engineering Corporation has an authorized capitalization of $2,000,000, one-half of which is preferred stock and one-half common. All of the common stock will be issued to J. G. White & Co., Inc., and $500,000 of the preferred stock, the remainder being reserved for future requirements. The J. G. White Management Corporation has an authorized capitalization of $1,000,000, one-half being preferred stock and one-half common. All of the common stock will be issued to J. G. White & Co., Inc., and $350,000 of the preferred stock, $150,000 of the latter remaining unissued for future requirements. A meeting of the stockholders of the parent company will be held on December 10 to take final action on this plan, which is recommended by the directors.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

17992—November 11—Authorizing C.P.R. to divert (1) highway adjoining North Boundary, Sec. 11, Tp. 24, R. 20, W. 4 M., in North-Easterly direction, (2) highway adjoining North Boundary, Sec. 12, Tp. 24, R. 20, W. 4 M., in N.W. direction, (3) highway adjoining West Boundary, Sec. 12, in N.W. direction to connect with (1); and (4) to construct, by grade crossing, across First St. E. (1), and across road allowance proposed to be closed, all within Townsite of Hussar, Alta.

17993—November 12—Authorizing C.P.R. to construct Kerrobert-Northeasterly Branch across 15 highways, mileage 02.63 to 35.45.

17994—November 12—Authorizing city of Vernon, B.C., to extend Lyons Street across the C.P.R.

17995—November 12—Approving plan of rearrangement of siding necessary from G.T.R. and C.P.R. into Exhibition Grounds, West Toronto.

17996—November 12—Authorizing Kettle Valley Ry. to open for traffic the portion of its railway from Merritt easterly 29 miles.

17997—November 12—Directing C.L.O. & .W. (C.P.R.) to construct livestock pass for Norman Bellyou, Trenton, Ont., in Lot 6, Con. 1, Township of Murray.

17998—November 12—Directing M.C.R. to install a Hoeschen electric bell at crossing of highway 1 mile east of Shedden, Tp. of Southwold, Ontario.

17999—November 15—Authorizing C.P.R. to open for traffic new second track, St. Constant to St. Claude, mileages [illegible] to 26.6.

18000—November 13—Directing C.P.R. to demolish or remove baggage room at Farnham, Que., from its present site, before June 1st, 1913.

18001—November 13—Authorizing C.P.R. to construct sidings for Davenport Coal Co., S.W. ¼, Sec. 12, Tp. 7, R. [illegible], W. 5 M., at Burmis, Alberta.

18002—November 13—Authorizing C.N.R. to construct across C.P.R. in city of Moose Jaw, Saskatchewan.

18003—November 11—Approving C.N.R. Plan "B" showing structures to be erected at crossing of Park Road, Manitoba St., and 2nd and 3rd crossings of Moose Jaw Creek.

18004—November 13—Approving location C.N.O.R. station grounds at Fitzroy Harbor, Tp. Fitzroy, Co. Carleton, Ontario.

18005—November 13—Authorizing C.N.O.R. to construct across Con. Road between Cons. 9 and 10, Station 1784.40 and Side Road between Lots 20 and 21, Con. 10, Station [illegible], Tp. Fitzroy.

18006—November 12—Authorizing C.N.O.R. to construct across public road between Lots 343 and 350, Parish St. Leonard de Port-Maurice, Co. Hochelaga, Quebec.

18007—November 13—Approving location James Bay and Eastern Ry., station grounds at Dufferin, Tp. Dufferin, Que., mileage 30.7, from Roberval; and rescinding Order No. 16341, dated April 10th, 1912.

18008—November 14—Authorizing G.T.P. Branch Lines Company to construct Prince Albert Branch across highway in S.E. ¼ Sec. 4, Tp. 33, R. 27, W. 2 M., mileage 1.5, Rural Mun. No. 312, Sask.

18009—November 11—Authorizing G.T.P. Branch Lines Company to construct Moose Jaw-Northwest Branch across Twenty-two (22) highways, mileage [illegible] to mileage [illegible].

18010—November 13—Authorizing G.T.P. Branch Lines Company to construct Calgary-Boundary Branch across Eight (8) highways, in Dist. South Alta., Alta., mileage 82.5 to 90.3.

18011—November 9—Authorizing Niagara, St. Catharines and Toronto Railway to construct across Carlton and Niagara Sts., in Lot 14. between Cons. 4 & 5, Tp. Grantham, Co. Lincoln, Ont.

18012—November 14—Varying Order No. 16816, dated June 25th, 1912, to provide that Bartlett Ave., be maintained at grade, over C.P.R. & C.N.O.R. in North Toronto; that Ossington Ave. and Christie St. subways be constructed with 14 ft. clear headway; that Albany Ave. be not re-opened, and Huron St. not opened across said lines, but that Bridgeman Ave. be opened and graded through to Bathurst Street.

18013—November 12—Extending, until May 1st, 1913, the time within which C.P.R., equip all rolling stock in use by it of 37 ft. or over in length, or weighing 35,000 lbs. or more, with power brakes, to be approved by the Board.

18014—November 8—Directing C.P.R. to file, within 30 days from date of this Order, plans of gates directed to be erected at McTavish St., Fort William, Ont., and operated by a day and a night watchman.

18015—November [illegible]—Directing C.P.R. and G.T.R. to protect, from 6.30 a.m. to [illegible] p.m. daily by a watchman, crossing at George Street, Toronto, Ontario.

18016—November [illegible]—Refusing application of T. H. & B. Ry. to cross, at grade, the highway as Stanford Ave., Hamilton, Ontario, with two branch lines or spurs.

18017—November [illegible]—Directing T. H. & B. Ry. to protect by a day and a night watchman, crossings at O'Reilly St., and Ferguson Avenue, Hamilton, Ontario.

18018—November 14—Approving location C.P.R. proposed station at Severn Falls, on Lot 22, Con. 7, Tp. Matchedash, Co. Simcoe, Ont.

18019—November 13—Authorizing C.P.R. to construct spur for the [illegible] Furniture Co., Ltd., Calgary, Alberta.

18020—November 14 Authorizing C.P.R. to construct cross-over track opposite the V.V. & E. Railway & Navigation Company's freight sheds, to connect with G.N.R. New Westminster, B.C.

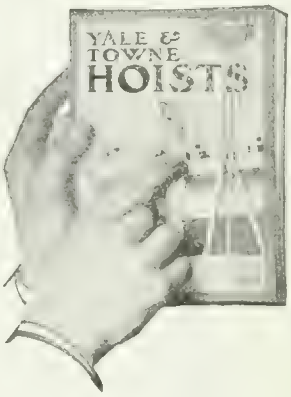
18021—November 14—Approving revised location G.T.P. Branch Lines Company Tofield-Calgary Branch in Sec. [illegible], Tp. [illegible], R. [illegible], W. 4 M.

18022—November 15—Authorizing G.T.R. to construct siding for the Canada Furniture Manufacturers, Ltd., Wiarton, Ont.

18023—November [illegible]—Authorizing Oshawa Railway Company to construct branch line from end of present track on Bruce Street, town of Oshawa, Ont., to property of "Brick Limited," and to cross C.N.R., and Toronto and Eastern Ry. Companies' tracks.

THE TRIPLEX BLOCK

REASONS FOR SENDING TODAY FOR THIS BOOK.



Triplex Block built into a 10-ton geared trolley and used for loading on floats lying alongside a pier in New York City.

A Book on the Handling of Loads, the Latest Practice Here and Abroad.

The change is coming fast. Modern plants today are equipping throughout to give each workman easy mastery over any load up to 20,000 lbs.

The new practice is to reduce all loads to one-man manageable loads, from the raw material coming in to the completed material going out. This frees the factory from an enormous waste. The primitive way of pitting time-paid muscle against stubborn weight, soon costs any manufacturer who stands for it a fortune in wages and restricts his output.

Months of research were spent by Yale and Towne engineers to make this book cover a wide range of conditions, so the man who sends for it will find it the most practical and helpful book that ever came to his desk.

Send for a free copy now, before
the thought is out of your mind.

Triplex Blocks { **16 Sizes:** One-fourth of a ton to forty tons.
9 Active Stocks all over Canada.

Every Block Tested to Fifty Per Cent. Overload.

The Canadian Fairbanks-Morse Co., Limited

MONTREAL, ST. JOHN, OTTAWA, TORONTO, WINNIPEG,
CALGARY, SASKATOON, VANCOUVER, VICTORIA.

18024—November 15—Recommending, to the Governor-in-Council for sanction, the agreement of amalgamation of the Western Dominion Ry. Co., and the Alberta Pacific Ry. Co.

18025—November 15—Approving Nipissing Central Ry. Co.'s Standard Passenger Tariff C.R.C. No. 8; company to publish same with a copy of this Order, in at least two consecutive weekly issues of "The Canada Gazette."

18026—November 15—Authorizing C.P.R. to take, for the construction of a business siding at Leslie Station, certain lands in Gore of Puslinch, Tp. Puslinch, Co. Wellington, Ont.

18027—November 15—Authorizing C.P.R. to open for traffic its Moose Jaw-Northwesterly Branch from Rosetown to Conquest, mileage 128.21 to mileage 162.57, distance of 34.3 miles.

18028—November 16—Authorizing C.P.R. to construct bridge No. 50.0, Cascade Subdivision, British Columbia Division.

18029—November 15—Authorizing C.P.R. to open for traffic Wilkie-Northwesterly branch from mileage 0 to mileage 27.8, in Province of Saskatchewan.

18030—November 15—Authorizing C.L.O. & W. (C.P.R.) to construct across five (5) highways in town of Bowmanville, Ont., from mileage 148.46 to mileage 149.20 (from Glen Tay).

18031—November 15—Authorizing C.L.O. & W. (C.P.R.) to construct across, by means of overhead bridge, road allowance between Lots 28 and 29, Con. B, Tp. Brighton, East Riding, Co. Northumberland, Ont., mileage 95.25 from Glen Tay.

18032—November 13—Directing G.T.R. to construct subway at highway leading to Cardinal, Ontario.

18033—November 14—Authorizing G.T.R. to construct siding for the Standard White Lime Co., Ltd., on Lot 18, Con. 2, Tp. of North Oxford, near Beachville, Ont.

18034—November 15—Authorizing C.N.R. to construct across thirty-eight(38) highways in the Province of Saskatchewan, on its Thunderhill Branch.

18035—November 15—Authorizing C.N.O.R. to construct across public road between Lots 32 and 33, Con. 15, Tp. Ferris, Dist. Nipissing, at Station 846.54, mileage 224.74.

18036—November 15—Authorizing C.N.R. to construct across public road between Secs. 10 and 15, Tp. 65, R. 22, W. 4 M., by overhead structure.

18037—November 15—Authorizing Kettle Valley Ry. Co. to construct across highway at Station 383.57, northwest of Penticton, B.C.

18038—November 15—Authorizing C.P.R. and G.T.P. to operate their trains, without first being brought to a stop, over crossing at mileage 6.1, Sec. 6, Tp. 39, R. 19, W. 3 M., Saskatchewan.

18039—November 14—Amending Order No. 17628, dated September 30th, 1912.

18040—November 11—Dismissing application of G.T.P. and G.T.P. Branch Lines Co., for an order relieving them from erecting gates in openings in right-of-way fences provided to give the public ingress to and egress from station reservations on their respective lines.

18041—November 12—Dismissing application of Rockwood, the town of Stonewall, and the Stonewall Dist. Board of Trade, for an order directing the C.P.R. to grant commutation passenger tickets to passengers travelling between Winnipeg and Stonewall.

18042—November 11—Dismissing complaint of the Board of Trade of city of St. Boniface, Man., and Messrs. Couture and Marion against C.P.R., alleging excessive charges on brick from St. Boniface, Man., to Yorkton, Sask.; also discrimination in favor of brick manufacturers of Portage la Prairie.

18043—November 11—Refusing application of Midland Ry. Co., of Manitoba, and Winnipeg Trackage, Ltd., for an Order granting leave to the Midland Ry. Co. to cross a main industrial spur of C.P.R. near Wall St., Winnipeg, with additional spur to the Winnipeg Trackage, Limited.

18044—November 11—Granting leave to C.N.R. to construct across C.P.R. in S.E. [illegible] Sec. [illegible], Tp. [illegible], R. [illegible], W. 4 M., Alberta.

18045—November 11—Amending Order No. 17216, dated August 15th, 1912, by providing that the overhead structure authorized by said Order be wide enough to permit of 2 tracks only to pass under the same; that this order is made without prejudice to the right of C.P.R. to apply at any future time for an Order for G.T.P. Branch Lines Co. to erect, at its own expense, a structure of sufficient width to permit of four tracks passing under same.

18046—November 11—Authorizing C.P.R. to construct one additional track and re-construct existing track on its Emerson Branch; and that it place, at its own expense, a watchman at Montcalm St., St. Boniface, Manitoba.

18047—November 11—Directing C.N.R. to file with the Board within thirty days from this date plans showing a four-car siding between Baldur and [illegible], Manitoba.

18048—November 11—Directing that the Municipality of North Norfolk, Man., be added as a party to the application of Robert Wallace et al, for a subway between Secs. 24 and 25, Tp. 11, R. 12, W. P. M., Manitoba, and that the road be diverted by the C.P.R.

General Order No. [illegible]—November 11—Providing specifications for maintenance of signals at highway crossings.

18049—November 12—Remitting penalties imposed under Order No. 16823, dated June 20th, 1912; and directing the city of Montreal to commence construction of subway under C.P.R. at Park Ave., not later than April 1st, 1913, and complete same by October 1st, 1913.

18050—November 15—Authorizing Kettle Valley Ry. Co. to carry freight traffic from Midway to Carmi, B.C., distance of 46 miles.

18051—November 18—Approving by-law No. [illegible] of Niagara, Welland and Lake Erie Ry. Company, authorizing C. J. Laughlin, Jr., Vice-President of the Company, or H. Rooke, Secretary, to prepare and file tariffs for freight and passenger traffic and of telegraph tolls.

18052—November 18—Authorizing the Government of the Province of Saskatchewan to construct road north of Secs. 13 and 14, Tp. 22, R. [illegible], W. 3 M., Saskatchewan.

18053—November 18—Approving revised location of site of the Burrard Inlet Tunnel and Bridge Co., bridge from the high-water mark south of Burrard Inlet, to high-water mark north of Burrard Inlet, also width (225 ft. each) of opening spans of bridge across the Second Narrows of Burrard Inlet; and rescinding Order No. 17565, dated September 24th, 1912.

18054—November 18—Authorizing M.C.R. to construct sidings across and upon certain highways in Tp. Crowland, and over and upon Lots 25 and 26, Con. 7, Tp. Crowland, Co. Welland, Ont.; and approving lateral and overhead clearances shown on plan.

18055—November 15—Relieving M.C.R. from providing further protection at crossing of Ferry Road, just west of Victoria Park Station, Niagara Falls, Ontario.

18056—November 18—Authorizing Nipissing Central Ry. Co. to open for traffic its line from Haileybury to New Liskeard.

18057—November 20—Establishing collection and delivery limits, by the Dominion Express Company, in town of Woodstock, N.B.

18058—November 18—Establishing collection and delivery limits for the Dominion Express Company, in the town of Wolfville, N.S.

18059—November 18—Authorizing C.N.Q.R. to construct across public road on Lot 27, Parish of St. Monique, Co. Two Mountains, Quebec.

18060—November 19—Authorizing C.N.O.R. to construct across public road between Cons. B and 2, Tp. Westmeath, Co. Renfrew, Ont.

18061—November 19—Approving proposed location C.N.O.R. station grounds at Desaulniers, Tp. Gibbons, Ont., mileage 265.5.

18062—November 15—Approving location C.N.R. through Tps. 7-11, and Rgs. 2-6, W. P. M., Manitoba, mileage 18.08 to mileage 53.76.

18063—November 19—Authorizing G.T.P. Branch Lines Co. to construct its Prince Albert Branch across highway in N.W. ¼ Sec. 3, Tp. 48, R. 26, W. 2 M., mileage 104.7, Saskatchewan.

18064—November 16—Authorizing G.T.P. Saskatchewan Ry. Co. to construct Weyburn-Branch across C.P.R.'s Weyburn-Lethbridge & Soo Branches, Sec. 20, Tp. 8, R. 14, W. 2 M., at Weyburn, Sask.

18065—November 16—Authorizing G.T.R. to construct two sidings for A. S. Nicholson, on part of Lot 11, village Burlington, Ont.

18066—November 18—Authorizing G.T.R. to construct siding for the John Carey Lumber Co., Ltd., on Lot 22, town Lindsay, Ont.

18067—November 19—Authorizing G.T.R. to construct siding for the Dain Manufacturing Co., Ltd., Tp. Humberstone, Co. Welland, Ont.

18068—November 19—Authorizing G.T.R. to construct siding for the National Concrete Mfg. Co., on Lot 18, Con. 4, Tp. Ops, Co. Victoria, Ontario.

18069—November 20—Authorizing C.P.R. to construct additional track across 4 highways, mileages 16.0 to 23.0, Swift Current Subdivision, Saskatchewan Division.

18070—November 18—Relieving C.P.R. from providing further protection at highway known as "Chemin de la Cote St. Elzear," 0.94 miles west of St. Martin Jct., Quebec.

18071—November 18—Approving revised location C.P.R., Sudbury-Sault Ste. Marie Branch, as now constructed from mileage 20.73 to mileage 21.40, Webbwood Subdivision.

18072—November 18—Relieving C.P.R. from providing further protection at Tilson Ave., town of Tillsonburg, Ontario.

18073—November 16—Authorizing C.P.R. to construct two spurs for the C. H. Wentz Lumber Co., Saskatoon, Sask.

18074—November 16—Authorizing C.P.R. to construct two industrial spurs for city of Calgary, Alta.

18075—November 19—Authorizing C.P.R. to construct bridge No. 2.65 on its Eastern Division, Prescott Subdivision, Ont.

18076—November 19—Authorizing C.P.R. to construct two spurs for the Superior Elevator Co., Ltd., Fort William, Ontario.

18077—November 16—Authorizing C.P.R. to construct spur for the Great West Saddlery Co., Calgary, Alberta.

18078—November 2[illegible]—Amending Order No. 17958, dated Nov. 8th, 1912, by striking out the words, "no one appearing for said land-owners in objection thereto," and substituting therefor the words, "and the property-owners affected."

18079—November 18—Extending, until May 31st, 1913, the time within which C.P.R. complete work to be done at highway crossing on Lot 18, Con. 7, Tp. Peel, at mileage 35.7.

18080—November 18—Authorizing C.P.R. to divert highway adjoining North Boundary, Sec. 24, Tp. 32, R. 19, W. 3 M., mileage 194.03, Moose Jaw Northwesterly Branch.

18081—November 19—Authorizing C.P.R. to construct additional track across 18 highways, mileages 105.6 to 124.04, Moose Jaw Subdivision, Saskatchewan Division.

18082—November 20—Authorizing C.L.O. & W. (C.P.R.) to construct across road allowance between Lots 22 and 23, Broken Front Con. of Tp. Clarke, Co. Durham, Ont., mileage 140.58 from Glen Tay.

18083—November 19—Authorizing C.L.O. & W. to construct bridge No. 87.8 across Ontario St., and C.N.R.'s spur, Trenton, Ont.

18084—November 18—Authorizing C.L.O. & W. to construct bridge at mileage 159.3, at Oshawa, Ontario.

18085—November 19—Authorizing C.L.O. & W. to construct across road allowance between Lots 33 and 34, Con. 1, Tp. Darlington, Ontario.

18086—November 19—Authorizing C.L.O. & W. to construct across road allowance between Lots 24 and 25, Broken Front Con., Tp. Darlington, Co. Durham, Ontario.

18087—November 11—Directing C.N.R. to install gates, to be operated by a day and a night watchman, at Gore St., Fort William, Ont.; said gates to be in operation by March 1st, 1913.

18088—November 21—Postponing, until and including December 31st, 1912, the effective date of cartage tariff of Wabash R.R.

18089—November 20—Authorizing G.T.R. to operate cars and engines, jointly with T. H. & B. Ry., upon and over siding of Standard Underground Cable Co., of Canada, at Hamilton, Ontario.

18090—November 21—Authorizing C.P.R. to construct spur for Hunter Structural Steel Co., Toronto, Ontario.

18091—November 21—Authorizing C.P.R. to construct spur for the Superior Match Co., Ltd., Owen Sound, Ontario.

18092—November 21—Authorizing C.P.R. to construct spur for G. A. Abbott, Lot 15, Con. 2, Tp. North Orillia, Co. Simcoe, Ont., mileage 71.5, Port McNicoll Subdivision.

The Canadian Engineer

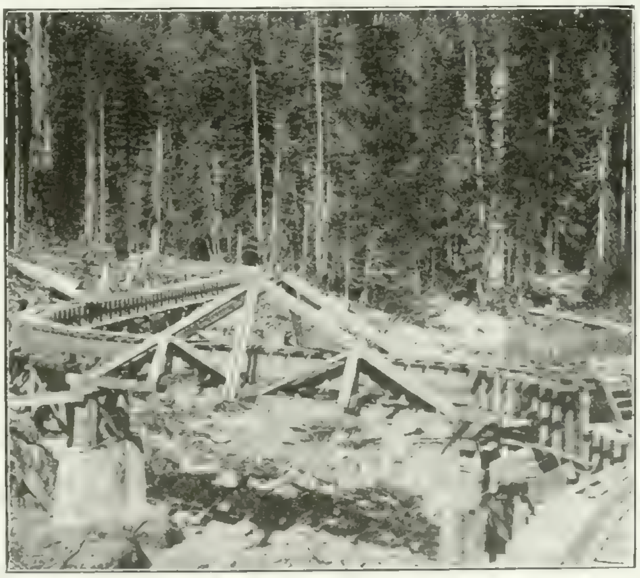
An Engineering Weekly

THE VANCOUVER ISLAND POWER COMPANY, LIMITED JORDAN RIVER DEVELOPMENT.

PART II.

The flume traverses a heavy belt of timber along the entire route, and the clearing necessary for adequate protection of the structure was very extensive. A wide clearing was made, all trees being taken down along the upper side which would reach the flume in falling, and all leaning and dead trees were cut along the lower side.

The fallen timber was hand-logged down the hill from the zone to be occupied by the flume proper and the flume railway, and the loppings and branches, as far as the season would permit without danger, were piled and burned as the work went forward. About 6,000,000 feet, board measure, of timber were cut in making the clearing.



Junction of "Y" Creek Flume With Main Flume.

The flume box, which is designed for an ultimate carrying capacity of 175 cubic feet per second, is 6 x 6 feet in size, and has a grade of one foot to 1,000 feet. It is supported by bents spaced 15 feet centre to centre, set upon ample footings, either of cedar blocks or concrete, according to the nature of the underlying material, the maximum bearing upon a square foot of the supporting ground surface being not greater than one ton. The sizes and dimensions of the different members of the flume are as follows:—

2 Bent posts	Cedar	8″ x 8″	battened
1 Cap	Fir	8″ x 8″	gained
2 Stringers	Fir	6″ x 14″	lapped
6 Sills	Fir	4″ x 8″	gained
12 Box posts	Fir	4″ x 6″	
6 Yokes	Fir	4″ x 6″	gained

The box is of fir and spruce planking, 2 inches thick, 12 inches and 18 inches wide, and surfaced on one side, with flat battens, ½″ x 3½″, nailed over the cracks.

Side planks to carry 75 cubic feet of water per second have been installed, and additional planks may be added as greater capacity is required, at which time intermediate bents, or at least supporting posts will be installed at the middle points of the stringers, reducing the span to 7½ feet. In the construction of the flume 3,500,000 board feet of lumber were used, to supply which, a saw mill was erected at the lower end of the flume and adjacent to the forebay reservoir. The capacity of the mill was about 30,000 board feet per day, and the equipment included machinery for surfacing, sizing, gaining and trimming the flume lumber for erection with a minimum of hand labor.

The total amount of lumber cut in the mill for the entire construction work was about 6,000,000 feet, board measure.

To facilitate the construction of the flume, a 36-inch gauge railway, with 30-lb. rail, was built parallel to the flume along its entire length, and at an elevation about 15 feet above it. Lumber and other material for the flume, as well as for the diverting dams and storage dam, were delivered over this track, which connects directly at its lower end with an inclined tramway of the same gauge. This inclined tramway begins at a landing wharf on the shore, is two miles in length and after overcoming a difference of elevation of 1,200 feet, connects with the flume railway near the saw mill.

The operation of the inclined tramway is accomplished by means of a powerful haulage engine placed at the upper end of the tramway, and a second and lighter haulage engine near the lower end, slight grades at sections preventing the cars from overhauling the cable by their own weight.

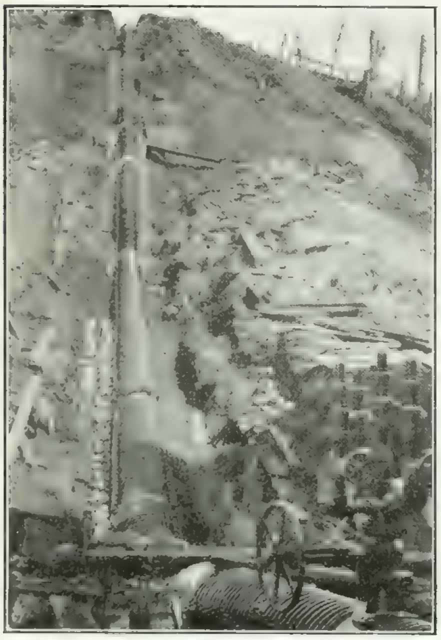
In building the flume, all members were sized and cut to true length, including bent posts, and all daps and gains were made at the saw mill by machine. The footings were accurately located and placed to elevation with transit and level, somewhat in advance of the erection; the length of the posts required for each bent was determined, and the information forwarded to the framing yard at the saw mill where the various parts were prepared. In this way, confusion and crowding was avoided on the work, and a greater rate of progress made possible.

The system worked out quite satisfactorily, very few errors occurring in the process.

Five combination sand and waste gates are provided along the length of the flume at approximately equal intervals, and a standard weir was built at the lower end where several measurements were taken to determine the carrying capacity with different depths of water. The results of these tests indicates a value of about 122 for the coefficient in Chezy's formula: $v = c \sqrt{rs}$.

The flume has been in continuous operation since November, 1910, and has proven tight, safe, and reliable in every respect, only one short interruption having occurred, due to the loss of one bent destroyed by a small landslide.

Forebay Reservoir.—The forebay reservoir site consists of two small, gently sloping, heavily wooded depressions leading in opposite directions from a low saddle or ridge, lying 1,150 feet above sea-level. Two earth dams were built across the valleys, the material for the embankments being all excavated from the higher ground between. Each embankment is about 35 feet in height, and 1,000 feet in length. The total volume of fill in the two dams is 35,000 cubic yards.



Pipe Line at Entrance Power House.

The material available for the embankments was semi-cemented gravel, or hardpan, which required drilling and blasting to loosen. A double-sheathed timber diaphragm of cedar planking, connecting with a concrete cut-off wall sunk well into the impervious hardpan, was installed in each dam to insure water tightness, the material from which the dams had to be built not being sufficiently impervious to make them adequately water-tight without diaphragms.

Dam No. 1 was built with wheelbarrows and heavy sleds, hauled with a donkey engine, and hoisted and dumped from an overhead cableway. Dam No. 2 was built under contract, with horses and carts.

No particular attempt was made on either embankment to puddle or compact the material during construction, except that a limit of three feet was placed upon the layers deposited, and a small amount of puddling with water was done immediately in front of the timber diaphragms.

A concrete intake structure, surmounted by a structural steel gate tower, from which were operated two roller bearing 54-inch hydraulic sluice gates, was erected inside the reservoir at the head of the pipe line. Two 44-inch steel riveted pipes are installed through the base of the south dam. From the intake structure to the core wall, the pipes are imbedded in a reinforced concrete casing, and from the core wall to the lower toe of the dam, two open culverts, with common centre wall, and roofed with reinforced concrete slabs, are installed around the pipes, insuring perfect drainage, and allowing access for inspection. Two 6-inch standpipes extending up to the floor of the gate tower are installed at the upper end of the pipes.

The reservoir, when full, covers an area of about 12 acres, and the capacity available—4,800,000 cubic feet—is sufficient to operate the single generating unit installed for a period of about 30 hours. To prevent damage to the slopes from wave action, a light timber boom is floated about four feet from the water's edge, and braced at intervals from the bank.

An emergency spillway with flash boards and apron is built in the solid ground at the east end of dam No. 2.

The function of this forebay reservoir is to increase the peak load capacity of the power plant by liberal storage immediately at the head of the pipe line; and also to furnish a reserve supply of water to run the plant for a considerable period in event of accident to the flume line.

Pipe Line.—The pipe line leading from the forebay reservoir to the power station is 9,800 feet in length, and follows a gentle slope for the greater part of its length, the lower 300 feet descending abruptly to the power house. The upper third of the length of this line is designed to deliver water for two generating units of 4,000 kilowatts each, and consists of one riveted steel pipe 44 inches diameter, ¼ inch to ⅜ inch plate. At the lower end of this section a cast-iron "Y" piece, fitted with two 36-inch cast steel gate valves is installed, providing for the extension of two lines to the power house. The lower section of the pipe is designed to deliver water for one generating unit only, and the single line installed consists of lap-welded steel, with riveted roundabout joints, in approximately equal lengths of 36-inch, 34-inch, 32-inch and 30-inch diameter, and varying in thickness from 5/16 inch at the "Y" end to 9/16 inch at the lower end.

The pipe line was designed with an ample factor of safety according to current practice in the extensive use of lap-welded pipe. However, owing to the apprehension aroused in the minds of the officials of the company by a reported failure of a similar lap-welded pipe elsewhere, the lower end of the pipe line for a distance of 2,200 feet was reinforced by one inch round steel bands, after the manner of a wood-stave pipe with spacing from 3¾ to 4 inches.

Several hours after first filling the line with water the 36-inch valve on the dead end at the "Y" burst without warning and the water in the 44-inch pipe above was suddenly discharged. No damage, however, resulted to the pipe line, ample air openings having been provided for its protection. The valve was split almost centrally through the body and bonnet, the lower half being blown a distance of 20 feet away. An investigation of the design of the body showed that an ample section of metal had been provided throughout for a large factor of safety and no flaws or other defects were disclosed. The valve had been ordered tested before shipment, but this had not been done. The accident emphasizes the unreliability of cast-iron, even for moderate pressures. The cast-iron valve bodies were then discarded, and cast-steel parts installed in their places, and, as an additional precaution, two expansion joints, one in the 44-inch pipe above the "Y" and one in the 36-inch pipe below, were introduced in the line to eliminate any strains due to expansion or contraction to which the cast iron parts might be subjected. Eight 4-inch air valves and 4 manholes were installed along the length of the pipe, and immediately back of the power house a cluster of four automatic pressure relief valves was mounted.

Concrete anchor bolts and supporting piers were erected at proper intervals along the pipe line.

The inclined tramway was installed parallel to the line along its entire length, from which the pipe and other materials were delivered.

The entire pipe line installation, including the furnishing of material and the erection, was done under contract by the Jens Orten Boving Company, Limited, of London, England.

Power Station.—The power station faces the ocean and is erected on low ground at the foot of the pipe line hill, which slopes very abruptly for the lower three hundred feet of its length. The ground surface is elevated only slightly above extreme high-tide elevation, but the waterwheel nozzles are placed 5.5 feet above the maximum high-tide level. A very heavy growth of cedar, spruce and hemlock timber was removed from the site in preparation for the construction work.

The power house building is 49 feet by 97 feet, sufficient space being provided for the installation of two complete generating units, with exciters, transformers, switchboards, low-tension and high-tension switches, etc. Concrete and steel were used exclusively in the construction of the building, account being taken in making the location for its extension to contain an ultimate installation of four generating units.

The pipe line previously described enters the power house at the back and is connected to the generating unit through a 24-inch gate valve, there being an effective head of 1,100 feet. The water is controlled by a needle regulating nozzle in conjunction with an auxiliary needle nozzle, the needle of which is mechanically connected to the main needle and is so arranged that it opens automatically as soon as the main needle closes rapidly or beyond a certain predetermined point. In this way the auxiliary nozzle maintains a sufficient vent to avoid a dangerous rise of pressure in the pipe line. The auxiliary nozzle is also fitted with an independent slow-moving adjustable time element mechanism which gradually closes the nozzle when the main needle stops moving, thus conserving the water supply.

A Lombard, Type Q, oil pressure governor is used for speed regulation and is directly attached to the main nozzle needle.

The main generating unit consists of a 4,000 kilowatt generator and a 6,000 horse-power impulse water-wheel. This unit is of the two-bearing type, having the revolving field of the generator mounted on the shaft between the bearings and the water-wheel overhung at one end. The speed is 400 revolutions per minute.

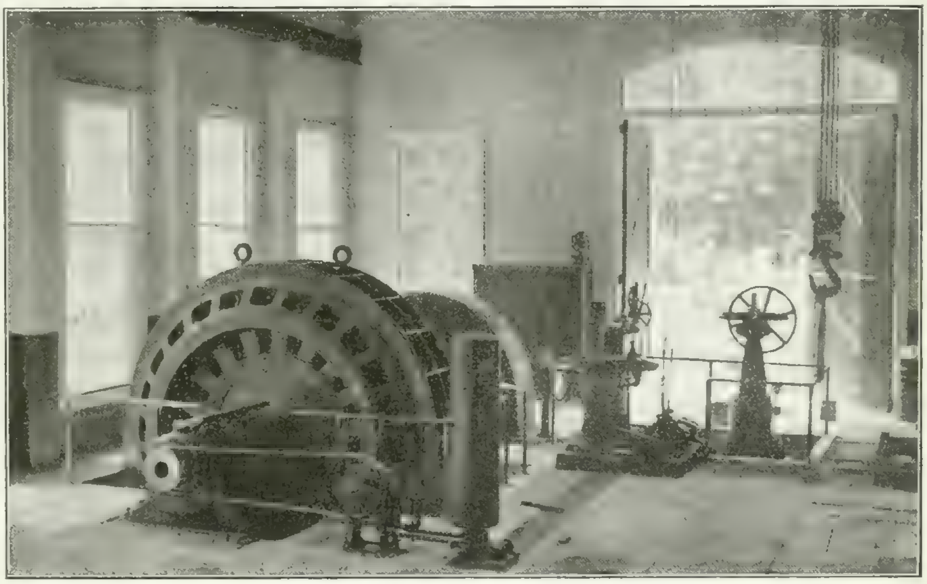
One exciter is installed which has sufficient capacity to supply maximum field current for two generating units. The extended shaft carries on one end an overhung impulse water-wheel, and is connected at the other end to an inductor motor, which operates at the generator voltage, and has sufficient capacity to drive the exciter generator continuously. The exciter water-wheel is equipped for hand control only, as the motor serves as a speed regulator and no governor is necessary.

A four-panel marble switchboard, provided with a complete equipment of instruments and controlling devices, including Tirrell regulator, is mounted on the switchboard floor, which is elevated about 6 feet above the generator floor.

The current delivered by the generator at 2,300 volts is stepped up to 40,000 volts by means of three 1,400 kilowatt-ampere oil-insulated water-cooled transformers, which are installed in fire-proof compartments back of the generator. These transformers are now operating with delta connection, delivering current to the transmission line at 40,000 volts. This voltage will be raised upon the installation of the second unit to 60,000 by changing the delta connection to star connection with grounded neutral.

The water-wheel equipment was furnished by the John McDougall Caledonian Iron Works, Limited, of Montreal, and manufactured under the Doble patents; the generator and exciter by the Allis-Chalmers-Bullock Company, Limited, and the transformers, switchboards, switches and lightning arresters by the Canadian General Electric Company, Limited.

A 75,000-volt three-pole oil switch with disconnecting switches, and arranged for hand operation from the generator floor, is installed in the high-tension room. A complete equipment of three-phase aluminum cell, 40,000-volt lightning arresters has been provided to protect each end of the transmission line.



View of Inside of Power House.

At Victoria the sub-station used in connection with the operation of the transmission line from the old Goldstream hydro-electric station has been utilized. Extensive alterations were made in the old building, including the erection of transformer stalls for two banks of transformers, and high-tension switch-room of reinforced concrete, space being provided for bringing two transmission circuits into the building.

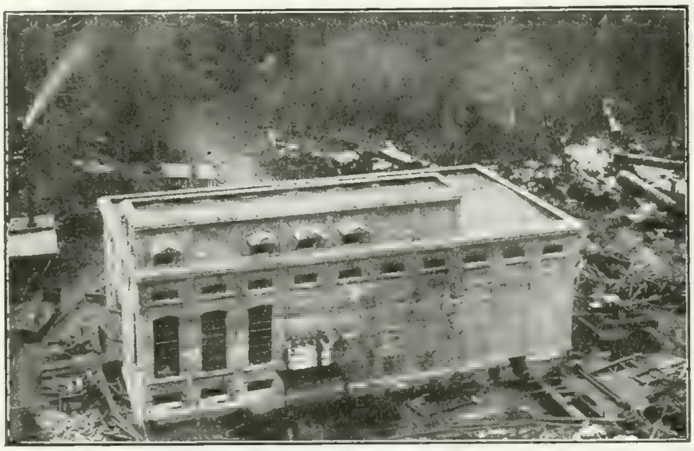
An unfortunate and very unusual set of conditions were encountered in the power station foundations, the remedying of which was fortunately taken in hand in time to prevent serious delay in putting the plant into operation.

In the construction of the building and the setting of foundation, unusual precautions were observed; the excavation for the foundation walls and the machine settings were carried to a depth of about 21 feet below the floor level. Some seams of peat, varying in thickness from 2 inches to 2 feet, were encountered. At the bottom of the trench a fairly stiff, blue, sandy clay was found, into which borings were made for a distance of 12 feet, showing the same class of material throughout this distance.

Tests of the bearing power of the ground were made, which showed that a load of five tons per square foot would not cause any settlement.

Having taken these precautions in predetermining the bearing power of the soil, it appeared that this material was entirely safe for foundation purposes with the load to be imposed.

After the building was completed observations taken indicated that a slight settlement was taking place. These observations were continued for several months in order to establish beyond a doubt that the building and machinery foundations were actually settling, and to determine as nearly as possible the rate of settlement.



View of Rear of Power House.

In June, 1911, a series of test holes were put down at points around the building, which showed that a soft muck bed from 5 to 15 feet in thickness lay some 50 feet below the floor level, and about 25 feet below the bottom of the foundations. The layer of clay on which the foundations were set had been stressed beyond its supporting power, and had gradually compressed the stratum of muck and peat beneath.

This most extraordinary condition could not have been found by any means of testing other than sinking deep drill holes, and, even if this had been done previous to the setting of the building, the strength of the clay seam could not have been determined by any test, except the application of a load approximating the entire weight of the structure and contents, which was, of course, impracticable. Only such a weight would have caused the bending of the clay stratum and the consequent yielding of the peat seam.

In the course of the original investigation, test piles 45 feet in length were driven adjacent to the power house, the bearing power of which, computed from the penetration under the hammer blow, was from 12 to 15 tons per pile. It is evident that if a pile foundation had been installed with piles driven to apparently ample depth based on penetration, the condition would not have been discovered in advance, nor the settlement obviated.

The underpinning of the machine foundations was begun July 15th, 1911, and carried on continuously night and day until September 10th, when the plant was put in operation.

Standard pipe or casing 12 inches in diameter was sunk with well rigs to the bed-rock beneath the peat seam around the machine foundation and pipe line immediately behind the power house.

The pipes were pumped out, cleaned, and after inserting steel reinforcing bars, were filled with concrete, forming a system of some 26 steel and concrete piles. Steel I-beams were placed on top of the piles supporting the concrete foundation, wedges being driven as tight as possible between the tops of the beams and concrete of the foundation, and the whole surrounded with concrete. No settlement has been observed since the completion of this underpinning.

The building foundations proper were not strengthened, and no settlement has taken place since the clay stratum was relieved of the weight taken by the piles.

Transmission Line.—The transmission line leading from the power station to the city of Victoria traverses the rough, heavily timbered country along the west coast of the island for a distance of about 40 miles. The first 15 miles of its course is located along the bluff shore line of the Straits of Juan de Fuca, the wires in some places overhanging the sea. No road or trail existed along this section at the time the line was built, and the materials, except poles, which were cut from the adjacent forest, were delivered with small boats along the beach. The remaining 25 miles of the line follows generally the Provincial Government highway, with more or less diversion to avoid acute angles and to shorten the distance.

The current is transmitted at 40,000 volts, 3-phase, 60 cycles.

Cedar poles (with a minimum diameter at the top of 9 inches) are used throughout, 50 feet, 55 feet and 60 feet in height, and spaced from 300 to 400 feet apart. Three steel galvanized cross-arms, each composed of two 1¾-inch by 1¾-inch angles 9 feet long with 1¼-inch angle iron branches are mounted on each pole, all bolts, lag-screws and washers being galvanized. The initial circuit is hung on one side of the pole, leaving space on the other side for the installation of a second and similar circuit at some future time. Brown glazed, two-piece suspension insulators, Locke Type No. 275, are used, one element only being installed for ordinary suspension. At dead end angle points, two elements were used to avoid trouble in adding the second element when the line voltage is raised to 60,000 volts, upon the completion of the second unit. Dead ends were made at all angles where the conductor is drawn toward the pole. Standard line insulators are used on either side of the cross-arm, and the conductor was taken across in a suspended loop.

The conductor is seven strand aluminum cable, No. 00 B. & S. gauge, and is designed to transmit the output of one generator at 40,000 volts, and two generators at 60,000 volts.

Angle Pole on Transmission Line.

A metallic circuit telephone line, No. 9 B.W.G. galvanized iron wire was installed on a short wooden cross-arm below the power wires.

The timber growth along the route of the line is exceptionally heavy, and a very extensive clearing was necessary along and on either side of the line for its protection, all trees being cut that could reach the wires in falling. For many miles a zone from 400 feet to 600 feet in width was cleared through the finest fir belt on the island, and an aggregate of approximately 20,000,000 feet, board measure, of merchantable timber was paid for and cut down in the course of the work, some of which may perhaps be put to profitable use before becoming useless by decay or being destroyed by fire.

Transportation.—One of the most formidable problems of this development was that of transportation. All machinery, cement, pipe, provisions and other supplies, as well as all kinds of labor had to be transported by sea from Victoria, 45 miles down the coast to the mouth of Jordan River. The Straits of Juan de Fuca at this point are exposed to the sweep of the open sea from the west and there was no pier and no natural or artificial protection at the point of landing. Bulky freight was loaded on scows at Victoria and towed by a small tug to Jordan River. The scows, on arrival at the Jordan River landing, were hauled up on runways laid on the flat beach until they were out of reach of the waves, and were then unloaded by derricks.

Making the journey to and from Victoria and beaching the loaded scows in stormy weather was precarious in the extreme, requiring a high degree of patience, courage and skill. Passengers, mail and light freight were landed on the beach in dories.

Although much trouble and some minor accidents occurred, not a single piece of the 6,400 tons of material and equipment handled, nor a single one of the several thousand passengers carried was lost.

From an engineering standpoint the development in its present initially completed state perhaps presents by itself no very unusual features. But when consideration is given to all the elements involved in carving out of a wild, remote and almost impenetrable and trackless wilderness a reliable and highly efficient hydro-electric system, planned for large expansion along accurately predetermined lines, this development presents very unusual interest. Very few hydro-electric developments have presented a greater array of formidable obstacles, many closely concealed, and few have been carried through to successful completion on lines as closely adhering to those originally planned, despite the meagre data on which these original plans were perforce based.

The entire work was under the direction of Mr. Wynn Meredith, of Sanderson & Porter, from the first pioneering to the final completion of the initial installation of the first 4,000-kilowatt unit.

The preliminary reconnoissance and surveys were under the immediate charge of Mr. A. B. Carey.

The final location surveys and all construction work were under the immediate charge of Mr. E. E. Carpenter, to whom we are indebted for the data forming the basis of this article.

ORE PRODUCTION IN MILLIONS.

Metal production at the Consolidated Mining and Smelting Company's smelter at Trail in September reached a value of $715,696, of which 38.2 per cent. was in gold, according to figures recently made public. This is the highest monthly production for the present year and exceeds the average for the previous two months by about $300,000. Ore treated at the smelter totalled 26,099 tons, so that the average value per ton was a trifle over $27. As the greater part of the ore smelted came from the company's Rossland mines which are regarded as low grade properties, this average is considered satisfactory. The Consolidated Company's metal production for the first three months of this fiscal year totals $1,567,867.

Ore production in the Kootenay and Boundary districts for first week in November totalled 51,014 tons, making a total for the year to date of 2,162,902 tons. Smelter receipts for the week were 44,756 tons; for the year, 1,939,934 tons.

THE HYDRO-ELECTRIC PLANT OF THE SHERBROOKE RAILWAY AND POWER COMPANY AT SHERBROOKE, P.Q.

An interesting hydro-electric plant was recently finished for the Sherbrooke Railway and Power Company, at Sherbrooke, Que. The plant was designed by Messrs. Ross and Holgate, of Montreal, and the work was done under their supervision. Mr. C. L. Cate, described the design and construction of the plant very fully in a paper read before the Canadian Society of Civil Engineers, on October 24th. The following abstracts are taken from the paper:—

The city of Sherbrooke is situated 100 miles south-east of Montreal on the main line of both the Canadian Pacific Railway—Montreal to Halifax—and the Grand Trunk Railway—Montreal to Portland. It is also the terminus of the Boston and Maine, and Quebec Central Railways. Excellent water power is provided by the Magog River, which joins the St. Francis within the city limits. The population, at present 17,000, is increasing at the rate of 5 per cent. per annum.

The Sherbrooke Street Railway Company was incorporated by Act of the Legislature of the Province of Quebec in 1895 and began operating in 1896. Power was supplied from a power house in the centre of the city on the south bank of the Magog River, about 1,200 feet from is junction with the St. Francis River. About 100 feet above this power house was a timber dam, built in 1860, and the company had rights to half the flow of the river, the other half being used by several factories on the north bank. The head was 19 feet and the power house capacity 350 K.W.

In the spring of 1910 the Street Railway Company was succeeded by the Sherbrooke Railway and Power Company. Following the inauguration of the old company the population had increased 70 per cent., and the railway had become inadequate, but its expansion was impossible because the old plant was barely able to carry the original car equipment and more power could not be obtained at that site.

The Railway and Power Company proceeded at once to secure the entire power at the old dam, and purchased rights higher up the river so that the water could be raised an additional ten feet. A power 600 feet farther down the river, having a head of 18 feet, was also secured, together with the drop between these two powers. The total head available was about 57 feet, and this has all be utilized in the new plant.

The drainage basin of the Magog River has an area of 815 square miles, of which 283 square miles are in Canada and 532 square miles in the United States. The soil is of comparatively slight depth and the small streams are nearly all rapid. This would tend to make the flow of the stream very irregular and not so valuable for power purposes were it not for the two large storage areas contained in the basin. The greater of these storage areas, Lake Memphremagog, is 30 miles long and has an area of 45 square miles. The difference between extreme high and low water in this lake is five feet, but only a little more than a foot is under actual control at present. In designing a plant, allowance was made for an improvement in this respect, which is likely to be realized shortly. The second storage area is provided in Lake Magog, lying some 8 miles down stream from the outlet of Lake Memphremagog, with an area of 4.8 square miles and a controllable variation of 4 feet.

This lower storage is under the control of the city of Sherbrooke, and the Memphremagog storage is regulated by the Magog Manufacturing Company at Magog. This in no way lessens their value to the Sherbrooke Railway and Power Company's present plant as it is to the general advantage that the flow be kept as constant as possible. Moreover, there is an agreement of long standing by which at least 500 cubic feet per second must be passed when available.

In estimating the rainfall and run-off it was desirable to find a stream having its basin as near as possible to that of the Magog River and on which measurements of flow, rainfall and run-off have been made over a considerable period. That portion of the Connecticut River lying north of Oxford, New Hampshire, was found to serve the purpose very well. The centre of its basin is only about 50 miles south of that of the Magog; the soil is of very much the same nature, and although the country slopes a little less abruptly, this can be allowed for. A Government station has been established at Orford for eight years and measurements of flow, etc., have been taken during that time.

The following table gives the rainfall and run-off for the Connecticut River and the estimated run-off for the Magog, allowing for the fact that the Magog Basin is farther north and the streams somewhat more rapid. Allowance was also made for the fact that in a north-flowing stream the period of heavy flow in the spring is somewhat shorter and more excessive than in a south-flowing stream, because in the latter case the floods from the head waters do not come down until the southern portion has returned to a more or less normal condition. The calculated flow of the Magog in cubic feet per second for each month is also given. In making these calculations a total run-off of 21.5 inches was used instead of 21.66 as given for the Connecticut.

	CONNECTICUT RIVER			MAGOG RIVER

Nov.....	2.17	1.23	5.68	6.	708
Dec.....	2.80	1.28	5.9	5.	590

The flow of the river for a dry year is 580 cubic feet per second, and the flow estimated by the power users on its banks was 550 cubic feet per second, a difference of only about 5 per cent.

With the full 5 foot storage in Lake Memphremagog the flow would be nearly 800 cubic feet per second.

The purposes of the new development are, first, to replace the old plant mentioned above, and secondly, to supply about 2,500 H.P. of electrical energy to power consumers within a radius of 20 miles of Sherbrooke. The greater part of this power will be sold to concerns at least 8 miles from the city and will be transmitted at 20,000 volts. This energy is for the most part already contracted for, and the pole line has been erected as far as the Eustis Copper Mines.

The development consists essentially of:—

(1) A concrete dam with a northern bulkhead section 225 feet long and about 20 feet high, a central overflow section 70 feet long and 44 feet high, a stop-log section 14 feet long,—used during construction to pass water for the old Sreet Railway power house, and which can be used in future as an adjunct to the overflow section, should this become necessary during spring freshets,—and a southern bulkhead section 42 feet long and 12 feet high. The dam contains about 3,400 yards of concrete.

(2) A steel penstock 660 feet long and 9 feet 6 inches in diameter with a standpipe 16 feet in diameter and 56 feet high.

(3) A brick and concrete power house 90 feet x 38 feet with hydraulic and electrical equipment for developing 3,000 H.P.

All concrete used on the work was mixed in the proportion of 1-3-5 except in beams and slabs where 1-2¼-4 was used. Suitable gravel was substituted for sand and broken stone.

Dam.—A 2-inch steel cableway was strung over the site of the dam and used both for excavating and for placing the concrete, bottom-dumping buckets of 1 cubic yard capacity being employed. A boiler and hoist shed was erected on the south bank. The location of the cable-way is shown by a dotted line on Plate III. and it will be seen that it lies just inside the upstream face, and nearly parallel to it, across the northern bulkhead section. At the overflow section it is about 20 feet back of the fact. This arrangement permitted the placing of 85 per cent. of the concrete without building runways.

The concrete mixer, a Ransome No. 28, was located just under the northern tower of the cableway with the gravel bin behind and above it and the cement shed above to the east. Steam for the mixer was obtained from the boilers of a factory on the north shore.

The new dam has been built 50 feet downstream from the crest of the old timber dam and is 10 feet higher. Plate III shows its location relative to the old dam, headrace, etc.

The factories on the north shore had power rights which have not yet expired. They were equipped with electric motors and supplied with power from the city power house and the head gates on that side of the river closed, but it was desired to keep the Street Railway power house in full operation until the power from the new development was available, in order to avoid installing motor generator sets and purchasing power for them.

The course adopted was as follows. The northern bulkhead section was first constructed, the old head gates serving as a coffer-dam. The excavation in this section was not very heavy and, aside from blasting a 3 x 4 cut-off trench, consisted for the most part of earth. A great many pot-holes were found in the rock, which must have been worn in some quite remote period as the river has not been running in that portion of its channel since the country was settled.

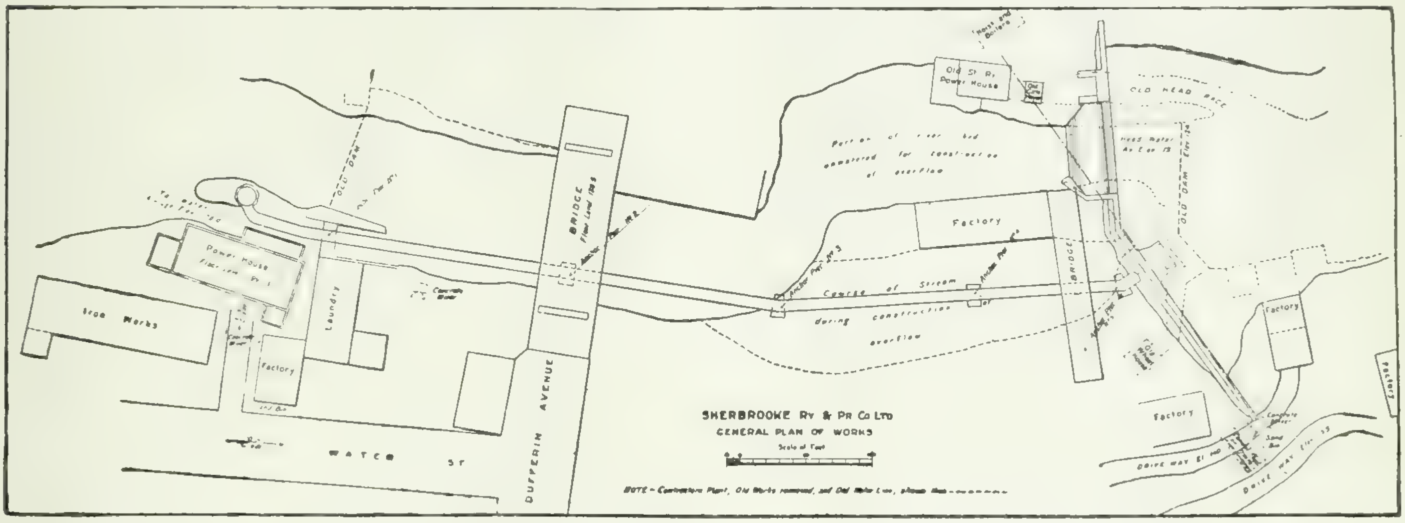
The work was commenced at the north shore and run southward, expansion joints being made every 35 feet. An opening 14 feet wide was left in this section to provide a passage for the flow of the river while the overflow section was being built. The bottom of this opening was about 2 feet below the crest of the old dam. The penstock thimble, which is located at about the middle of the section, was concreted in, and the first sections of the penstock riveted on and blocked up. The racks, which are of steel 3 inches x 5/16-inch spaced 1⅝-inch apart, were also erected, and stop-logs inserted to about 4 feet higher than the bottom of the opening referred to above, it being considered unsafe to leave the penstock entirely open on account of the thrust which would be caused by the swift flow around the 16° angle 10 feet from the dam.

The old north shore head gates were then blown out, permitting about half the flow of the river to go through the 14-foot opening. During the low water, which occurs on Sundays, due to the fact that the factories higher up the river are shut down, the height of the old dam was raised 4 feet by means of flash boards faced with gravel, thus forcing the entire flow through the 14-foot opening and the penstock.

Unfortunately, the old dam leaked badly, and although a diver was procured and everything possible was done to caulk it, it was necessary to construct a coffer-dam immediately below. A coffer-dam was also built about 10 feet below the tail of the new dam.

A flume 3 feet wide and 4 feet deep was built between these two coffer-dams. The nature of the river bottom (huge boulders and gravel) made it impossible to get these tight: Three turbine pumps, an 8-inch on the upstream coffer-dam, and a 6-inch and a 4-inch on the lower coffer-dam, were installed. The excavation for the overflow section was then begun.

Perhaps the most interesting point in the construction of the dam was the manner in which the first 20 feet of concrete was put into this section. The water situation stood thus:—the leakage of the old dam which was being used as upstream coffer-dam amounted to about 2,000 cubic feet per minute. This was caught by a coffer-dam, as above mentioned, and carried across the site of the dam in a flume. Nearly all the leakage of the coffer-dam was held by a natural wall of gravel and shale, and pumped into the flume by an 8-inch turbine pump.



A 4-inch pump, which was moved up from the lower coffer-dam after the river-bed was unwatered, was installed in a sump hole made with sandbags and blue clay just below this natural wall to take the leakage, which amounted to about one-half the capacity of the pump. Below this again, a diaphragm hand pump was placed to take the leakage of the sump hole wall.

The river-bed below the downstream coffer-dam had been pumped out, but the leakage from that side still amounted to about ¾ the capacity of a 6-inch pump. The form for the downstream face was built up to elevation 105, and the suction of the 6-inch pump placed between it and the downstream coffer-dam.

The concrete work was then commenced. A temporary form was built, as shown, just below the sump hole. When the concrete reached the suction of the diaphragm pump, the pump was removed and the leakage of the sump hole wall was forced back through the temporary form by the rising concrete.

When the concrete behind the temporary forms was about 2 feet above the suction of No. 1 pump, No. 3 pump was taken out, the sandbags and clay of the sump hole wall were removed and the temporary form pulled out. This had to be done quickly, as the volume to be filled was so small that the water rose very rapidly.

The concrete was then carried up to about 14 inches below the flume. This permitted the 6-inch pump (No. 2) to be taken out. The flume was cut off at the downstream coffer-dam and the old power house put in operation.

No form for the upstream face had been built up to this time, and although this involved the placing of some 40 yards of concrete in front of the intended face of the dam, it seemed to be the only practicable solution of the problem.

A form of temporary sluice through the dam was then built, the leakage water directed through it and the old flume pulled out. The forms for the upstream face and the remainder of the downstream face were then erected and the overflow section completed. The 70-ft. overflow section is built without an expansion joint, and in order to prevent cracks five 60-lb. steel rails were embedded near the crest. The strength of the concrete mixture was also increased to 1-2½-4¼ in the upper portion.

Four days after the completion of the crest the temporary sluice was closed by a reinforced concrete slab, and filled up through the opening provided. That portion of the Street Railway headrace wall between the dam and the Street Railway head gates was then lowered to the normal head-water level of the Street Railway plant, and the 14-foot opening in the northern bulkhead section was closed by means of stop-logs, checks for these having been provided. Additional stop-logs were also placed in the new head gates to prevent too much water passing through the penstock when the water came up.

In filling the 14-ft. opening it was found impossible to caulk the stop-logs tight enough to put in the concrete, and the following device was used. The back of the stop-logs was 4 inches in front of the face of the dam. A form made of inch boards was built and a 4-inch iron pipe inserted draining into a box 2 feet square at the downstream face. The concrete was put in and the pipe blocked by means of a wooden plug 3 feet long and a cap. The purpose of the plug was to prevent the pipe from freezing and bursting. The box was afterwards taken out and the void filled with concrete.

Two weeks after the completion of the overflow section, stop-logs were placed in the Railway headrace stop-log section and the water was forced over the overflow. The forms, however, were left on until spring. In putting in the stop-logs a space was left underneath them sufficient to pass the water necessary for the Street Railway, the idea in passing the water underneath being that the flow was in that way kept practically constant in spite of fluctuation of level in the river.

The water would probably have been passed over the Street Railway headrace wall for a much longer period had it not been for the large amount of spray caused by the water falling over the high bank. The weather had become bitterly cold early in December, and this spray froze to the walls of the factory building on the rock in the middle of the channel, to a thickness of nearly five feet, threatening to pull the building down. When the flow was passed over the overflow, this spray was eliminated to a large extent, and the ice was removed by means of steam jets and blasting.

Excavation for the dam was commenced on July 7th, 1910, the first concrete was placed August 14th, and the work completed December 10th.

The Penstock.—The penstock is 663 feet long. It is of steel 5-16 inch thick and in 9 feet 6 inches in diameter. The plates are 8 feet long and were riveted up into sections of two at the shops. The penstock is supported by concrete piers spaced approximately 16 feet centre to centre. No expansion joints were used, anchor piers 10 feet x 16 feet on top being placed about 175 feet apart to take care of the expansion and contraction. Three 4 x 5 x ½ inch angles bolted around the lower half of the penstock at each anchor pier to provide for the thrust.

View showing ice formation on walls of factory, (while flow of river was being passed over the old head-race wall).

The piers were built up to one foot lower than the bottom of the finished penstock. Steel rods aggregating 5 square inch cross-section were left sticking in the concrete to secure a good bond. Timbers were placed on the piers and the penstock sections brought to their proper positions, blocked to exact grade, and riveted. 5 inch wrought iron pipe supports were then substituted for the blocking, and the penstock contractor left the job. The concrete contractor built the forms for the upper portion of the piers, constructed a runway on top of the penstock and finished the concrete work.

This method was not adopted in the case of the anchor piers, which were built after the penstock and the ordinary piers were in place, it being specified that the anchor piers were to be of monolithic concrete. In the case of the power house anchor pier, which contains 115 yards of concrete and is 23 feet high, this could not easily be done. Steel rods aggregating 15 square inch cross-section were used in this pier to secure the best possible bond.

The first 8 piers west of the power house are about 15 feet high and average 25 yards each. The power house anchor pier contains, as above stated, 115 yards of concrete. At the time the forms for these piers were completed, the overflow section of the dam was being excavated, and no concrete was being placed at the dam.

The Ransome mixer was brought down to the power house and set up in place of the "Brantford." Steam was supplied from the boiler which had been used to operate the unwatering pumps.

A runway was built across the power house foundations which were at that time nearly complete except for a portion of the floor. The concrete was conveyed from the mixer to the piers in the high wheeled 10 cubic foot buggies which were used for this purpose throughout the work. All piers east of Anchor No. 2 were filled in this way.

Soon after the placing of this concrete the Ransome was required at the dam. The power house walls were also well under way by the time the penstock was in place, and it was therefore impossible to adopt this plan in filling the upper portion of these eastern piers.

A 12-foot Smith mixer was obtained and set up on the river bank between the Dufferin Ave. bridge and the power house and the concrete conveyed on the runway on top of the penstock referred to above. No. 2 anchor pier was also filled from this mixer. It was not practicable to use buggies for this work, as it was considered unsafe to put so much weight on the empty penstock. Barrows had, therefore, to be used.

The concrete for the western penstock piers was mixed by the Ransome at the dam.

The lower portion of several of the piers had to be placed in 5 or 6 feet of water. In such cases a wooden chute 2 feet square, and long enough to reach from the runway to rock bottom, was used. The chute was placed on the bottom and filled a little over half full. It was then raised by means of ropes until the concrete dropped a few feet below the half-way mark and the process repeated. No concrete was allowed to drop through free water.

Anchor piers No. 4 and No. 5 and the most westerly supporting piers could not be finished with the rest, on account of the fact that a portion of the river-flow was being passed through the penstock thimble, until after the concrete in the overflow section had set. These piers were completed on December 20th and this was the last concrete placed out of doors.

In all cases where concrete was placed in cold weather, the rock bottom and forms were steamed for several hours before the concrete was put in. The gravel, water and the mixer itself were also heated. Concrete was placed in this way at a temperature of—10° F. All riveting on the penstock was done by compressed air, pressure being obtained from a small electrically-driven compressor which was set up on the north bank near the power house.

The Power House.—The power house is located on the north bank just below the dam of the lower power purchased by the Company and referred to above. Here, as in the case of the dam, it was necessary to provide power for the factories, etc., and tear out the old flumes before the excavation could be proceeded with.

The earth excavation at the power house amounted to 866 yards and the rock to 1,600 yards. This latter was largely in the tailrace. The total length of the excavation in the tailrace is 130 feet. It was carried down 8 feet below river level. A coffer-dam was erected across the east end and the site unwatered by means of a 6-inch turbine and a 3-inch reciprocating pump. The excavated rock was lifted out by means of a derrick. It was placed in side-dumping hand cars and wheeled to the river bank 250 feet down stream where it was dumped.

The power house consists of a main building or power house proper 90 feet by 38 feet, a transformer house and high tension tower 16 feet by 23 feet, a valve room 50 feet by 10 feet, and an oil house and lavatory 10 feet by 16 feet. The power house floor is 21.25 feet above the tail water.

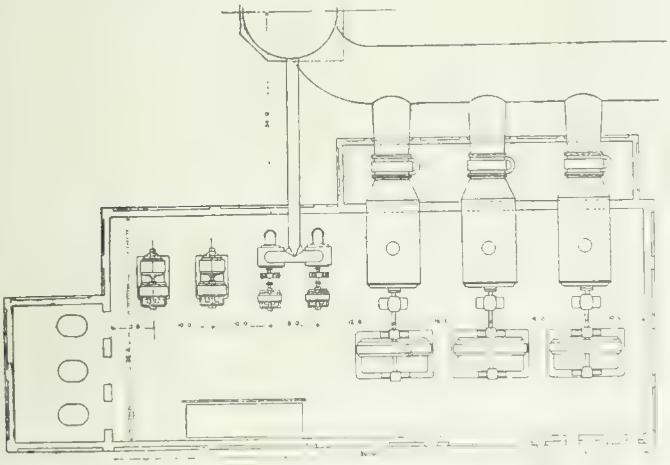
The distributor runs along the south face of the building to the end of the valve room where it is connected to the standpipe.

The valve room is between the distributor and the main building and the transformer house is at the extreme east. The oil house is at the south-west corner.

In the north half of the power house proper the floor is supported on a solid mass of concrete down to the rock. The generators are set on this part of the floor. The south half is suppored by 6 arches with columns running down to the rock. The turbines for the three main units are placed over three of these arches, and the two exciters over the fourth. These four arches have openings through which the draf tubes are let into the tailrace. The motor generator sets are placed over the two other arches.

The valve room floor is a reinforced concrete slab 12 inches thick, supported by four reinforced beams 4 feet by 2 feet, one end of which rests on the columns supporting the distributer and the other on the columns of the main building, with cross beams 3 feet by 18 inches between them.

It was necessary to make this floor very strong, as the 66-inch gate valves for the main units which stand on it weigh 15 tons each.



Plan showing layout of machinery in power house.

The transformer house is supported on 17-inch concrete walls. The floor is a reinforced concrete slab with 3 reinforced beams running along the 16-foot dimension. This floor slopes to the east 1 inch to the foot and a drain pipe is passed through the wall at the south-east corner. This provides for the disposal of any oil that might slop over from the transformers.

The stand pipe foundation is octagonal in section, 18 feet in diameter, and about 25 feet high. It is of solid concrete and contains nearly 200 c. yards. The stand pipe, or surge tank, is of steel, ⅝ inch thick at the bottom and 5-16 inch at the top. It is 16 feet in diameter and 56 feet high.

The roofs of the main building and valve house are built of 2-inch by 3-inch spruce strips covered with 28 gauge galvanized iron. The roof of the main building is supported by three steel trusses with columns running down to the foundations. These columns also carry the crane runs and strengthen the brickwork.

The excavation at the power house was begun on July 1st and the form work was commenced on July 31st. The forms here, as at the dam, were of 2-inch spruce and hemlock planed 3 sides and accurately sized to uniform thickness, band iron was used to hold them together. Clamps were also extensively used. The first concrete was placed on August 5th. The mixer used on this part of the work was a "Brantford Ideal," a machine of the continuous type, and the maximum output under the most favorable conditions was 40 yards per day. This mixer was set up to the north of the site on the west side of the entrance lane.

A glance at the contour lines on the plan of the site will show that the entrance lane slopes down with a 15 per cent. grade to the power house door. One floor of the old factory building is at ground level on the street side, and about 10 feet above the ground at the mixer. The cement was accordingly stored on this floor and emptied into the hopper of the mixer from a platform erected outside one of the windows.

The pocket between the street, which has a 10 per cent. slope, and the factory building was used as a gravel bin. About 30 yards could be stored here. The gravel was wheeled down the hill in 2 cubic foot barrows, that being the capacity of the bucket of the mixer. The concrete was conveyed to the forms by means of runways and 10 cubic foot buggies.

Power House Equipment.—The power house equipment consists of three 1,325 H.P. twin horizontal Crocker turbines with 30-inch runners, direct connected to 750 K.W. (940 K.V.A. at 80% P.F.), 2,300 v., 360 R.P.M., 60 cycle generators, with exciters, motor generator sets, etc., as below described. The supply of water to the wheels is controlled by balanced wicket gates connected by short links, to a rotating ring which is in turn connected to the gate operating shaft by two connecting rods. The whole setting is contained in a steel plate case with a cast-iron end towards the generators and a taper section in the other end connected with the 66-inch motor operated gate valve on the branch from the main penstock. Immediately outside the wheel case, the main shaft is supported by a ring oiling bearing arranged to take up any end thrust from the wheels. Each unit is equipped with a Lombard vertical type Q. 10 governor. Oil pressure is provided by three triplex pumps, one of which is belted to each turbine shaft. The three pumps feed through a common main, and as any two pumps are sufficient to carry the plant, a shut-down due to lack of oil pressure is practically impossible.

Each unit has a 66-inch gate valve with motor drive, one 15 H.P. 125 v. D-C series motor being arranged by means of a line shaft and disengaging gears to operate the three valves. The exciters are 50 K.W. 125 volt interpole machines direct connected to 100 H.P. Jenckes (Crocker) turbines with Woodard governors and hand operated gate valves. Each exciter unit is of sufficient capacity to excite the three main units.

Direct current for the Railway is provided by two motor generator sets consisting of 375 H.P., 2,300 v., squirrel cage rotor, induction motors with a synchronous speed of 720 R.P.M., and 250 K.W., 575 v. interpole generators.

Three 625 K.V.A. oil filled, water cooled, single phase transformers, with both primary and secondary connected delta, are used to step the voltage up from 2,200 v. to 22,000 v. for transmission outside the city. These are located in the transformer house, and are protected by horn and electrolytic lightning arresters and choke coils. All electrical machinery has overload guarantees of 25 per cent. for two hours.

The switchboard consists of:—three generator panels, one transformer panel, one A. C. feeder panel, one motor generator panel—A. C. side, one motor generator panel—D. C. side, one exciter panel, and one D. C. feeder panel. All cables leading from the machinery to the switch-board are laid in ducts embedded in the concrete floor. The generator panels are provided with main oil switches with overload time limit relays, voltmeters, ammeters, etc. The field rheostats are of the iron gird type, and are located in the cable pit behind the switch-board and operated by sprocket chains.

On the motor generator panel, A. C. side, are mounted the operating levers for the starting compensators which are set behind the board. The equalizer switch is mounted on a pedestal between the two motor generator sets. The equalizer connections are on the minus side.

On the exciter panel, besides the regular eguipment, are placed the switch for the gate valve motor, and the lighting switch. This latter is a D.P. D.T. switch permitting the lights to be connected to either the exciter busbars or a 125 v. lightning transformer located in the pit.

The power house is provided with a 10-ton, hand-operated, disturbances by multiple air gap arresters.

The power house is provided with a 10-ton, hand-operated, steel rope, drum hoist type crane of Whiting manufacture. The height of the crane rails above the finished floor is 15 feet 8 inches, and the height to the bottom of roof trusses is 22 feet. The distance from centre to centre of rails in 36½ feet. This crane was used to install the 15-ton gate valves and has given perfect satisfaction.

The contractors for the work were:—The Bishop Construction Company of Montreal for the dam, penstock piers, and power house building; the Jenckes Machine Company of Sherbrooke for the penstock, stand-pipe and hydraulic machinery; and the Canadian General Electric Company for the complete electrical equipment.

Transmission Line.—The 22,000 volts 3-phase transmission line is being built by the Railway and Power Company under the supervision of their own engineer. The line at present under construction runs from the power house in Sherbrooke to the Eustis Mining Company's and the Nichols Chemical Company's works at Capelton.

The poles are of cedar selected under the standard specification of the American Telegraph and Telephone Company both for city and cross country work. The standard length is 35 feet with 40, 45 and 50-foot poles in special locations. They are spaced not less than 50, and not more than 55 to the mile and they extend at least 5 feet into the ground.

The cross arms are 4 inches by 5 inches by 8 feet long with galvanized braces 29 inches by ¼-inch and 1¼-inches. Pins are of oak. The wire used is No. 4-B. and S. solid bare copper with conductivity 97 per cent. of Mathesen's standard.

25,000 volts Locke porcelain insulators will be used entirely for this work.

Costs.—The costs given are for the construction of the dam, penstock and power house, with complete equipment. They do not cover the cost of the site and power rights, as these are of purely local interest.

About one thousand dollars expended on a bridge to one of the factories near the dam and an approximately equal amount allowed the contractor on account of certain hold-ups due to legal proceedings are also omitted.

Dam:—

Excavation:		
Earth, 691 cubic yards at $1	$691.00	
Loose Rock, 100 cubic yards at $1.50	150.00	
Solid Rock, 799 cubic yards at $2...	1,598.00	
Solid Rock below Elevation 102	3,455.00	
		$5,894.00
Concrete, 3,430 cubic yards at $7.75		26,582.50
Stonework		500.00
Stop-logs and fittings		900.00
Total cost of Dam		$33,876.50

Penstock and Standpipe.

Excavation:		
Loose Rock, 362 cubic yards at $1.50	$543.00	
Solid Rock, 388 cubic yards at $4..	1,552.00	
		$2,095.00

CANADA'S IRON TRADE AND COMPETITION.

The reports presented at the annual meeting of the Canada Iron Corporation, Limited, covered the fiscal year ending May 31st last. During the period, as the president, Mr. T. J. Drummond pointed out the adverse conditions prevailing in the United States were severely felt in Canada. Since that date there has been a great revival in the iron trade, but the effect upon the corporation will not appear until next year's reports.

The mines at Torbrooke, N.S., have been re-opened, and shipments of ore from Port Wade will soon be resumed. Then the second new furnace at Midland, Ont., has been blown in, and both furnaces for the first time are now in full blast.

The financial statement shows profits for the year ending May 31st of $375,140. After the payment of interest on bonds and special loan, $265,426, applied in reduction of bond discount and expense, $6,800; merger expense, $9,505; and provision for sinking fund on original bond issue, $46,841, there was added to profit and loss account $46,566. With the $359,807 at credit from the previous year, the total is $406,955.

BRANTFORD CONCRETE PAVEMENTS.

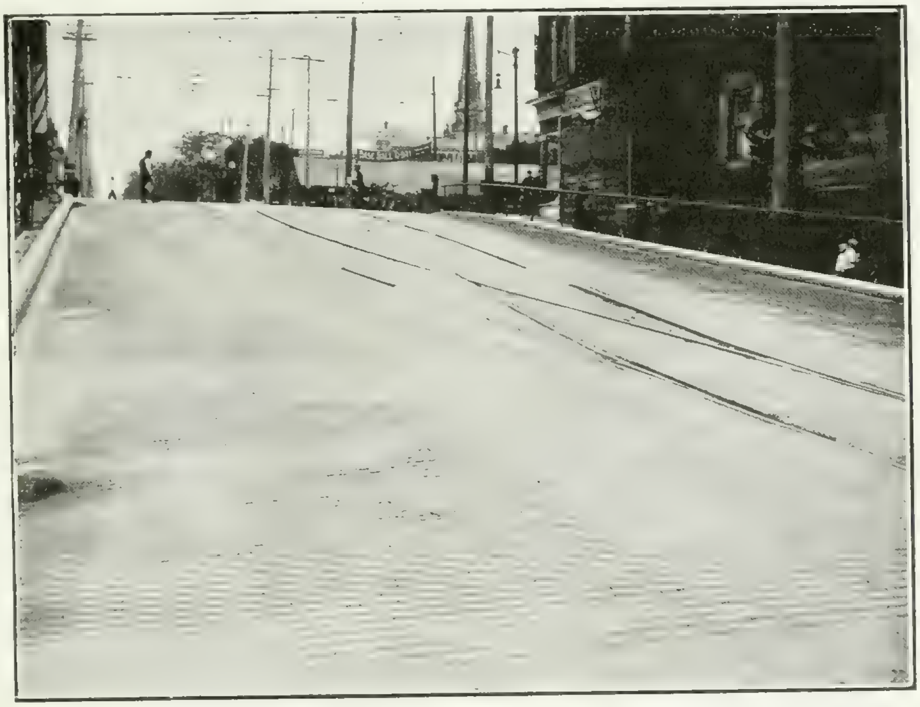
By T. Harry Jones, M.Can.Soc.C.E., City Engineer.

Concrete Walks.—Brantford, I believe, was the first city in Canada to undertake as a municipal work, by day labor, the construction of its concrete sidewalks. Since the first walk was laid, in 1890, by the present overseer of streets, Mr. Hugh Howie, there have been constructed some seventy miles of walks, none of which have required renewal, and only four miles of which were let by contract.

Concrete Crossings.—In connection with the walks, a great many concrete street crossings were put down, and some of these laid twenty years ago are still in good condition. The top surface, which was 1½ inches thick, was composed of 1 part of cement to 1½ of sand.

Private Concrete Driveways.—Some private driveways were also constructed, one put down in 1900 and subjected to the heavy traffic in connection with a wholesale warehouse, being in as good condition as when laid. This was 12 feet in width, 6 inches in thickness, the top coat of 1½ inches being mixed 1 to 1 and being corrugated every 6 inches.

Concrete Bridge Floors. — In 1908 the roadway of the concrete bridge, 85 feet long and 16 feet wide across the canal on Alfred Street, was laid with concrete. It was 6 inches in thickness, the top coat of 1½ inches being composed of 1 part of cement to 1½ of sand, with surface corrugations every 6 inches. This is in good condition and is wearing well. The floor of a steel bridge laid this year by the Hamilton Bridge Works Co., leading to the waterworks, was constructed by the city in concrete. It is 75 feet in length and 16 feet wide and is a one-course pavement, formed of a 1 to 5 mix with bank gravel, the thickness at the centre being 6½ inches, and 4½ inches at the sides. An expansion joint is left in the centre filled with a ¼ inch steel plate, with anchor bolts every three feet.



Concrete Pavements on Market Street, Brantford, Ont.

(Showing surface corrugations on an eight per cent. grade)

As regards permanent pavements, on our public streets, however, previous to 1908, the words of an old proverb were applicable, which spoke of a certain roadway, with a steep down-grade to an undesirable locality, as being paved with "good intentions."

Concrete Foundations, Curbs and Gutters.—In 1908 contracts were let on certain streets for bitulithic and westrumite pavements, including the concrete foundation, but since that year the top surface only of this class of pavement has been let by contract, the city doing the grading, concrete foundation and curb and gutter, resulting in the saving of about 25 cents per square yard on the 50,000 yards laid.

The thickness of the foundation is 5 inches on residential streets and 6 inches on business streets, the mix being 1 to 7 of pit gravel obtained in the city, it being very suitable for concrete work.

Instead of using broken stone spread over the surface of the concrete, as had been the custom of the paving companies, rammers with steel projections were used which gave the uneven surface necessary to bind the concrete with the top surface.

The cost has averaged about 12 cents per square yard for the grading, and 38 cents for the concrete foundations and 45 cents per lineal foot for the curb and gutter. The average depth of the curb face has been 6 inches, and the width of the gutter 15 inches.

Concrete Street Pavements.—Speaking generally, the sub-soil of the city is sand and gravel, and very suitable for this class of pavement.

After the sub-grade is shaped it is rolled with a 15-ton steam road-roller. On this the concrete is placed and thoroughly tamped, great care being taken to protect it from debris or from being walked upon by passers-by or the workmen on the pavement. The crown is shaped by a wooden template cut to the curve of the street, which on narrow pavements is worked from curb to curb, and on wider ones from the curb to a scantling 6 inches wide on top, 5 on bottom and 6 inches deep, placed in the centre of the street parallel with the curb.

This strip is afterwards removed, the sides broken in and filled with concrete, and the whole surface finished with a wooden float worked from a plank bridge extending from curb to curb. A drier of dry cement and sand mixed 1 to 2 is spread over the surface in finishing.

All the cement used was subjected in the city engineer's department to the standard tests prescribed by the Canadian Society of Civil Engineers, a Fairbanks testing machine being used for the purpose.

The crown of these pavements is now determined by the following formula by Ernest McCullough, published in *The Canadian Engineer* May 26th, 1909:

$$C = \frac{W\ (100-4p)}{6000}$$

C = crown in feet

W = distance between curbs in feet.

p = per cent. of longitudinal grade.

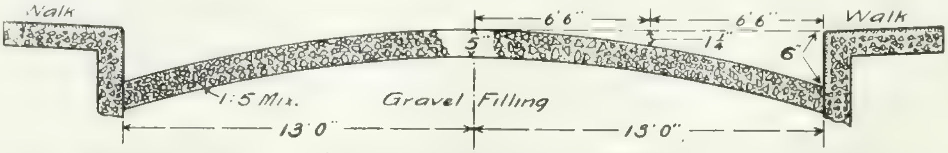
This works out a crown of 5 inches with a 26-foot pavement on a 1 per cent. grade.

The flat crown results in a more even distribution of the traffic over the surface of the street.

Lorne Crescent Pavement.—This is a one-course pavement laid in 1910, its length being 394 feet and its width 24 feet.

The depth of the concrete is 6 inches, being mixed in the proportion of 1 part of cement to 6 of pit gravel, the crown being 5 inches.

Transverse expansion joints, at right angles to the curbs were left about every 30 feet, some of the joints being filled with pitch, others with wood strips, and a few with neat cement. No contraction joints were left. No transverse cracks have appeared in the pavement, but most of the blocks have developed longitudinal cracks at the centre. The pavement, however, was laid late in the year and was caught by the frost. The cost was 80 cents per square yard, which includes in every case 5 per cent. for engineering.



Plan Showing Section of Concrete Pavement on Chestnut Avenue, Brantford.

Chestnut Avenue Pavement.—The length of this pavement is 535 feet and its width 26 feet. It is a one-course pavement and was laid in 1911. The grade of the street runs from less than 1 per cent. at the upper end to 5 per cent. at the lower end. The crown varies according to the grade, being about 5 inches at the upper end.

The depth of the pavement is 5 inches, the concrete being composed of 1 part of cement to 5 parts of crushed gravel and sand. Transverse joints, at right angles to, and extending from curb to curb were left every 33 feet. The joints were made by pine strips ¼ of an inch wide at the top and 1 inch at the bottom, extending the full depth of the concrete. A contraction joint was left in the centre of the pavement parallel with the curb for a distance of 110 feet of the upper part of the street. This was also filled with wooden strips similar to those used in the expansion joints. Although subjected to the heavy teaming from the gravel pit at the foot of this street, and also to the test of the last severe winter, no cracks have developed, even in the part of the pavement where no contraction joint was left.

Laying Concrete Pavements at Brantford.

It is our intention in future work to try a protecting plate at the contraction joints, as used in the Wayne County roads to prevent the wearing at this point. The cost of the pavement was 85 cents per square yard.

Market Street Pavement.—This pavement, laid this year, extends from Colborne Street to the new reinforced concrete Victoria bridge, its length being about 200 feet and its width from curb to curb 40 feet, the grade running from 8 per cent. at Colborne Street to 5 per cent. at the bridge. A single track of the street railway curves into double tracks at Colborne Street, the part between the tracks being paved with bricks.

This is a two-course pavement 6 inches in depth, the bottom course of 4½ inches being formed of 1 part of cement to 4 of gravel and broken stone. The top course of 1½ inches is composed of 1 part of cement to 1½ of clean sharp sand, and was put on immediately after the first course had been put in place.

Corrugations ½ inch in depth were left every 4 inches at right angles to the street and afford a sure foothold for horses.

This pavement, being at the intersection of the two main business streets of the city, is subjected to the heaviest traffic. No expansion of contraction joints were left. A slight transverse crack has appeared on the lower part of the pavement above the bridge.

General Remarks.—The sand, gravel and broken stone used in our concrete work is from our own pits, drawn in Brantford dump wagons. The road bed is rolled with a Brantford Waterous road roller, and the concrete mixed in a Brantford Goold, Shapley and Muir mixer. The cement is made by the Ontario Portland Cement Company of this city at their works at Blue Lake in this county, and Brantford labor alone in employed in the construction of these pavements.

It may be stated generally that the citizens are well pleased with the concrete pavements which have been laid.

Concrete Pavement on Lorne Crescent, Brantford, Showing Expansion Joints.

The cost is only about half that of the other kinds of permanent pavements, the cost of maintenance is less, they are low-crowned, less slippery and easily cleaned.

The white surface on residential streets, I consider attractive. If preferred, the surface can be colored.

It may be of interest to state that in addition to the cost of street intersections and exemptions on corner lots of half the total frontage (not exceeding 50 feet) that the city bears 40 per cent. of the cost of all pavements, and that the number of payments is extended over 10 or 15 years, according to the estimated life of the work.

ROAD MAINTENANCE.

The maintenance and repair of roads after they are constructed is most important. There is little use in constructing new highways if they are not to be kept in the best of repair. The methods and experience of the New York State Commission of Highways is of interest in this connection, for they have at the present time upwards of 3,151 miles of State and county highways to be maintained. Many of these highways were constructed in the early years of road-building in the State, and of a material and character of construction that at that time was supposed to be the best. Just when it was thought that the problem of good roads had been solved, along came the automobile and its destructive accompaniment, as far as the highway surface is concerned.

The Commission state that after the use of various experimental materials they find that the more recently constructed macadam highways, with a bituminous binder, and those which have been resurfaced with similar top dressings, can be maintained under the patrol system at a minimum expense.

The cost of maintenance throughout the State appears to us abnormally large, the average cost per mile appropriated for 1912 being $926. About 1,000 miles of the 3,151 miles under maintenance, however, are being given a top course of fine stone or gravel and oil treatment.

The extension of the improvement of the highway system of the State has called into existence a class of traffic which was never contemplated in the original scheme. This is the use of traction engines in hauling heavily loaded cars and in the use of motor trucks. As a result, the roads, where regular freight lines of motor trucks have sprung into existence between large towns, and which were not built for such traffic, are being destroyed. The Commission suggest that the time has arrived when legislation should determine the economical limit of load per inch of tire.

◆

TEARING UP STREET PAVING.

With the introduction of street paving and community waterworks and other evidences of civilization into our cities and towns, the vexing question of alleged inefficiency in the matter of various civic departments overlapping, with a net cash loss to the ratepayers, became more and more evident; chief among these charges was the opening of recently paved streets for the laying of gas and water mains. In a Western city this old and time-worn question has cropped up, and one or two of the civic officials have striven to smooth out the ruffled tempers of the already overburdened taxpayers, and some of the points in their argument are worthy of consideration. They contend that the cost of installation of water and gas services into vacant lots prior to the erection of buildings is in excess of the paving repairs, and that the services and fittings lying in the ground are liable to deterioration and damage for their long burial, and they further contend that the holders of vacant property do not have the slightest idea as to what position they desire the services placed in.

In a city in Eastern Canada some months ago an appropriation was made to cover the cost of a new water main, and the plans were prepared, showing the line that the work was to follow, and a goodly portion of the pipe went up a residential street that was to be repaved, owing to the unsightly and unsafe condition of the asphalt owing to numerous openings and patchings. The pavement was stripped and a beautiful new coating of asphalt replaced, but the same was down only a few days when a deep trench was cut to allow of the placing of the water main. This was some weeks ago, but at the present time the trench is covered with the torn blocks, which are supposed to act as weights and compress the earth back into a sufficient degree of hardness to permit repairs. In the case of this water main, and in many other cases where this unnecessary and unbusinesslike work has been done, there have been considerable expanse of lawn offered as a desirable location for the pipes, but these apparently do not meet with favor, probably owing to there being no newly-laid pavement to rip up.

◆

TECHNICAL SCHOOLS.

As the remarks made by Mr. Walter Dixon, in his presidential address to the West of Scotland Iron and Steel Institute (to which reference was made in a recent issue of the London Times,) regarding the questionable benefits conferred upon manual workers by schools and technical colleges are based upon enquiries made in industrial districts throughout the British Isles among those who control many thousands of workpeople, they must be accepted as evidence that in the opinion of a proportion of employers most of the book-work beyond the rudiments of reading, writing, and arithmetic is superfluous for manual laborers; and they must be taken as indicating that the additional educational facilities scarcely afford real aid even to foremen, charge men, and other leaders in the workshops. In general terms this criticism may be said to accord with certain of the facts, but as an argument against those additional educational facilities it fails to convince, for the reason, recognized by Mr. Dixon, that the educational schemes in the Old Country, as applied to the industrial classes, have purposes beyond those appertaining to wage-earning, and in the main the United Kingdom is the healthier, the cleaner, and the happier for them. Consequently the "bread alone" principle cannot be accepted as a basis for criticism of a system of education for industrial localities. There is need, however, that great watchfulness should be exercised in regard to reading, writing, and arithmetic, for with the advance of mechanical appliances, instruments of precision, and manufacturing processes, the demand for proficiency in these subjects is daily increasing. If it can be shown that the teaching of additional subjects is detrimental to the acquisition of those cardinal elements of school work, the system stands condemned. The average employer, knowing humanity, however, will probably express the opinion that blame is due less to the teaching than to the learning.

EDITORIAL COMMENT.

The current issue of the "Electrical Review," of London, England, has come to hand. With this issue our contemporary celebrates its fortieth anniversary. We extend our heartiest congratulations to the journal, with best wishes for its continued success.

LETTERS TO THE EDITOR.

LIGHT COMPRESSION MEMBERS.

Sir,—I have read with much interest the valuable discussion by the Western Society of Engineers on "Light Compression Members" printed in *The Canadian Engineer*. The variety of opinions is not only interesting, but valuable to all those who read your paper. Permit me to add, however, an opinion which seems to me to have been overlooked in the discussion.

One of the assumptions on which column design is based, whether long or short, is that, assuming a centrally applied load, the stress is uniformly distributed over the sectional area of the member, and that, assuming an eccentrally applied load, the stress is of a uniformly varying distribution. We know from experiment that the distribution of stress over the sectional area of a single piece of metal in simple tension is not uniformly distributed, but is greater at the edges of the section. Therefore, it would not be at all unreasonable to assume that the distribution of stress in compression would be higher at the edges than at the centre.

Looking at the matter in this way, one can easily see why the "built-up" member should fail by wrinkling of the plates between the rivets at a unit stress which we suppose to be much less than it really is.

The spacing of rivets in "built-up" compression members is based on the assumption that the plate between the rivets acts like a short column, and is limited in length, i.e., the distance between rivets along the axis of the column—by the ratio of $1/r$, which, coupled with the assumption of a uniform distribution of stress, goes to make up the present theory of rivet spacing in columns. A theory based on an assumption of higher stress at the edge of the section would lead to a shorter allowable rivet pitch per given thickness of cover-plate, and hence a much safer design; a state of affairs which we will probably reach sometime in the light of further experimental evidence.

Yours very truly,

I. F. MORRISON,

University of Alberta, Edmonton South, Nov. 23, 1912.

Sir,—I have read with interest Mr. I. F. Morrison's comment on the discussion of "Light Compression Members" by the Western Society of Engineers, which was recently published in *The Canadian Engineer*.

The effect of possible inequality of stress distribution over the cross section, apart from that due to eccentricity, imperfect materials or poor workmanship, is no doubt considerable, as Mr. Morrison points out.

His assumption that the stress at the edges of a compression member will be greater than at the centre, however, does not appear to be well founded. The fact that this is true for a simple piece subjected to tension in a testing machine is no indication that the same thing will be true of an ordinary column. The method of fastening a tension piece in a testing machine is largely responsible for the inequality of stress distribution, the grips applying the load to the edges of the piece instead of uniformly over the cross-section.

Our assumption of uniform stress per unit of area is based on the application of the load to all parts of the cross-section in equal measure. If the load is applied at a point on the cross-section, manifestly all fibres cannot be stressed equally. The elasticity of the material of itself, apart from the effect of slag threads, seams and longitudinal cleavage planes, precludes the transference of the load so as to give a uniform stress. The fibres close to the point of application of the load will be heavily stressed while those remote from it will bear a lighter stress. It would thus appear that with a central load on a column, considered as applied practically at a point, the outer edges would be stressed less than the portion of the cross-section directly under, or near, the point. For loads applied at other points than the centre of gravity of the column, the stress would vary in a similar manner, being most intense at the point of application of the load and least intense at the point most remote from it.

Yours very truly,
C. R. YOUNG,
Consulting Structural Engineer.

318 Continental Life Building, Toronto, Nov. 30, 1912.

THE FREEZING TEST OF STONE.

The Mines Branch, Department of Mines of Canada, is making a complete reconnaissance of Canadian stone resources, and Vol. 1, covering the southern part of the Province of Ontario, has just been issued by the Department. Professor W. A. Parks prepared this report. Most of the stones were tested, and in this work the following observations were made:—

The freezing test which was applied to the samples of stone is described in the report as follows:—

A 2-in. cube was carefully prepared and dried in the air-bath at a temperature of 110° C. for 24 hours, after which it was allowed to cool in a desiccator and was then weighed. The cube was then saturated with water under reduced pressure for 36 hours, after which it was exposed to 40 alternate freezings and thawings. The specimen was again dried in the air-bath, and crushed in precisely the same manner as the unfrozen samples of the same stone.

The freezing test in this form is not considered by Mr. Parks to be entirely satisfactory, as the soaking in water is likely to make the stone contain very much more water than it would contain when ordinarily exposed to the weather, and, therefore, the conditions of the freezing test are not closely parallel to natural conditions. On the other hand, to make a freezing test on stone when containing only a normal amount of water was regarded as impracticable because its moisture would be so low as to require a very great number of freezings and thawings to give appreciable results. In default of something better the above described method was adopted. It is thought to give results of only very approximate value; i.e., the figures obtained from the freezing test should not be interpreted directly as a gauge of the weather-resisting or freezing-resisting power of the stone.

The following remarks on the general results of this freezing test are given:—

In the case of granites, gneisses, crystalline limestones, and marbles, there was a uniform loss of strength, but in the case of the limestones and sandstones, while the majority of the specimens lost in strength, there were some which increased to an appreciable degree. As there could not well be an instrumental error to account for the high result of the frozen specimens, new cubes were made of the stones in question and the crushing strength of the unfrozen sample again determined with the greatest nicety possible. In every instance a result nearly identical with the original test was obtained, so that we are forced to conclude that, in some cases, stone actually increases in strength by being subjected to the operations described.

It is not to be inferred that the freezing and thawing has produced this result; the explanation more likely lies in the heating and drying. An increase in strength after freezing has been recorded by various authors, but it has generally been attributed to lack of care in preparing the material. Buckley evidently considered such results anomalous, for he explains them as due to imperfect cubes or to the manner of operating the testing machines. Merrill gives a table in which five stones out of fifteen increase in strength, but he does not offer any explanation of the apparent anomaly.

Mr. Parks explains the phenomenon as being due to the formation of fine fragments in the interior of the stone as a result of solution and the disintegration due to freezing and thawing, followed by a subsequent recementation of the fine particles. He has actually observed this cementation as follows:—

At the time the old lithographic quarries near Marmora, Ont., were in operation, the fine dust obtained in working the stone was barreled with the intention of using it as a polishing material. Several of these barrels were left in the mill, and by the simple process of becoming damp and drying out, protected from both sun and rain, the contents have been converted into a solid mass rivaling the stone itself in hardness.

Two specimens of almost identical appearance, one of which gained in strength under freezing test, while the other lost materially, were reduced to powder, wetted, raised to a temperature of 100°, again wetted and allowed to soak for a few hours. On being raised to a temperature of 110° C., the pellet obtained from the stone which gained in strength showed a very much greater coherence than that from the other.

Elsewhere in the report, in giving the detailed description of the Marmora quarries, the author says:—

It is an interesting fact that the shavings from the planers if wetted and allowed to stand, set to a cement of considerable strength.

The relation of this observed cementing of the stone powder to the result of the freezing tests is summarized by the author as follows, with an observation also on the effect upon strength of wetting the stone:—

If it should be definitely established that the operations of drying, freezing and thawing, and again drying, tend to raise the crushing strength of certain stones, it follows that the recorded loss of strength does not really represent the loss due to freezing, but that loss less an increase due to the resetting of the disrupted particles.

In this connection may be mentioned the fact that most of the sedimentary stones lose appreciably in strength on being wetted; this loss of strength is due to the softening of the cementing material, which holds the grains together. On again drying, the stone assumes its original hardness and coherence.

RAILROADS AND VANCOUVER.

It was stated in the city this week that the Grand Trunk Pacific was in the market for canneries, something along the same line as the principals of the Canadian Northern.

The Canadian Pacific Railway has big works on its hands. It will erect a large office building in Victoria for its own accommodation. In Vancouver, it is stated that the Canadian Pacific Railway is calling in on its wharfage. Mr. R. V. Winch has about 100 feet of Canadian Pacific Railway wharf frontage, while the Union Steamship Company has another section immediately east of that. Notice has been given Mr. Winch that the Canadian Pacific Railway will want the piece he occupies, and it is thought it is only a matter of time before the Canadian Pacific Railway will want all it holds. The railway company now occupies wharves equal to the frontage of nine city blocks, and this does not take into account a jetty several hundred feet long.

AN AERIAL TROLLEY CAR.

By L. McCully Edholm.

Although suspended cars have been used successfully in Germany for a number of years, many new features have been devised in the aerial trolley system at Burbank, California.

The car is torpedo shaped with a framework of steel covered with aluminum. It is fifty feet long, seats fifty-six persons, and has carried capacity load with ease.

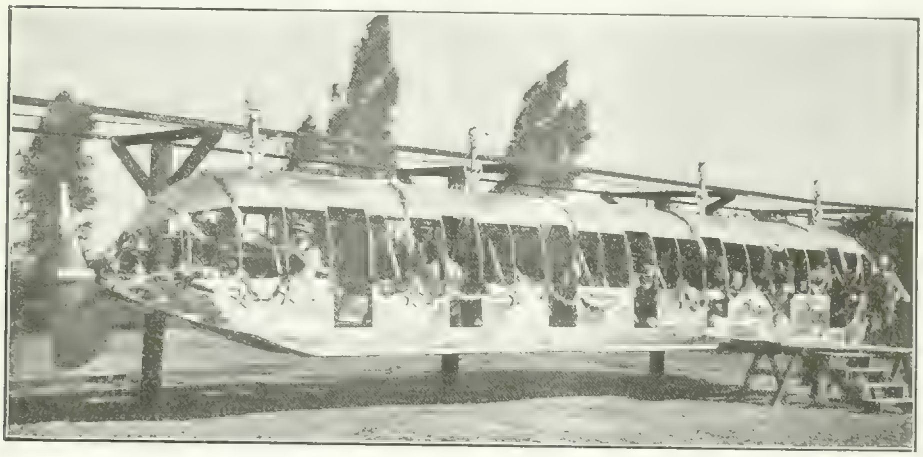

Fig. 1.—View of Aerial Trolley Car Ready for Operation, at Burbank, Cal.

The chief difference between this and other aerial cars is that it is driven by a six-foot propeller of unusual construction, having two fan-shaped blades of sheet metal, on ribs of steel tubing.

To serve in case of accident to the propeller and engine on the back of the car, a second propeller and motor will be placed on the front. This can also be used to double the power, if desired, or to hold back on down grades by reversing its motion.

This unique propeller is far more efficient than the kind used on aeroplanes because of its large surface. It is operated by a four-cylinder 25-h.p. gas engine, such as is used in automobiles. The propeller is capable of one thousand revolutions per minute and on a long stretch of track it is claimed that the car can easily make one hundred miles an hour.

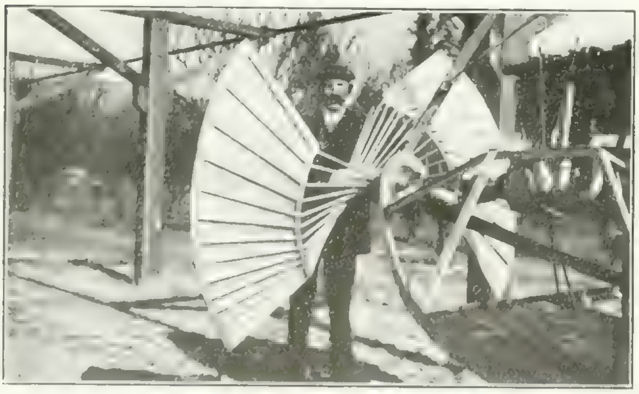

Fig. 2. View of Fan-shaped Propeller.

The track in use at present is six hundred feet long and it built on the estate of the inventor, Mr. J. W. Fawkes. The tracks are supported on posts, some of steel and some of wood, with cross beams to correspond. This is in [illegible] both kinds.

The rails used are steel T-beams three and a half inches broad, and three-eighths of an inch thick, and scientifically trussed to prevent sagging. The car is held securely to the rail by means of four sets of grooved wheels firmly clamped both above and below the rail, so that there is no danger of it jumping the track.

Another interesting point is the tilting planes to lighten the car by air pressure when it is in motion, and also an apparatus to lower and raise the cars at the stations.

It is claimed that this trolley line is much more economical to install, costing approximately $2,000 per mile and $1,500 for each car. It has many advantages over the old systems, as it can be built over hills and across rough country as easily as on the level stretches, the height of the track being regulated by the length of the pole. In fact, part of the Burbank system crosses a ravine by means of poles of various heights.

Mr. Fawkes is now considering the building of a double-track line between Los Angeles and one of the suburban towns. For commercial purposes his idea is to have a five-track system, the lower tracks for local transportation, while the upper one is for a "flyer."

This system will do away with all street congestion and collisions, so common under the present conditions, as all grade crossings are to be eliminated and the cars will be suspended at a height of twelve feet or more above the street.

Mr. Fawkes has proven his success as an inventor by a number of electrical devices which have won him a comfortable fortune.

◆

A NEW STEEL SCREW STEAMER.

A successful launch took place from the Neptune Works of Swan, Hunter & Wigham Richardson, Limited, on Thursday, the 7th ult. The vessel launched is a fine steel screw steamer which is being constructed to the order of the Cork Steam Ship Co., Limited, of Cork, and is the 24th steamer built and engined for that company at the Neptune Works.

The vessel is 285 ft. in length by 38 ft. beam, and is designed to carry over 2,700 tons deadweight on 19½ ft. mean draft. She is being built to attain the highest class in the classification of Lloyds registry.

The propelling machinery is also being constructed at the Neptune Works, and consists of a set of triple expansion engines supplied with steam by two boilers, and will propel the vessel at a speed of 11 knots per hour.

The steamer will be amply provided with the latest and most improved loading and discharging gear, including seven steam cranes, steam winch, etc., for her service in the line carried by the Cork Steam Ship Company between Liverpool, Manchester and Dutch and Belgium Ports.

As the vessel left the ways she was named the "Vanellus," the christening ceremony being gracefully performed by Miss M. E. Pease, of Middleton Lodge, Middleton Tyas, niece of Mr. Joseph Pike, the chairman of the Cork Steam Ship Company, Limited.

Amongst those present were Miss Pease and Miss Dorothy Pease, Mrs. Finch, Mrs. F. Christie, Mr. J. D. Christie, Mr G. F. Tweedy, Mr. G. B. Richardson, Mr. Rendall, Captain Hore, of Liverpool, marine superintendent to the Cork S.S Co., and Mr. J. A. Flockhart, of Liverpool, their superintendent engineer.

THE CONSTRUCTION OF A WEST AFRICAN RAILWAY.

The placing of the construction of the Accra-Akwapim Railway, in West Africa, in the hands of a contractor was an entirely new departure on the part of the Colonial Government. Previously all the railway construction in both the Gold Coast Colony and the adjacent colonies had been carried out by their respective governments departmentally, and a departure from that practice was looked upon as an experiment. Mr. William Martin Murphy, of Dublin, Ireland, was the successful tenderer, the official notification of which fact was sent him under date November 3rd, 1908.

Exactly one month afterwards the first party of engineers and foremen overseers sailed from Liverpool, arriving at Accra on the 20th December.

The construction of the work was described in a paper by Mr. G. M. Harriss, read before the Institution of Civil Engineers, of Ireland, recently. The following details are abstracted from that paper:

Amongst the West African natives are men gifted with intelligence of a high order, and in Accra are to be found craftsmen of nearly every kind, who, with a little direction, are capable of turning out excellent work.

Sections Showing Types of Construction.

The ordinary laborers take to pick and shovel work well. They will not, however, under any circumstances, use wheelbarrows; everything is carried on their heads.

Female labor is available, and was largely used for carrying of all kinds, including the water for the concrete, the concrete when mixed, and the earth from the cuttings and for the banks. The women are very satisfactory, and are, as a rule, more industrious than the men. They will not, however, go far from the towns or villages.

The earth is carried in baskets holding about 55 lbs. when heaped up; the usual average working quantity would be between 30 and 40 lbs. Native-made baskets can be procured readily; they are made from a strong vegetable fibre plaited, but they are neither so strong nor so well liked by the natives themselves as specially imported English baskets. These are of a wicker-work construction, and last much longer than the native baskets. Both the water and the mixed concrete are carried in ordinary galvanized iron buckets.

One or two head-women go with each gang of twenty or more. They usually give a hand in lifting the loaded baskets on to the carriers' heads. The boys do the pick and shovel work, fill the baskets, make the concrete, and fill the buckets. If ahead of their work they will often help the carriers to get their loads up. A head boy or a second head boy will not, however, give any such assistance in the same way as a head woman will. If there is no other assistance at hand the carriers help one another, and will stoop down with their loads on their heads to assist each other.

Most of the stone-breaking for the concrete was done by female labor. The women are particularly fond of this work, though not very expert at it. They are, however, more satisfactory at the stone-breaking than boys, as they like the work and are more industrious.

The women like working, and are keen on making money; but they are independent of this class of labor. There is no poverty in the country; neither men, women nor children need go hungry. The ordinary rates for women is 25 cents per day, and for boys from 30 cents to 36 cents. Skilled native labor is dear—good carpenters get up to $1.20, blacksmiths and fitters more than this. The ordinary laborers come from various tribes, speaking different languages. Nearly all speak and understand a kind of English, only to be learned on the coast.

The ordinary hours of work were from 6 a.m. to 11 a.m., and from 1 p.m. to 5.30 p.m. Saturday was a half-holiday, work ceasing at 1 o'clock. This made a 54 hours' week.

The first sod of the railway was cut on January 7th, 1909. The railway runs due north for a distance of thirty-nine miles into the Akwapim district, where the cocoa plantations commence.

The site of the railway terminus is situated a mile and a half from the coast, in the hollow of a valley about fifteen feet above sea-level. A small branch line was constructed from an existing line, about two miles in length, already laid down for conveying stone for the harbor works. This put the new terminus in rail communication with the beach and breakwater, which was a first necessity, the available space at the beach being so limited that nothing could be stacked there, and all had to be cleared every day.

The country a few miles from the coast is densely covered with thick bush, which must have presented tremendous difficulties to the railway surveyor.

In the flying surveys through the bush some surveyors gain a great deal of information, and save a good deal of clearing, by the use of aneroid barometers, with assistants at either side, each assistant being furnished with a speaking trumpet, through which the barometer readings are transmitted to the surveyor—he taking the bearings judging direction from the sound.

For the finished survey a rough clearing was made along the centre-line with pegs at every chain (66 feet), and, where possible, the apex of each curve was marked by a concrete block, about 18 inches square and 2 feet 6 inches long, standing 18 inches above the ground.

These blocks were numbered, and so permanently marked the most important points for after reference.

The original survey, as well as the plans and specifications were prepared by the joint consulting engineers to the government, Messrs. R. Elliott-Cooper and Frederick Shelford, of London.

It may here be mentioned that the actual construction of the line was governed by the fact that the standard weight for transport is limited to what the natives can carry on their heads, on account of the tsetse fly which abounds inland and makes the use of beasts of burden impossible. The transport of tip wagons and the horses to work them, and the transport of locomotives before the rails are laid is therefore impossible. This causes an important departure from the ordinary practice, almost universal everywhere in railway work, of so setting out the line that the material taken from the cuttings bears a reasonable proportion to that required for the banks. The banks are in this case formed by digging trenches or "borrow" pits at both sides. These are kept well clear of the finished toes. The earth from the borrow pits goes to make the banks. The material from the cuttings is rarely or never used in banks, and goes to spoil.

Under these conditions the making of a bank costs per cubic yard about half that for a cutting, and of course in the cuttings there is always the danger of meeting rock, in which case the cost will be multiplied by five or six. These facts influence the building of the railway and show their mark on the finished work. The engineer in search of a cheap line avoids all the cuttings he can, and does not care how far they under-proportion the banks. The following are the figures for the first twenty miles section of this railway:—

	Miles.	Cu. Yds.
"Formation" (level with the ground)..	4.67	—
Cutting	3.11	28,070
Bank	12.25	222,098

It will be seen that the cuttings only provide some 12 per cent. of the material required for the banks, even if it were used in them. As a matter of fact none of it was.

It is provided that the banks have a camber below the ballast. It is very important that this camber be made in the first instance and maintained while the banks are standing for settlement; it prevents the water from collecting in pools or small lakes, which eventually break out in a stream down the slopes, and these streams in the heavy tropical rains become small rivers, cutting gullets, often five or six feet deep, in a short time. During the rains these gullets give great trouble. They have to be carefully watched and stopped, especially when the banks are new and soft, and uncovered by vegetation. This camber will not remain after ballasting, as practically all the first ballast will go down to formation level, and below it, when the traffic starts.

After twelve months' maintenance, with a reasonable train service over the first twenty miles section, the writer found from his own experience that three times the original ballast provided for in the contract was added. In some cases, such as in cuttings, and where the formation was hard, there would not be so much, but in some of the banks, where the earth was taken from the borrow pits, it was of a soft and spongy nature, and up to four times the original quantity of ballast was required in places.

The buildings at the Accra terminus are of a substantial concrete construction, and include a fine main station building and a building containing the manager's office and the general offices. There are also a large engine shed and repair shops, fitted with a 25 h.p. oil engine and a good supply of machine tools, and a well-equipped smithy, in addition to separate buildings for a general goods store and railway supply store. All these are of concrete. There is also a carriage shed, 250 feet long, of steel and iron, with two lines of rails. In addition, there are large bungalows for the first-class officers, smaller bungalows for the European foremen, and quarters for the native staff—all being included in the contract.

The rain-water from the roofs of the station buildings is led by stone-ware pipes to the principal underground tank [illegible] in the [illegible]

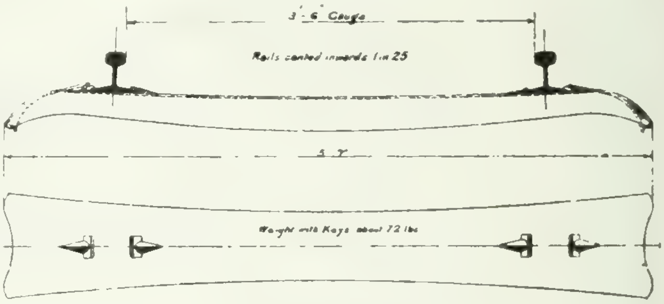
All the bungalows are provided with large cast-iron water tanks.

This is necessary, as the fresh water supply for the Europeans and the better class natives is that gathered from the roofs of their bungalows and houses, when it rains, and stored in tanks.

By the middle of February, 1909, laborers in gangs of from 100 to 200 boys were working at the clearing and earthworks, and gradually these were increased until there were gangs on different sections over the entire line. A white man, who was responsible to the engineers, looked after one and sometimes two of these gangs. As to the engineers, the line was divided into two sections, each under a district engineer responsible to the chief engineer.

At the same time that the clearing and earthworks were going on large gangs were working at the Accra terminus and the station buildings.

In the year 1909 the wet season was not a very severe one, and good progress was made at both the clearing and earthworks. When culverts were necessary, gaps or openings were left in the banks, and, as far as possible, the culverts were afterwards put in, in advance of the track-laying, using the line as much as possible to bring up the material for the culverts. But where the culverts were large, the openings for them were provided with temporary crossings to prevent holding up the linking-in gang.



Steel Sleeper.

The linking-in was started from Accra as soon as the banks had settled, but at an easy rate to allow of the culverts being completed, and avoid over-running them.

It was not until early in December, 1909, that much pressure was put on this work; but throughout that month the linking-in was done at the rate of a mile a day. This appears to be about the amount for efficient and economical progress, when rail head gets much beyond ten miles from the stacked material, except under very favorable circumstances, such as where there is flat and open country and a reasonable supply of water available for the locomotives, when, perhaps, another quarter mile might be added.

When the line is practically all carried on banks with stiff gradients and many curves, such as exist on the Accra-Akwapin line, a mile forward is a very good day's work. The trouble is not so much to get the actual linging-in done as to get the material to the plate-layers.

The gauge is 3 ft. 6 in., the weight of rails is 45 lbs. per yard, and the steel sleepers weigh 72 lbs. The latter are rather too heavy for one boy to carry, though there are numbers of them who do carry them with ease. The rails are 30 feet long, and eleven sleepers go to the length—distance centre to centre of sleepers 2 feet 9⅝ inches for 30 feet rail, and 2 feet 2 inches at the joints. Ballast is not easily got along the line, and is only to be found in a few places where pits have been made, and these average up to 5 miles apart. On that account the track was first laid direct on the formation level. Light engines were used to bring up the rails and sleepers, and these were brought along the track as fast as it was linked-in by the plate-laying gang. In this way the distance the rails had to be carried by the boys was kept as short as possible. The sleepers were usually thrown off, to be picked up and carried well ahead, when they were carefully laid on the formation square to the centre line and the correct distance apart. From ten to fourteen boys take a rail from the loaded truck, hold it above their heads, and carry it direct to its place, laying it on the sleepers to the satisfaction of the plate-layers. The plate-layers with their bars cant the rail, getting it under the clips of the sleepers. Considerable practice is necessary to do this quickly, and only well-trained gangs are of any use at the work. The bank at each side of the material train is reserved for the rail-carriers—the sleeper-carriers must go on the outside, either at the bottom of the bank or as best they can. As soon as a pair of rails are in place and fished up by the plate-layers the material train moves forward. The keying-up is usually left over for a more convenient time.

When three or four miles of linking-in had been done that work was stopped, and the ballast, which had been previously got ready at the ballast-pits, where separate gangs were engaged, was loaded and distributed over the length, and the first lift party, usually gangs of 100 to 200 boys, put in the ballast with a first lift from 8 inches to 10 inches. The remainder of the ballast was put in later in three or more lifts of from 3 inches to 4 inches each. A permanent gang was then left to maintain the line—the number varying from 4 to 6 to the mile; one native plate-layer with second man being in charge of a three-mile section, with a European plate-layer in charge of six or more gangs.

From the terminus the main line runs level for half a mile, then through a soft rock cutting, with a gradient of 1 in 100 falling 11 feet, to where the harbor line crosses and from that point the formation is level up to 2 miles 2 chains over open country and flats of grass land. These flats in places are marshy, the average height of the bank over them is about 3 feet. The flats continue for another mile at a slightly higher level, when the line is merely formation or level with the surface of the ground.

Standard Section of Ballast.

From 3 miles 0 chains the level rises in easy gradients up to 7 miles 63 chains. The country then gets more uneven, and is more or less covered with bush, but is still fairly open. At this point, which is the site of the first intermediate station—Dome—the level is about 79 feet above the flats. The line then rises with a gradient of 1 in 80 up to 8 miles 42 chains, then with an easy gradient down for 30 chains. It again rises to 9 miles 48 chains, when there is a depression, which the line crosses on a bank 7 feet high, with a gradient of 1 in 80—the line at this point being 55 feet above Dome station, or a total of 134 feet above the flats. It was between this point, 9 miles 48 chains, and the harbor line crossing that the most trouble with floods was afterwards experienced. From that point there is a stiff pull —1 in 80—up to 11 miles 14 chains to the top of a range of hills which runs parallel to the coast line. These hills must be crossed in getting from the coast to the interior. At the top there is a deep cutting mostly rock. This cutting is at a level of 216 feet above Accra terminus, and is the highest point on the line.

There is a long gradient of 1 in 80 down again to Ensaki Swamp at 13 miles 0 chains, then a rise to 15 miles, the site of the second station—Amasama—which is at the top of a second lower range of hills. After passing 11 miles the cooler sea breezes are lost, and the heat is much more intense—Ensaki being particularly hot and close in the middle of the day.

From Amasama the country is of a more undulating nature—thick and close bush continues in N'Sawam, and immediately after N'Sawam the forest is reached.

At the end of December the rails were laid for the first 27 miles, and in May practically the whole of this length was ballasted and packed, and was in good running order as far as N'Sawam.

The wet season of 1910, which started on June 6th, was, however, the most severe remembered, no less than 18 inches of rain fell between June 6th and 18th. This quantity very frequently represents the total rain-fall at Accra for a year. The whole of the Achimotah valley, through which the line runs, was one great running river. The banks were carried away at 5 miles, 5 miles 27 chains, and 5 miles 47 chains, and in many other places they were totally submerged.

In the wet season of the year 1908 this valley was quite dry. In 1909 very little water ran through it. These great floods were quite unexpected, and did tremendous damage to the line, making it quite impossible to get any material up, so that all progress was stopped for a time. As soon as it was possible every effort was made to repair the damage. Where the banks were carried away timber sleepers were built up in the form of cribs to support the lines, and openings were left. The cribs were so arranged that the concrete foundations, abutments, and wing walls for permanent openings could be put in without interruption to the traffic. Rail girders, consisting each of nine rails packed together, were used to carry the line over the cribs.

Early in August, 1910, through communication was again established, and on the 27th of August the line was publicly declared open for traffic as far as N'Sawam.

The original contract provided for a line to Mangoosi, and the earthworks were completed and the rails laid to that point, but the ballasting was stopped at a point one and a quarter miles short of Mangoosi, as it was then practically decided that an extension would be made to the town of Komfrodua, about fourteen miles further on: under those altered conditions the original site for the Mangoosi station was not suitable, and a new site on the opposite side of the hill upon which the town stands was selected.

Pending a final decision as to the extension, this line remains unfinished for the last mile and a quarter from the point where the route to the proposed new station site would commence.

In the meantime, the end of the line, as far as regular passenger and goods traffic is concerned, is at present at Pakro, which is thirty-four miles from Accra, or six miles beyond N'Sawam, and the contractor, under agreement with the Gold Coast government, is working the line over this length.

It is difficult, if not practically impossible, in the first survey, in tropical countries to reasonably estimate the effect of heavy rain-falls, especially where, as at Accra, the natives can give no reliable information of any kind on the point, and no previous records are to be found, and observation of old watercourses and flood-water marks are also impossible, owing to the luxuriance of the tropical growth which conceals all evidence of previous floods.

In consequence of these June floods it was found necessary to increase the openings under the line either by additional openings or by substituting culverts of greater width for those originally constructed.

In addition to the flood-water openings, the banks were raised over several miles of the line, principally through the Achimotah Valley, but also near twenty-three miles and over the Pom-Pom swamp, which is above N'Sawam.

The whole of the above work, including the addition of the bridges and the raising of the banks, was done without interruption of the daily traffic.

It will be readily understood that the successful carrying out of such an undertaking as the building of a railway in West Africa largely depended upon the perfect organization at home, as the mail boats take seventeen days in the passage from England, and the cargo boats five weeks. One large ship, containing a supply of coal for the engines, was wrecked on the coast, and the work would have been much hampered if there had not been a reserve supply on hand. Another cargo ship, containing some materials for the railway, was lost with all hands and never heard of. Everything that may be conceivably wanted has to be sent with a margin to spare, and well in advance of requirements. Great precision and a highly-organized system directed from home is an absolute necessity to prevent the work from coming periodically to a standstill. Everything required for railway track and station building construction, and for housing provisioning, and furnishing for the staff had to be anticipated and sent out in advance, so as to be available when required.

Bungalows for tne officers and quarters for the men and a fully-equipped hospital building were sent out in sections ready for erection.

The rolling stock for the construction consisted of two 6-wheeled locomotives (duplicates) with outside cylinders, 12-inch diameter, 18-inch stroke, 6 wheels coupled 3 feet 1 inch diameter, gauge 3 feet 6 inches, fire-box of best selected copper with brass tubes, 84 in number, 2-inch diameter, with 2 special hot water injectors, side tanks, holding 470 gallons of water; wheel base 8 feet 6 inches; weight, loaded, about 24 tons.

One with 9-inch cylinders, 15-inch stroke, 4 wheels coupled, 30½ inches diameter, gauge 3 feet 6 inches, fireboxes of copper with brass tubes, 50 in number, 2 inches diameter, 2 sirlus type injectors, saddle tank, holding 300 gallons of water, wheel base 5 feet, weight, loaded, 12½ tons.

The government provided the permanent rolling stock. This includes licomotives, weight 50 tons, covered-in carriages, with both first- and second-class, fitted with lavatories, also brake-vans for the guards. For the passenger traffic a very comfortable corridor train can be made up with this rolling stock.

For the goods traffic both open and closed trucks are provided. These are of steel construction. Hand-brakes are fitted on each carriage and truck. These can be operated from one of the platforms at the end of the carriages, and in the case of the trucks, both open and closed, either the hand-brakes or the couplings can be attended to when standing on a small platform which is hung on buckets at a height of about 12 inches above the rail.

Only European engine drivers and guards are allowed with the regular goods and passenger traffic. Mostly native drivers attended to the ballast and material trains while the line was being constructed and before it was opened to public traffic.

A five-chain curve was put in at the junction of the main line and the harbor branch, so arranged as to complete a third side of a triangle. This provides a means for turning an engine or the whole train if desired.

All the engines take water at Accra, which is taken from the well. When water is scarce the well is kept continually pumped to get the best supply, and the large underground tank is kept filled. Both are drawn from when the demand is heavy; when not heavy the underground tank is filled up.

During the dry season of 1911 there was always enough fresh water from this source for the railway requirements, and frequently there was some to spare for the harbor works where they were at times very badly off, and were obliged to get fresh water brought from N'Sawam by rail.

There is a good supply of fresh water at N'Sawam, which is on the Densu River, and also a fair supply at Ensake Swamp, 13 miles. At these two places there are tanks fitted for watering the engines.

The joint consulting engineers for the line are Messrs. R. Elliott Cooper and Frederick Shelford, of London. The resident engineer is Mr. Douglas Grey. Mr. Arthur J. Salter represents Mr. Muphy on the Gold Coast, and Mr. T. E. Etlinger is his chief engineer.

◆

REPORT ON HAMILTON SEWAGE DISPOSAL WORKS.

A report was made recently on the sedimentation tank. which is located in the north-east corner of the city of Hamilton, by Dr. John Amyot, Provincial Bacteriologist. Dr. Amyot visited the plant in the early part of November, and on November 23rd made his report to Dr. McCullough, Secretary of the Provincial Board of Health. The following is the text of the report:—

As a sedimentation basin, which was intended for a septic tank, it is too small for the purpose. It was reported to me that the sludge had never been removed from it, thus its capacity is much reduced over what was first intended. There are no means provided for handling the sludge if they desired to handle it.

According to the engineer, the hydraulic head provided for the carrying of the effluent from this tank to the sprinkler filters is not sufficient to reach the lower end of these beds. The beds themselves are built of very irregular material as to size and quality, much of which is crumbled by weathering, and possibly by the action of the sewage sprinkled upon them. The greater bulk of it is in good condition if it were properly sorted and could be made use of.

There is no foundation to the beds; the slag has been thrown right on the clay, thus making one of the most serious mistakes in its construction. Such beds, in order to work efficiently, must have a straight-away, unimpeded flow of drainage.

On account of the diminished sedimentation and the presence of iron waste in the sewage, heavy deposit of hydrate of iron and clay has taken place over practically the whole surface of the beds, thus sludging them completely and preventing them being put to the use they ought to be. If the sedimentation tank had been efficient, most of the iron would have precipitated in the tanks and not gone on to the beds and destroyed them.

I also found a lack of appreciation of the principles of sewage disposal in reference to these beds, and would in consequence advise as strongly as possible that a sanitary engineer accustomed to this particular type of sewage plant be employed by the city of Hamilton before any alterations are made.

Much of the plant can be used over again but special advice should be received in reference to this.

DEVELOPMENT OF POWER IN EASTERN CANADA

The latest factor in the power field is the Eastern Canada Power Company, it being through the instrumentality of that company, apparently, that Mr. McGibbon is putting forward the following scheme. The formation of this company was announced fully a year ago, it being stated that a wonderful scheme of power development was contemplated by the concern. Sir Max Aitken was said to be the organizer of the company, and it was stated that the amount of power to be produced was very large. The story attracted considerable interest at the time, especially as there then seemed a probability of keen rivalry between the Montreal Light, Heat and Power Company and the Canadian Light and Power Company, each of which companies possessed hydraulic developments thirty miles from the city in the vicinity of Cedar Rapids. About the same time, also, Mr. D. Lorne McGibbon had succeeded in getting control of the Cedar Rapids power. Just where the Eastern Canada Power Company was going to get its enormous power from was somewhat of a mystery.

In the course of the following year Mr. McGibbon's plans for developing the Cedar Rapids Power were matured, and it began to be rumored that he was selling out control to certain other interests. The story was at first denied, but its truth was ascertained later. It was admitted that some of the principal interests in the Montreal Light, Heat and Power Company and the Shawinigan Water and Power Company were the purchasers. This meant that the Montreal, Light, Heat and Power Company was now in control of practically all the sources of hydraulic power located within commercial distance of Montreal.

A recent dispatch from Ottawa is to the effect that Mr. McGibbon now appears in a larger power scheme. It is proposed to build an enormous dam in the vicinity of Coteau, Cedar, Split Rock and Cascade Rapids for the purpose of developing an hydraulic power with an estimated capacity of 1,000,000 h.p. The dam will connect up a number of islands in the vicinity mentioned, and will have a total length of, perhaps, fourteen miles. The rapids will thus be dammed up to a level with Lake St. Francis, thus obliterating them and flooding a portion of the Soulanges Canal. The proposal is from the Eastern Canada Power Company, and behind it are Mr. McGibbon, and with him Sir Max Aitken. The proposal has already been brought before the government at Ottawa, and, so it is believed, has made progress with the powers there.

The other big power scheme is the Long Sault Development Company, which is backed by the Aluminum Company of America. This, also, is before the government at Ottawa, but whether it is in any way opposed to the Eastern Canada Power scheme or not is impossible to say at this moment. It may be remembered that the Long Sault scheme was brought up at Ottawa during the regime of the Liberal Government and met much opposition from the Conservatives, and, on the recommendation of the conservation commission, was not adopted. For some time past the Long Sault Scheme has been showing new life once more. It has been written much about and discussed, and there is no doubt that another attempt will be made at Ottawa.

The Long Sault scheme is not quite so ambitious in some respects as the Eastern Canada Power Company. Instead of a development of 1,000,000 horse-power, one of but 600,000 to 800,000 horse-power is claimed, and the engineering problem, it is stated, would not be anything so vast or complicated. On the other hand, however, the consent of both the United States government and the Canadian government would have to be obtained. These governments both refused consent in the past. Subsequently, the governments have been changed in both countries, and the new governments may feel more kindly disposed to the proposals.

Canadians must feel that the leasing of these powers in the St. Lawrence River is one of the most serious matters dealt with by parliament in many decades. They are the last big, commercially available powers in Canada, and their absorption by private interests can only mean that the advantages of ownership will be absorbed by the owners, whether these be the private interests or the country at large. The Hon. Clifford Sifton, as head of the conservation Commission, made the statement that "leases of these powers for limited periods" was the proper method, and in his suggestion there is much to commend.

INTERNATIONAL PAPER COMPANY AND CANADA

The report of the International Paper Company for the year ended December 31st, 1912, will likely show the largest net earnings in any year since 1905, the directors anticipating that it will total about $6,000,000. Discussing the decline in this company's stock, it was suggested in New York last week that if a reduction were made in the paper tariff, the plants of the company in the United States might be transferred to Canada with very little expense.

The company is producing at the rate of about 1,750 tons of paper a day. The production varies from 1,746 to 1,777 tons. Of this, 80 per cent. is news print. The remainder of the output consists of tag paper, box paper and supplement paper. It is selling its product at $2.25 per 100 pounds and finds the market favorable, so that its entire output is sold. Beginning next year, International Paper will begin supplying news print on several new contracts, of which the New York Sun is the largest. The Sun contract calls for 40 tons of news print per day. The Sun is now receiving its paper from the Great Northern Paper Company and is paying less than it will have to pay on the new contract at the first of the year.

International Paper is spending considerable money in improving its property and has expended a large amount of money for this purpose during the last three years, and now has a profit and loss surplus of approximately $9,000,000. One of International Paper's greatest assets is its ownership of timber lands in Maine and Canada. The policy of the company is not to use its own wood where it can buy in the open market at a reasonable price. Directors of International Paper believe that the timber lands should be held as a final reserve, and should not be used until the price for wood pulp timber in the open market advances too much.

The International Paper Company was incorporated in 1898 in New York for the manufacture and sale of pulp and paper, and was a consolidation of nineteen paper producing companies. Among the concerns it controls are the Miramichi Lumber Company, incorporated in 1905 in Maine. It has rights to cut timber on about 415,000 acres of Crown land limits in New Brunswick. It also controls the St. Maurice Lumber Company, incorporated in 1891 in New York. This company owns cutting up and wood preparing mills at Batiscan, Three Rivers and Pentecost, Quebec, with water powers and rights to cut timber on more than 2,000,000 acres of Crown land limits in Quebec.

The International has authorized common stock of $20,000,000; 6 per cent. cumulative stock, $25,000,000; and a bonded debt of $16,473,000, exclusive of $1,189,000 bonds of controlled companies.

TELEPHONE TRAIN DESPATCHING. †

By Mr. Hatton. *

How many are there in speaking of the transportation of the country's products, or in travelling by train, ever give a thought to the principle of train operation, or the problem of train reverse movements; in other words, the indispensable train order system?

It is not necessary for me to enter into that subject to-night, suffice it to say, that the system dates back to 1851, when Superintendent Minot, of what is now part of the Erie Railroad, issued the first train order, after vainly trying to run trains without it. The system has undergone many changes since that time, having been the subject of discussion by some of the brightest minds in the country at conventions and elsewhere, until the present almost perfect system has been evolved. From the first, the telegraph, which at that time was also only in its infancy, was the instrument of transmission of the train order. A few years later the telephone was invented, and, while it was the subject of much wonder and admiration, and likely to revolutionize methods of communication, it was not looked upon seriously by railroad men as a competitor to the telegraph, in so far as train operation was concerned. People evidently had no idea at that time of the vistas of usefulness that would later be opened up to it along that and other lines. The question of using it in place of the telegraph did, however, come in for discussion at different times, and it was actually put into use in a small way for the handling of trains as early as 1883. A few interurban electric lines adopted it some years afterwards, but it was not until 1907 that the steam railways experimented with it to any extent. Probably the first real experiment was made by the New York Central Railway in October of that year, when a telephone despatching circuit was installed between Albany and Fonda, New York, a distance of forty-six miles, followed by the Chicago, Burlington and Quincy Railway in December of the same year, with forty-five mile circuit on one of their lines running into Chicago. The trial in each case was so successful that other lines became interested, and these circuits were inspected by a great many of their representatives during the following year. In every case I believe a favorable impression was made, and those who came prepared to scoff put in a report recommending it, which resulted in the installation of a number of additional circuits on other lines, including the Canadian Pacific. The extension has since been so rapid that to-day of 87,700 miles of road on seventeen American railways over 38,000 miles are operated by telephone. I have not the figures for Canadian lines, except the Canadian Pacific, but this line has kept pace with its American neighbors by installing telephone despatching circuits on 4,858 miles of track, or on over 40 per cent. of its entire mileage, the circuit extending, with but two short breaks, from the Atlantic to the Pacific and on several of the most important branches. Before attempting to explain the reason for this remarkable growth I will give a brief description of the equipment.

The best results being obtainable from a metallic circuit, a pair of heavy copper wires is used for the line, these being transposed at frequent intervals to eliminate interference through induction from other wires as much as possible. By this means and with the use of good telephone apparatus, etc., a very clear transmission has been secured. It is not affected by wet and foggy weather, as is the telegraph, nor is the circuit as liable to interruption from other causes. The average circuit is from 110 to 140 miles long, but that is not the limit by any means, for in one or two instances of 250-mile circuits the result is almost as satisfactory as with the shorter ones. The number of offices on each varies, of course, but often runs as high as 25 and 30. These can be cut in singly or collectively. The apparatus consists of a signalling device and the necessary telephone equipment, the latter being very similar to the ordinary telephone, the despatcher using breast transmitter and head-band receiver, which gives him the free use of both hands, and is always accessible to call from any station. The station telephone is much the same, except that in some cases an arm with adjustable transmitter and receiver attached are used. There are several varieties of signalling devices, but all work practically on the same principle, the equipment in each case consisting of what is called a master selector in the despatcher's office, whose action is semi-automatic, and a sub-selector with bell attached, in each of the stations. In the case of one of these devices the master selector consists of a number of units, that is, a separate arrangement for every office, the whole enclosed in a small cabinet, and placed in a convenient position on the despatcher's table. Each of these has a different combination, and to each is attached a small key. By giving this key a quarter turn it continues mechanically until the contact point is reached, when the circuit is completed and the bell is rung in the office having a similar combination. From five to six of these operations can be made in a minute, which, of course, means that many offices can be called in that space of time. This constitutes one of the many advantages the telephone possesses, for, in addition to the ease with which the calling is done, the responses are usually more prompt than with the telegraph, as many of our agents and operators having duties, such as checking baggage, etc., taking them from the immediate vicinity of the office, may not hear the telegraph at once, while their attention is immediately arrested by the telephone bell. It is also possible to work with one office at the same time that other offices are being called without the transmission being in any way interfered with. These features are appreciated by all despatchers, meaning a great saving of time, labor, and sometimes temper. A great amount of time is also saved in the repetition of orders, for with the telegraph a distinct operation is necessary in transmitting each character, while with the telephone the order may be repeated as fast as the operator can talk. By reason of the quickness of transmission the despatcher is also able to keep his train sheet up in better shape than ever before and with much less actual effort. There is not the same necessity for condensing or restricting information in connection with train movement, etc., which might be of great value if given, but with the telegraph is omitted, because of the time it takes to spell out letter by letter every word of such information. The despatcher is also able to speak direct with conductors and engineers if necessary, thereby securing more accurate knowledge of details than was ever possible with the telegraph. In order that train crews may get in touch with despatcher in case of a delay between stations a portable set is furnished every passenger and freight train, making telephone connection possible at any point on the line by simply hooking a jointed pole with flexible cord, which is also carried on the train, on to the proper wires and connecting it with the portable set.

By talking with agents and operators, the trick despatcher saves many messages a day that would otherwise be necessary regarding cars, etc. In fact, in a hundred ways the telephone not only saves time, but labor.

It is not easy to figure out just what these several advantages mean in dollars and cents, but it is variously

---

* Superintendent Car Service, Canadian Pacific Railway, Winnipeg.

† Paper read before Western Canada Railway Club, [illegible] 14th, 1912.

estimated that the capacity of the despatcher is increased from 25 to 50 per cent. It is also only reasonable to conclude that on account of the contact between despatcher, operator and trainmen being of a more personal character results in a closer co-operation and a more efficient service.

Now, with regard to the most important point of all, the question of safety, the telephone again has the advantage. In the first place, the despatcher in sending an order by telegraph does so without a written copy for reference, and has no record until the first operator repeats it. With the telephone he copies the order at the same time he is sending it to the different offices, so that the repetition can be checked directly against his own copy and an error on the part of the operator immediately detected. Numbers of trains and engines names of stations and other essential words in order are spelled out by letter as well as pronounced, so that a mistake is almost impossible.

In conclusion, I venture to say that, while great advancement has been made in the selective and telephone apparatus and installations in the short space of five years, still further improvement is in store, and the time is not far distant when the telephone will have almost entirely supplanted the telegraph for the despatching of trains. It is also coming into use quite extensively for the transmission of local messages and in this respect also will run the telegraph a hard race.

In speaking thus, I am not oblivious of the telegraph's wonderful achievements in the past, nor blind to its future possibilities, but I am convinced that for the purposes I have described the telephone has triumphed over it.

VANCOUVER'S PROPOSED HARBOR COMMISSON

As noted previously in *The Canadian Engineer*, at the next session of the federal parliament a bill is to be introduced by Mr. H. H. Stevens, M.P., to provide for placing the port of Vancouver under a commission of three, two members to be appointed by the government for terms of five years, and the other by the city council, for a term of three years. The commission, if the bill passes, will be empowered to improve, operate, maintain and govern Vancouver harbor.

The proposed port limits will include Burrard Inlet with the North Arm and Port Moody, False Creek and English Bay; in fact, all tidal waters to a line drawn from Port Atkinson to Point Grey. The commission is to be the pilotage authority.

The commission may acquire, expropriate, lease and dispose of lands deemed necessary for development, improvement, maintenance and protection of the harbor; may acquire movable property, plant, vessels, machinery, etc. It can acquire property for wet or dry docks, warehouses, elevators and railways in connection with the harbor, and all tidal lands within the harbor limits shall be under its jurisdiction. Further, the commission may construct and operate tracks and harbor lines and may make agreements with railroads, affording all companies whose lines reach the harbor equal facilities for traffic. Laws governing the harbor not contrary to laws existing or the jurisdiction of the corporation may be enacted, fairways, special anchorages, etc., regulated, and the navigation of the harbor will be generally managed by the commission. The harbor master will be appointed by the commission.

Rates will be levied at discretion upon all goods landed or shipped in the harbor, moved by rail on the harbor tracks, excepting military supplies. Powers will be given the commission to borrow such moneys as are necessary to carry on its work, and debentures may be issued to cover such loans. The governor-in-council may advance funds necessary to complete the harbor works. Salvage disputes will be heard by the commission and all wreckage or flotsam dealt with.

Upon certain conditions the commission may seize vessels or goods, the detention being effected upon order of any judge or magistrate having power of two justices of the peace. Judicial powers will be given the commissioners to cover infringements of the Canada Shipping Act within the harbor limits. The government may waive duties on all merchandise required for the port commission work.

HARBOR IMPROVEMENTS AT NEW WESTMINSTER

New Westminster is seemingly entering the most active building period of its career. A statement which is creating great interest in New Westminster, Port Mann and every part of the Fraser River is that Messrs. Mackenzie and Mann have rejected the agreement between Vancouver and the Canadian Northern Railway.

It is stated that the clauses which Messrs. Mackenzie will not accept are those binding them to make Vancouver their home port, to enter the city by a tunnel and to purchase additional property in the city for their hotel site. If this report ultimately proves to be correct, it will only be in accordance with the steady conviction of a great many that the Canadian Northern Railway would never go to a vast expenditure to make Burrard Inlet their shipping point when they already owned a port capable of magnificent development at Port Mann.

New Westminster's harbor developments may also have had some influence on the Canadian Northern Railway's decision. These are taking concrete shape, and the expenditure of the $500,000 worth of bonds that have been sold for this work will begin very shortly. Mr. Powell, the engineer in charge is calling for tenders for 3,000 linear feet of cedar pile quay wall and 1,000,000 yards of back filling with rock rivetted slope. This is for the widening of Front Street to 192 feet, and the construction of a straight municipal quay of over a mile in length.

COSTS ON THE PANAMA CANAL.

The annual report of Col. Gorthals, chief engineer of the Panama Canal, gives some interesting unit costs on the work during the past year.

Excavation in the prism by steam shovels was cheapest in the Central division, averaging $0.5101; in the Atlantic division a lower cost is shown than during the previous year —$0.5952 against $0.6010—while in the Pacific division it is higher—$0.7527 against $0.6960. There was a total of 1,443,570 cu. yd. of masonry laid in the locks and spillway during the year. The unit costs for the masonry were: Gatun Locks, $7.7552; Gatum spillway, $7.0988; Pedro Miguel Locks, $6.4640; Miraflores Locks, $4.7675. The labor costs for the year per cubic yard of plain concrete at the various locks and spillways show lowest at Miraflores, $0.8394; next, Gatun Locks, $1.3840; Pedro Miguel Locks, $1.4733; and Gatun spillway, $1.5425.

The cost of concrete piling at Gatun was $0.0679 less during the year than in 1911, while the cost in place was $0.7088 less. The total amount driven was 83,670 lin. ft., at a cost of $1.5719 per lin. ft.; in addition, 51,450 lin. ft. of wooden piles were driven, at a cost of $0.6516 per lin. ft. On this basis had wooden piling only been used for the south approach pier a saving of $77,000 would have resulted.

APPLICATION OF CONCRETE TO UNDERGROUND WORK.

Concrete has been used for many years in building underground dams, bulkheads, etc., some notable examples of which can be seen at the Chapin mine at Iron Mountain, Mich. Mr. H. T. Mercer, in a paper presented to the Houghton meeting of the Lake Superior Mining Institute, describes some of the applications of concrete in mining work. He states that the principal uses of concrete in mines are in connection with shaft support. Good examples of concrete shaft collars can be seen at many of the mines, and although the details vary somewhat, a description of one or two will perhaps suffice to illustrate this form of construction.

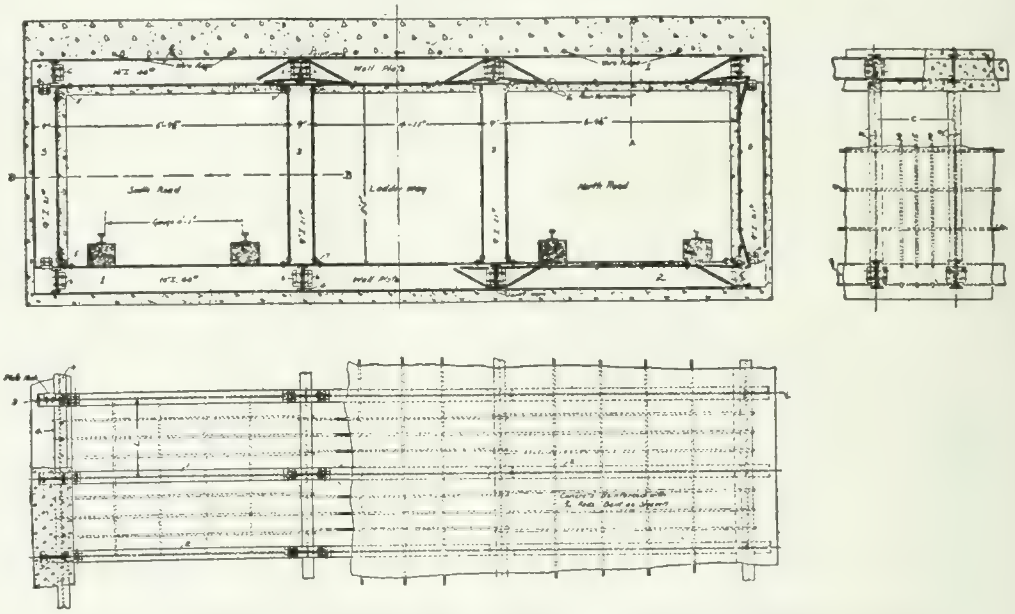

Fig. 1.—Details for Steel-Concrete Collar No. 2. Shaft Trimountain Mine, Plan and Elevation.

At the Trimountain mine it was decided to replace the old timber collars with concrete, and work was begun at No. 2 shaft, where the overburden was 80 ft. deep, consisting for the most part of sand, with more or less clay and some boulders. To guard against any possible "running" of the sand, and to make the operation of the shaft during construction easier, as well as to reinforce the concrete, it was decided to replace the timber with steel I-beam sets, and then concrete between and around the steel sets. The sets would provide a support in case it became necessary to put in lagging to hold back the sand before the concrete was placed. A foundation was first prepared at the ledge by placing heavy steel beam box girders across the shaft from foot to hanging under the dividers and under the south end plate. At the north end there was a natural rock ledge or shelf. Starting from the foundation thus formed the steel sets were built up, two or three at a time, and concreted in. The work proceeded as follows:

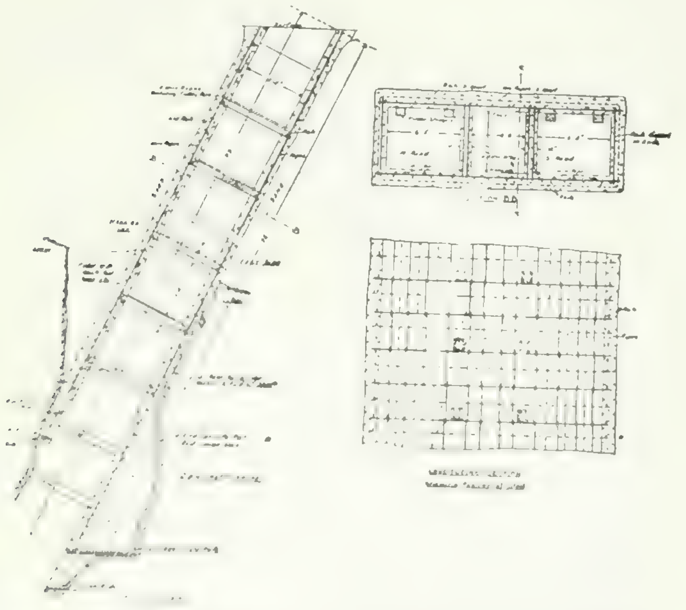

Fig. 2.—Reinforced Concrete Collar, No. 3 Shaft, Trimountain Mine.

First, the old timber on the ends and foot wall was taken out for as great a height as was deemed safe, then two or three of the steel sets were placed and bolted up, after which the forms were erected, and the concrete poured. Then another space would be opened up and the operation repeated, and so on until the surface was reached. Fortunately the old hanging-wall plates did not have to be removed, as there was sufficient clearance to permit the new concrete lining being carried inside of them. Care was taken to leave no timber or blocking under the foot-wall side of the concrete lining which might by rotting permit settling. The sand was carefully tamped along the foot wall as the concrete was finished. One skip road and the ladder way were built first, hoisting going on meanwhile in the other compartment. The skip was then changed over to the completed road, and the other road was built up. The steel sets were 2 ft. 4 ins. apart in the lower half of the collar, and 3 ft. apart in the upper half, centre to centre. The concrete between the sets was reinforced with ¾-inch rods, as shown by Fig. 1, which also shows the construction of the steel sets and the position of the concrete.

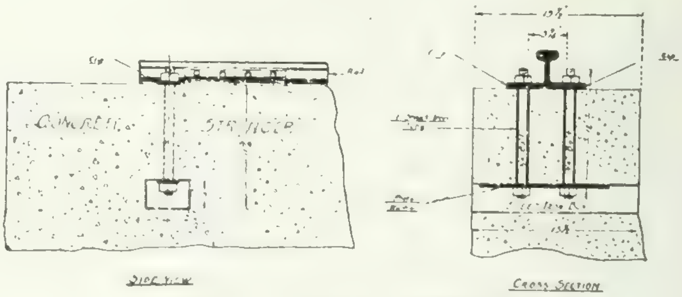

Fig. 3.—Details for Concrete Stringers, Showing Old Method of Fastening Rails.

The materials used for the concrete were: Portland cement, coarse amygdaloid stamp sand and crushed trap rock. They were mixed by hand in the proportion 1:3:5, in the shaft house just back of the shaft and lowered by a bucket and trolley, the trolley rope being concreted in on the hanging side as the work progressed. As no difficulty was experienced at No. 2 shaft with the sand running in, or otherwise, it was decided to build the Nos. 3 and 4 collars of reinforced concrete only, leaving out the steel sets. Fig. 2 shows the construction of the No. 3 collar, which was started in June, 1910, and finished in August, 1910. The materials for the concrete were the same and work was carried on in the same manner as at No. 2, except that there were no steel sets. The collar at No. 4 shaft was similar to the one at No. 3, except that the dividers were made 12 by 48 ins. instead of 12 by 12 ins. The overburden at No. 4 shaft was 128 ft. deep on the pitch of the shaft (71°), that at Nos. 3 and 2 being 60 and 80 ft. respectively; but in order to secure a suitable foundation, the No. 3 and No. 4 collars were started some distance below the ledge in the solid rock. The length of No. 3 collar was 93 ft. and of No. 4 was 158 ft.

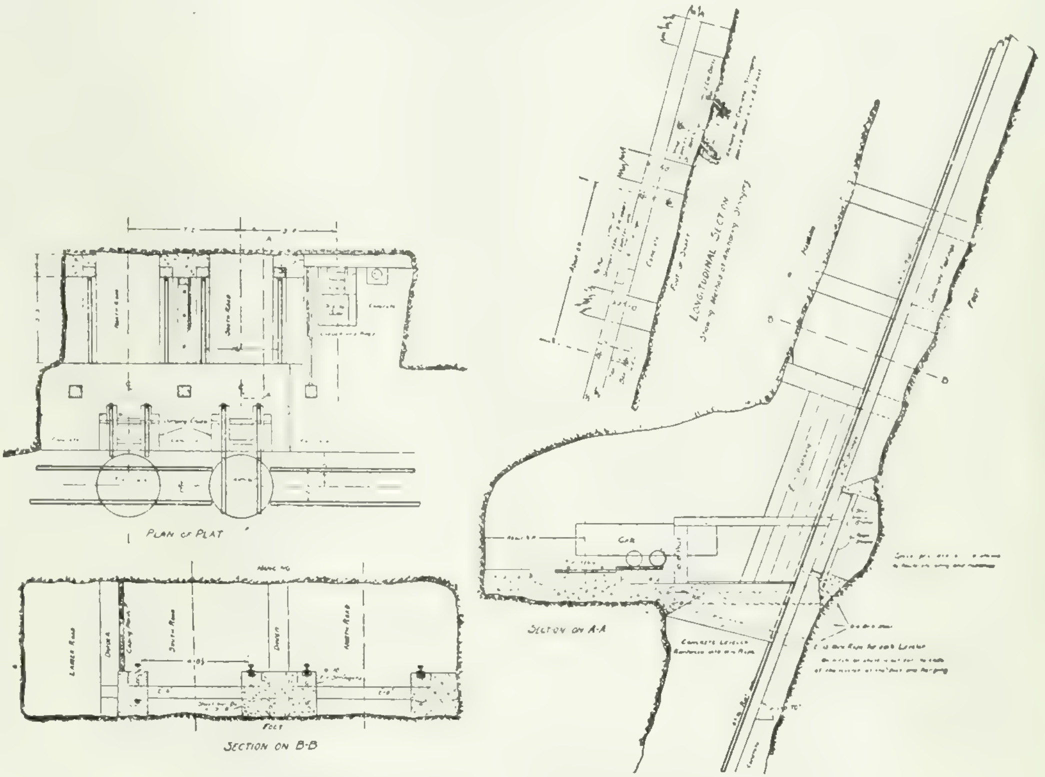

Fig. 4.—Underground Concrete Construction, Champion Mine.

Comparative Statement of Cost of Concrete Shaft Collars.

	No. 2 shaft.	No. 3 shaft.	No. 4 shaft.
Labor.			
Length, to foundation	80 ft.	93 ft.	158 ft.
Shaftmen	$2,019.10	$1,028.85	$1,994.70
Masons	528.51	......	......

Stamp sand, 3¼ cars No. 3.	......	45.70	......
Stamp sand, 8½ cars No. 4.	......	......	123.25
Fine rock, 3 cars..........	90.00	......	......
Sundry supplies	261.75	102.55	75.91
Freight	215.33	......	......
	$3,495.97	$ 619.05	$1,145.25
Total cost of shaft collars.	$7,293.92	$2,178.78	$3,521.04

No. 2 shaft collar commenced February, 1907, completed August, 1907.

No. 3 shaft collar commenced June, 1910, completed August, 1910.

No. 4 shaft collar commenced March, 1911, completed August, 1911.

Cost per ft.	Labor.	Supplies.	Total.
No. 2 shaft	$47.47	$43.70	$91.17
No. 3 shaft	16.77	16.66	23.43
No. 4 shaft	15.04	7.25	22.29

Fig. 4 shows a station or plat in one of the Champion Copper Company's shafts, and indicates the manner in which the levelers are reinforced. This illustration also shows the method used for concrete stringers. At first an all concrete stringer was built after the manner in use at the Ahmeek mine as designed by W. J. Uren, to which the rail was bolted by means of bolts and clips as shown in Fig. 3, but because

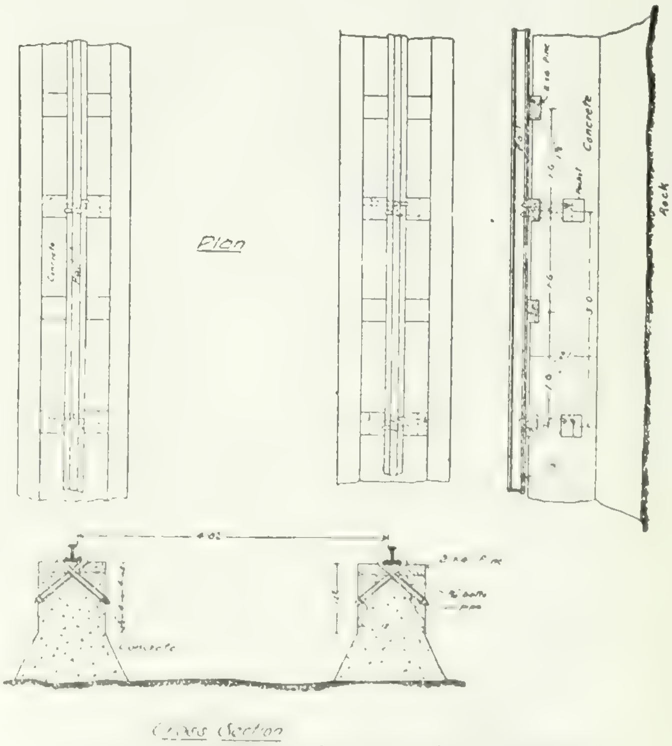

Fig. 5.—Concrete Stringers, Mohawk Method.

of the hard rigid roadbed thus formed the wear and tear on skip and rails was very great, and the bolts and clips were continually working loose. The scheme was therefore abandoned in favor of a combination wood and concrete stringer.

Fig. 4 shows the method in use at the Copper Range Con. Company's mines, and the Mohawk and Wolverine scheme is illustrated in Fig. 5. Both methods made a very satisfactory road bed.

At some of the mines where the foot is subject to "heaving" concrete stringers cannot be used advantageously.

In sinking through some loose ground at one of the Champion shafts it became necessary to close-timber, or line the shaft. Concrete 12 to 18 inches thick was put in, reinforced with old rails and wire rope. The concrete extended across the hanging and down on both ends, and sometimes across the foot, and there were also heavy concrete dividers 4 feet high by 10 inches thick, placed 10 or 12 feet apart. At several levels the whole plat was arched over with reinforced concrete. The lining has been in place about two years and has proven satisfactory.

Drift sets built of concrete have been tried to some extent at the Wolverine and Mohawk mines in some of their crosscuts where loose ground was encountered. These sets consisted of legs 6 by 6 inches in section, and a cap 6 by 8 inches, reinforced with ½-inch rods and wire rope. Concrete planks, reinforced with Kahn expanded metal, or woven wire, were used for lagging. Above the caps they were 4 by 14 inches in section and behind the legs 2½ by 14 inches.

The use of reinforced concrete in the form of shaft sets and lagging is well described in a paper read before the Michigan College of Mines Club, at Houghton, Mich., by E. R. Jones.

Concrete floors for shaft houses are being tried at several places and are proving satisfactory in many respects, although subjected to the hardest usage. The floors built at the Champion Copper Company's shaft houses were made 6 inches thick of 1:3:5 concrete, with a top finish 1-inch thick of 1 to 2 Portland cement and coarse stamp sand. The total cost was 13 cents per square foot. The materials used for the concrete were crushed trap rock, coarse stamp sand and Portland cement.

Question has been raised from time to time as to the suitableness of wire rope for reinforcement. Some tests of concrete beams reinforced with wire rope strands were made at the Baltic mine in 1910 by C. G. Mason.

◆

THE HETCH HETCHY WATER SUPPLY OF SAN FRANCISCO.

For the past ten years, the engineering force of the city of San Francisco has been scouring the State for possible means of future water supply. A dozen different projects have been examined, and the one which has seemed the most feasible is that of the Hetch Hetchy development, the principal reasons for this adoption being that of lower cost, more abundant supply and purer quality of water than any other obtainable. In May, 1908, the permit was obtained to use Lake Eleanor, situated near the Hetch Hetchy Valley, as a site for a storage reservoir, with further permission to use the Hetch Hetchy Valley when the limit of storage of Lake Eleanor had been reached. This latter permit was later called in question by the Department of the Interior, as two objections had been raised to its granting. The one was, that prior rights to the waters were being jeopardized, and the other that the natural beauty of a great scenic national park would be destroyed.

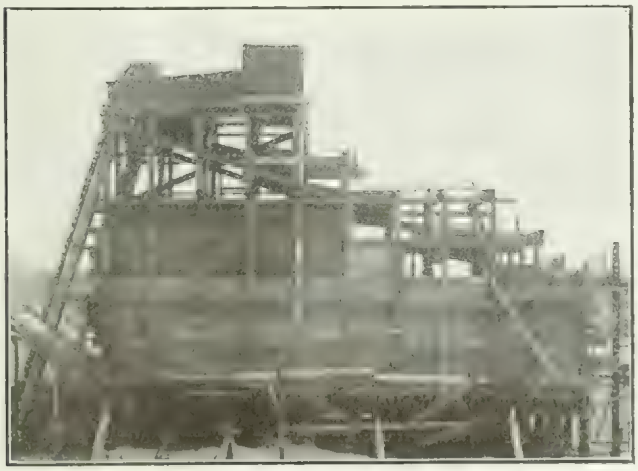
The first proposition, to bring these waters to San Francisco, outlined by C. E. Grunsky, engineer of the city of San Francisco, was to bring the water from Lake Eleanor and the Hetch Hetchy down across the San Joaquin Valley to Altamont. At this point he proposed to pump these waters over the coast range into San Francisco. The power for this pumping was to be gotten from power generated in the drop of the water from the Sierra Nevada side of the valley. During the last season, however, Mr. John R. Freeman, the noted water expert, has been called into consultation by the authorities in San Francisco to outline a comprehensive plan of development. Mr. Freeman's report is by far the most daring and all-comprehensive of municipal projects ever proposed. He has carefully estimated that by the year 2000 the population in the cities around the Bay, including San Francisco, Oakand, Berkeley, Richmond, Alameda, San Jose, Palo Alto, Redwood City and San Mateo will total 3,632,000, and will require a daily water supply of 441,000,000 gallons. In addition, it is proposed to obtain a supply of about 100,000,000 gallons a day for irrigating 95,000 acres. The general features of Mr. Freeman's scheme are as follows:—

A dam 300 ft. high is to be erected at the dam site of Hetch Hetchy by which the floor of the valley will be flooded to a depth of 270 ft.; a wagon road is to be built to Hetch Hetchy Valley equal in point of construction to the State highways with no grade exceeding 8 ft.; a scenic road is to be constructed at Hetch Hetchy Valley on both sides of the lake— this, as shown in the illustration, will make available the wonderful attractions of a region now inaccessible. And finally, the Hetch Hetchy aqueduct is to be built from this valley to San Francisco. This aqueduct will consist largely of a tunnel 10 ft. in diameter, for the most part deeply below the surface of the ground. This tunnel extends to the easterly edge of the San Joaquin Valley. Thence continuing westward across the valley, the suggested aqueduct will consist of one steel pipe 7 ft. 6 in. in diameter, and ultimately of two steel pipes side by side of similar proportions, about 45 miles in length. On the westerly side of the San Joaquin Valley the steel portion is to end about 8 miles westerly from the San Joaquin River. From this point the aqueduct proceeds westerly for the most part in the form of tunnels about 12 to 13 ft. in diameter to a point near the village of Irvington, at which point the terminal chamber and gate-house will be built, and branch aqueducts lead off as desired to Oakland, San Jose, San Francisco and other communities. From this point the aqueduct would proceed in the form of a steel pipe submerged across the Dumbarton Narrows near the head of the Bay, or it could be carried on dry ground around its head to a suitable point in San Mateo County, whence it could discharge by gravity at an elevation of 320 ft. through a new tunnel into Crystal Springs Reservoir or could feed branch lines leading to neighboring communities and to a main aqueduct line leading directly to San Francisco. The proposed aqueduct between Hetch Hetchy and the Irvington gate-house would be designed to deliver by force of gravity without pumping a quantity somewhat in excess of 400,000,000 gallons daily, equivalent to 620 ft. per second. All the tunnels will from the first be built to their full size and smoothly lined with concrete. During the early year, with only the single pipe line across the San Joaquin Valley, the delivery of the aqueduct would be in excess of 200,000,000 gallons daily, possibly 240,000,000. The branch line to supply the San Francisco peninsula will have a capacity of about 100,000,000. It is proposed to utilize the water until the population requires it for domestic use in the reclamation of arid land in and about the Bay region.

That portion of the tunnel, as shown in the illustration, which is about 12 miles in length and lays down stream from Hetch Hetchy, is to be delayed in construction for some years. Eventually, however, the construction of this tunnel will afford the development of 75,000 horse-power. At the point on the illustration marked "Power House No. 1" is seen a drop of 1,425 feet into Moccasin Creek, where 70,500 horse-power is developed. In addition to this it is proposed to construct a canal 8 ft. in diameter from the Hetch Hetchy Reservoir to the reservoir site in Cherry Valley, passing beneath the Lake Eleanor Reservoir site, with intake shafts at Cherry Creek and Lake Eleanor for the purpose of diverting their waters into the Hetch Hetchy reservoir. Only temporary dams are to be constructed at these two latter points, reserving for future demands a more permanent and substantial form of construction. The drop, as shown on the profile of this tunnel work, allows an additional development of power to the extent of 12,500 horse-power. Hence, in all, there is a total possible power development of 157,500. The entire project as proposed for immediate construction is estimated to cost $38,500,000. Mr. Freeman makes note of the fact that standing water tends to purify, and hence the purest supply of water is to be expected from this high Sierra construction. Indeed, he has stated in public before the Commonwealth Club, of San Francisco, that in comparing the softness of this supply to the softness of supply that might be developed from the Sacramento rivers, the saving in soap alone to the community about the Bay would eventually pay the interest on a $3,000,000 investment. To insure sanitary perfection and non-corrosion of the steel material in the pipe line, the pipe conduit is to be lined with concrete throughout its entire length.

A GRAVEL WASHING PLANT.

The gravel washing plant of the T. R. Nickson Company, which is shown in the illustration, is located within the business district of Vancouver, B.C., on the water front. Unwashed gravel is brought to the plant on barges, is washed and sized here, and delivered by teams as required in various parts of the city.



A Gravel Washing Plant at Vancouver, B.C.

As all towing is paid for by the yard, it is cheaper to bring in the raw material on barges than the sized, as in the former case, the fines fill the voids between the larger stones, allowing the unsized gravel to occupy about 20 per cent. less space and it is on this account that the plant is located within the city.

Gravel is unloaded from the barges by means of a grab bucket delivering into a receiving hopper at the plant. This hopper feeds an elevator, 56 feet centres, and equipped with 18 x 9 x 12-inch continuous buckets. The discharge from this elevator passes into a double chute feeding two rows of 54 inch Gilbert washing screens. These screens are all of the improved type, being provided with removable inner wearing skirts; these skirts increase the capacity of the screens and practically double the service of the outer screen plates. The typical arrangement of the screens in each row is adhered to, each screen successively separating the larger sizes into the bins and passing the fines and the water to the next screen. The last screens each deliver to a single discharge settling tank for separating the sand from the clay and loam in the water.

The first screens reject all the stone over two inches back to a jaw crusher below. This crusher delivers to a crusher elevator, 40 feet centres, with 9 x 9 x 9-inch continuous buckets, discharging to a small revolving screen. From here, the stone is passed to three bins, which supply the trade with crushed gravel.

All bins are equipped with swinging cut-off valves, which are operated from the wagons. These valves are balanced so as to be self-closing and they are consequently very easy to operate. They are entirely of cast iron, giving a very simple, rugged construction that can not get out of order and that can not choke up or spill.

This plant was designed and equipped by the Stephens-Adamson Manufacturing Company, of Aurora, Illinois.

CAUSE OF THE DESTRUCTION OF THE CANADIAN TAMARACK.

The almost total destruction of the tamarack, or larch, which took place throughout Eastern Canada almost thirty years ago, was caused by an insect, the Larch Sawfly. It appeared again about eight years ago, and in its spread westward it is repeating its former devastation on the younger tamaracks.

To all who are interested in our forests the appearance of a comprehensive account of this insect entitled "The Large Larch Sawfly, with an account of its Parasites, other Natural Enemies and Means of Control," by the Dominion entomologist, Dr. C. Gordon Hewitt, will be welcome. This has been published by the Dominion Department of Agriculture as Entomological Bulletin No. 5 and Bulletin No. 10 of the Second Series of the Experimental Farms Bulletins, and may be had free, on application to the Publications Branch, Department of Agriculture, Ottawa.

Dr. Hewitt has studied the life-history, habits and means of control of this injurious sawfly, both in England and North America. In England, it was found that the natural enemies, especially parasitic insects, effectively gained control of outbreaks of the insect. Other natural enemies were mice and birds and a system of bird encouragement was started on a large scale. The devastating spread of the sawfly in North America was due to the comparative absence of the natural means of control. Several important species of parasites new to science were discovered and have been studied and described. To increase the number of natural enemies of the sawfly, attempts are being made to introduce and establish in Canada parasites which were discovered in England and which appeared to control the pest there. An account of these interesting experiments and of the methods devised to encourage the birds and other means of control are described in this bulletin which consists of forty-two pages and contains twenty-six figures, including a colored plate. The publication of this bulletin is indicative of the attention which the Division of Entomology is now devoting to the insect pests of our forests which are responsible for incalculable loss each year.

COAST TO COAST.

Fort William, Ont.—David Johnson, a young clerk, was electrocuted in the show window of a men's furnishing store by an ordinary tungsten lamp when he was endeavoring to replace the broken light. It was only a 110-volt line. He died instantly.

Strathcona, Alta.—Extension lectures have been arranged in seven towns of Southern Alberta by the Department of Extension of the University of Alberta. These towns are Red Deer, High River, Macleod, Pincher Creek, Lethbridge, Taber and Medicine Hat.

Kaifers, B.C.—The entire top of a section of Jackass Mountain, opposite this place, on the line of the C.P.R., collapsed a few days ago, hurling into the Fraser River hundreds of thousands of cubic yards of rock, ruining a 249-foot tunnel of the C.P.R. The slide made a noise that was heard for miles. No lives were lost.

Toronto, Ont.—The employees of the Consumers' Gas Company, this city, are to be afforded the opportunities and benefits of a course of training along the lines of salesmanship and general education. This company recently joined the membership of the National Commercial Gas Association and in this connection the employees are entitled to instruction from the correspondence department of the parent offices.

Moose Jaw, Sask.—City Engineer Antonisen, after an inspection of the mines and property of the Consumers' Coal Company, has stated that a supply of coal for economical power purposes may be secured from the areas of coal south of this city. His plan includes the erection of a power plant at the mines and the construction of a high-voltage transmission line into a municipal step-down station. It is reported that there are ten million tons of coal easy of access in this region.

Provinces of Ontario and Quebec.—A deputation of five representing the Ontario Government, occupied seats on the floor of the Legislative Assembly, November 27th, to confer with the government regarding certain suggestions that have been made for the celebration of the peace century between Canada and the United States. The members of this deputation were Hon. Jas. Duff, Minister of Agriculture; the Hon. Mr. Reaume, Minister of Public Works; Mr. John G. Kent and Dr. J. O. Orr. They were entertained by the Speaker, Hon. Mr. Delage.

Hamilton, Ont.—City Engineer A. Macallum has submitted to the works committee a plan for a cross-city flood sewer. He said the cost of sewer to cover 75 per cent. of the district would be $360,000, and to cover 95 per cent. $596,679. Controller Allan suggested that if the sewer project were in shape they could submit a by-law to the people to raise money at the same time as the Hydro-Electric Commission was to be elected, in May. The city engineer also submitted plans for improving the sewage disposal works in the east end, and was instructed to submit them to an expert.

Ottawa, Ont.—The Board of Railway Commissioners of Canada have issued specifications dealing with the erection of highway crossing signals. They are as follows: The signal must be placed upon a post of suitable structural material. If the post is made of wood, it must be of sound timber not less than 8 x 8 inches and 18 feet long, and shall be firmly set in the ground to a depth of four feet. If it is made of iron or steel, it shall be not less than 4 inches in diameter, shall extend at least twelve feet above the ground, and shall be firmly bolted to a concrete or other foundation constructed below the frost line. A bell which shall emit a clear, loud volume of sound under all weather conditions must be used. A sign shall be placed upon the same post as the bell, with the word "danger" upon it in letters not less than 6 inches in length, to be illuminated, so as to be plainly visible after sunset. There may be added to the post, if so desired, the railway crossing sign provided for by Section 243 of the Railway Act.

Regina, Sask.—The proposal to divert water from the South Saskatchewan River to supply the needs of Regina, Moose Jaw and many of the towns to the southern part of the province has been taken up by the Federal Government. It will be remembered that during the latter part of last year and the early part of this the Provincial Government had T. Aird Murray, consulting engineer, of Toronto, go into the question fully and it is understood his report was favorable to the furtherance of the scheme. The Federal Government has three parties of men at the Elbow and Tugaske to take levels at the river bend, about thirty miles west of Elbow, and to secure other information relative to the matter. H. E. M. Kensitt, the inspector of the water powers branch, Department of the Interior, has been in charge of the work. It is understood that all the preliminary work has been completed, and it is expected that an official statement concerning the matter will be given out within the near future. To carry out the proposed scheme would require the laying of a pipe line about 140 to 170 miles in length, according to a statement made by Mr. Kensitt, and the cost would be between $5,000,000 and $7,000,000.

Ottawa, Ont.—Judge Gunn's report on the recent waterworks investigation was received by the city council on December 2nd. It places the blame for the typhoid epidemic on the waterworks coimmittee, board of health, City Engineer Ker, and Medical Health Officer Sherreff. The waterworks committees from 1908 to 1912 are censured for failure to give their duties the consideration warranted by their importance. The board of health is held responsible through failure to undertake earlier investigation of the polluted water situation. Judge Gunn says: "I place on the committees of 1910-11 the responsibility for the conditions of the steel and concrete piers, because these committees were in a position to exact that the new pipe be tested and laid by experienced workmen, and I regard that testing and laying of the new pipe, steel and concrete as the most important element to be considered in this investigation. Because of the many new duties thrown upon him by the Public Health Act, I do not consider that the present medical health officer will, to his own or to the satisfaction of the citizens, find that office acceptible, and a grave injustice was, in my opinion, done Dr. Sherreff when he was placed by his friends and supporters in a position that was in every way a difficult and most trying one. I unhesitatingly acquit of any irregularity or attempt other than lawful means to secure his appointment. The appointments to the board of health should not be made for the purpose of giving municipal office to an ex-alderman or prominent citizen who has no other qualifications. I would recommend that in order that the new council might have a free hand in the reorganizing of the department, these gentlemen, (present members with terms still to run) throw up the seals of office."

PACIFIC COAST COLLIERIES.

The Pacific Coast Collieries, Limited, has been formed with capital of $3,500,000 bonds, $1,500,000 6 per cent. preferred stock, and $3,500,000 common stock, which has taken over the Pacific Coast Coal Mines, Limited.

LARGE PIPE FITTINGS.

Three special fittings of large size have just been made for the Crane Falls Power and Irrigation Company, of Caldwell, Idaho.

The three cast-iron bell-end fittings have a combined weight of 19,150 pounds, the larger one in the figure weighing 10,850 pounds, the smaller one 4,200 pounds, and the third 4,100 pounds.

View of Large Fitting.

The dimensions are, respectively: 5 feet with three 24-inch flanged outlets. 4 feet 4½ inches with two 24-inch flanged outlets, and 3 feet 10 inches with two 18-inch flanged outlets.

These are all discharge fittings for pumps and were ordered through the Portland branch of Crane Co. by Smith, Kerry & Chase, engineers for the power and irrigation company. The fittings connect at the bell-end to wood pipe and at the flanged ends to spiral steel pipe penstocks. The largest fitting will work under a static head of 159 feet, the next in size under a head of 89 feet, and the smallest under a head of 54 feet.

◆

PERSONAL.

E. L. COUSINS, B.A.Sc., harbor engineer for the Toronto Harbor Commission, delivered an address to the Toronto branch of the Canadian Society of Civil Engineers on Thursday evening, November 28th, on the new plans for Toronto harbor. The meeting was very well attended, about one hundred and fifty being present.

ARTHUR H. BLANCHARD, M. Can. Soc. C.E., professor of highway engineering in Columbia University, on November 25th delivered an address entitled "The Art and Science of Highway Engineering" at the celebration of Founders' Day at the Clarkson School of Technology.

STANLEY M. OBORN, who is in the main drainage department of the Department of Works, Toronto, has been elected an Assoc. M. Can. Soc. C.E. Mr. Oborn has had a varied experience in municipal engineering in England, and has been in Canada about six months.

JOSEPH OWEN, of London, England, has been appointed assistant to Mr. John Wilson, city engineer, of Fort William Ont.

JAMES WALKER, Assoc. M. Inst. C.E., M.I. Mech. E., we are informed, is about to join the staff of Messrs. Boving & Company, Limited, water power engineers, of 9½ Union Court, E.C., and will also join the board of directors. After a long and extensive experience with the contracting firm of Messrs. S. Pearson & Son, of Westminster, he was engaged by Messrs. J. G. White & Company, Limited, of 9 Cloak Lane, E.C., with whom he has been for the last nine years, acting as construction superintendent on large works abroad, and latterly as engineer in charge of construction in the head office in London. With his wide experience in hydro-electric undertakings and civil engineering work in general, he will undoubtedly be a great acquisition to the firm in its already large and rapidly increasing business. It will also interest our readers to learn that Mr. Reginald K. Morcom has also consented to act on the board of Messrs. Boving & Company.

VIRGIL G. BOGUE, a New York engineer, has been retained in a consulting capacity by the Canadian Pacific Railway in connection with double-tracking of the main line between Vancouver and Calgary.

Hon. Robert Rogers, Minister of Public Works.

◆

MEETINGS.

Mr. C. C. Cariss, of E. Leonard & Sons, lectured on the "Clayton, Logarithic Analysis of Cylinder Performance" before a large audience at London, Ont. Mr. Cariss showed how improved performance could be obtained from steam and other heat engines by improved methods of indicator diagram analysis.

◆

OBITUARY.

JAMES M. SHANLEY, one of the best known civil engineers in Canada, died on November 28th, at Montreal. The deceased was born in Illinois 55 years ago, but came to Canada at an early age. He was educated at Galt Collegiate Institute and Toronto University. After graduating he started practising in Montreal. One of the first pieces of work done by the late Mr. Shanley was in connection with the Beauharnois Junction Railway, now a part of the New York Central's road into Montreal. He is survived by Mrs.

Shanley, who is a daughter of Mr. Robert Conroy, of Aylmer, three sons and three daughters.

C. W. LEONARD, of the firm of E. Leonard and Sons, of London, Canada, passed away on November 22. Mr. Leonard was born in 1852 and at the time of his death was just 60 years old. He was educated in the London public schools, and at Upper Canada College. After completing his course at the latter institution he entered the employment of his father, the late Senator Elijah Leonard. Later on he was admitted to partnership, and after the death of his father, Mr. Leonard and his brother carried on the business under the name of E. Leonard & Sons. Mr. Leonard's death, which was due to heart failure, was very sudden, as he had been at work in the office the night before until nearly 6 o'clock, as usual. He is survived by his widow and one daughter, Mrs. Dr. Fitzgerald, of California.

COMING MEETINGS.

CANADIAN SOCIETY OF ENGINEERS.—Mechanical Section Meeting will be held in the rooms of the Society, 413 Dorchester Street West, Montreal, December 5th, 1912. Chairman, H. H. Vaughan.

NATIONAL ASSOCIATION OF CEMENT USERS.—December 12th to 18th. Annual Convention, Pittsburgh, Pa. President R. L. Humphrey, Harrison Building, Philadelphia, Pa.

UNION OF MANITOBA MUNICIPALITIES.—Programme for Ninth Annual Convention to be held in Convention Hall of the Industrial Bureau, Winnipeg, Nov. 26, 27, 28, 1912. Secretary, Reeve Cardale, Oak River, Man.

AMERICAN WOOD PRESERVERS' ASSOCIATION.—Ninth Annual Convention will be held at Chicago Jan. 21-23, 1913. Secy-Treasurer, F. J. Angier, Mount Royal Station, B. & O. R. R., Baltimore, Md.

AMERICAN INSTITUTE OF CONSULTING ENGINEERS.—Annual Meeting, January 14th, 1912, will be held at The Engineers Club, 32 West Fortieth Street, New York, N.Y. Secretary, Eugene W. Stern, 103 Park Avenue, New York.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. Secretary, E. L. Power, 150 Nassau St., New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W. Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh B. Fergusson, 911 Rogers Building, Vancouver, B.C. Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack. Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor, Secretary-Treasurer Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

Place of Work.	Tenders Close.	Issue of	Page.
Edmonton, Alta., paving	Dec. 10.	Nov. 21.	74
Kamloops, B.C., steam power station equipment	Dec. 5.	Nov. 21.	76

Winnipeg, Man., plans for city hall	Feb. 15.	Sept. 26.	68
Winnipeg, Man., turbines and governors	Dec. 16	Nov. 28.	66

TENDERS.

Bassano, Alta.—George B. R. Bond, secretary-treasurer of the corporation of this town, will receive sealed tenders, accompanied by a marked cheque equal to 5 per cent. of the tender price, up to 8 p.m., Monday, December 9th, next, for the following work:—

Contract T—All labor and materials for constructing a concrete pump shaft, 130 feet deep, and laying 18-inch steel intake pipe in tunnel from shaft to Bow River, 225 feet in length, and constructing intake crib in river.

Contract H—All labor and materials for constructing frame power house at Bow River.

Contract F—All labor and materials for constructing frame frost casing for stand-pipe, 25 feet in diameter and 112 feet high.

Plans and specifications for all contracts may be obtained from the John Galt Engineering Co., Limited, Winnipeg and Calgary, on deposit of cheque for $10, which will be returned to bona fide tenderers.

Province of British Columbia.—Mr. P. Welch, railway contractor, has recently awarded a number of sub-contracts for the construction of the Pacific and Great Eastern Railway.

Dunnville, Ont.—Messrs. Heap and Partners, Montreal, have been awarded a contract for the installation of turbine pumps as required by this municipality.

Eau, Ont.—The management of the Lake Erie Coal Company have awarded a contract to Messrs. Morgan & Tifft for the erection of a roundhouse and other buildings at this point, which is not far from London.

Kamloops, B.C.—The date for receiving tenders, steam, pumping and electrical equipment for the new civic power house, has been extended to December 19th, 1912. (See advertisement in Canadian Engineer.)

Moncton, N.B.—Sealed tenders, addressed to L. K. Jones, Esq., Assistant Deputy Minister and Secretary, Department of Railways and Canals, Ottawa, and marked on the outside, "Tender Freight Car Repair Shop, Moncton," will be received up to and including Monday, December 16th, 1912, for the construction of an addition to the freight car repair shop at Moncton, N.B. Plans and specification may be seen at the office of the above and at the office of the Engineer of Maintenance, Moncton, N.B., at which places forms of tender may be obtained.

Ottawa, Ont.—R. C. Desrochers, Secretary Department of Public Works, will receive sealed tenders up to 4 p.m. Monday, December 30th next for the supply of machinery for a 3½ yard dipper dredge. (See full particulars in Canadian Engineer, advertising section.)

Quebec, P.Q.—R. C. Desrochers, Secretary Department of Public Works, Ottawa, will receive sealed tenders for the erection of an addition and certain alterations to the Central Post Office, Quebec, P.Q., up to 4 p.m. on Monday, December 23rd next. (See advertisement in Canadian Engineer.)

Toronto, Ont.—The municipal Board of Control will receive tenders for supplies up to noon December 10th, 1912, (See full particulars in the advertising section of this paper.)

Vancouver, B.C.—Sealed tenders for the construction and engining of two twin-screw steamers, 95 ft. long, 18 ft. beam and 9 ft. depth, fitted with triple-expansion, surface-condensing steam engines and water tube boilers, will be received up to December 12th next by the West Vancouver Ferry Board, care of Messrs. Morris, Bulkeley & Halliday, Vancouver. The plans, specifications and conditions of contract may be obtained from Messrs. Morris, Bulkeley & Halliday, naval architects, 610 North-West Trust Building, Vancouver, on payment of fee of $5. Separate tenders will be considered for the construction of the hulls, and for the machinery and installation, but preference will be given to firms who will undertake the building and equipping of both vessels complete.

Yorkton, Sask.—The contract for the equipment of the electrical plant for this town (pending certain changes in the financial aspect of the deal) have been awarded to the following companies: Canadian Boving Company, Diesel engine; Westinghouse Company, switchboard; Siemens Company, alterator and exciter. The cost of this work is given at $39,453.30.

CONTRACTS AWARDED.

Ottawa, Ont.—The Wm. Hamilton Company, of Peterborough, Ont., will supply two boilers or apparatus needed here for thawing out frozen water services. Their tender of $427 for the total was the lowest.

Port Arthur, Ont.—The contract for the construction of a breakwater at this point has been awarded to the Thunder Bay Contracting Company, Limited, of Port Arthur. The price is not made public.

St. Boniface, Man.—The contract for the furnishing and installation of a motor and motor-driven pump, as required by this municipality, has been awarded to the Canada Foundry Company, of Winnipeg, at a price of $2,732. Other bidders were the John McDougal Caledonian Iron Works, Limited, Montreal; Escher, Wyss & Co., Montreal; Heap & Partners, Limited, Montreal; Chapman and Walker, Montreal and Winnipeg; Drummond McCall & Co., Montreal; Goold Engineering Co., Winnipeg.

RAILWAYS—STEAM AND ELECTRIC.

Edmonton, Alta.—The civic railway department are considering the extension of the car tracks in a northerly direction.

Montreal, P.Q.—The Canadian Pacific Railway will spend $48,000,000 in new rolling stock.

North-Eastern Ontario.—It is reported that the Grand Trunk Pacific Railway has entered an agreement with the North Railway Company whereby the Grand Trunk Railway will secure running rights over that line from Montreal to the Bell River, where the North Railway crosses the Transcontinental 250 miles from Montreal and half way to the James Bay.

Province of Saskatchewan.—Railroad construction during the last half decade has added 2,847 miles to the lines in this province.

Toronto, Ont.—The operation of the Temiskaming and Northern Ontario Railroad for the twelve months ending October 31st last resulted in a balance of $510,000 to the credit of earnings. This is $10,000 in excess of expectations.

◆

LIGHT, HEAT AND POWER.

Fort William, Ont.—Mr. M. O. Robinson, manager of the joint board of street railway commissioners, has stated that the power-house in this city is working at maximum output, and if additional cars are required a sub-station and generator will have to be added to the service.

Lindsay, Ont.—The Light, Heat and Power Company have been instructed to install ten additional arc lamps on the streets of this town.

New Westminster, B.C.—Application for extensive water rights on Brandt Creek, Indian River, Young Lake and Norton Lake are to be made very shortly by the New Westminster Power Co., Limited, as a preliminary to the establishment and erection of a power plant to supply the Fraser Valley district with current for lighting and power purposes. The New Westminster Power Company is composed of a number of local parties backed by English capital.

Regina, Sask.—Mr. Wynne-Roberts has reported that the two thousand million tons of lignite in the southern portion of this province is suitable for power production.

St. Thomas, Ont.—It is reported that the Hydro-Electric department of this city has 4,800 consumers.

◆

GARBAGE, SEWAGE AND WATER.

Arcola, Sask.—The Canadian Pacific Railway surveyors have located a desirable source of water supply for this town in the Moose Mountains, a distance of ten miles. This railway have planned extensive developments at this point, and it is probable that the water will be piped into the town.

Brantford, Ont.—The municipal water commissioners are considering the extension of the waterworks as required by the fire underwriters. The cost of this work is estimated at $150,000, and this includes considerable iron pipe.

Calgary, Alta.—The municipal council have been asked to approve the purchase of a motor-driven pump of 10,000,000 gallons capacity. This is to be placed one mile west of the present pumping plant and will cost $20,000.

Hamilton, Ont.—There is a probability of the council appointing an engineer to prepare a report on the matter of sewage and sanitation now before the consideration of the authorities.

London, Ont.—Mr. Willis Chipman, of Toronto, is examining and checking the plans, already prepared, for a storm sewer system for this city.

Ottawa, Ont.—The civic incinerator is now operating under a test which is likely to continue for about two weeks.

Ottawa, Ont.—The plans for the Ottawa filtration plant have been unanimously approved by the Provincial Board of Health.

BUILDINGS AND INDUSTRIAL WORKS.

Estevan, Sask.—Mr. Geo. Barr, of Gladstone, Sask., will erect a plant at this point for the manufacture of bricks.

Fredericton, N.B.—According to an announcement recently made by Hon. John Morrissy, Chief Commissioner of Public Works, a large addition will be added to the Normal School in this city in the spring of 1913. This work will cost about $35,000.

Guelph, Ont.—The ratepayers will be asked to vote the sum of $15,000 to be used in the erection of a fire hall and equipment for the same. T. J. Moore is clerk of this municipality.

Hamilton, Ont.—Mr. Griffin, well-known theatre owner, states his intention of erecting a $75,000 playhouse in this city.

London, Ont.—The Eisendrath Glove Company, of Chicago, will establish a branch factory in this city.

Medicine Hat, Alta.—The Alberta and Saskatchewan Paper and Strawboard Products Co., Limited, of Calgary, will erect a factory in Medicine Hat. It will cost in the neighborhood of $150,000. Messrs. C. F. Schaub and F. A. Burton, Calgary, are directors of the company.

Medicine Hat, Alta.—Mr. J. H. Tabor, of Calgary, is a member of a recently formed company that are about to erect a plant in this city for the manufacture of confectionery.

Montreal, P.Q.—The various athletic associations of McGill University are agitating for the erection of a modern dressing-room with all suitable fittings, such as steel lockers, etc.

Montreal, P.Q.—Messrs. Putnam and McCrory were agents for parties who purchased a site fronting on Dominion Square with the intention of erecting a large hotel.

Norwich, Ont.—The Dominion Canners according to report, will establish a large factory at this point.

Regina, Sask.—The Minneapolis Threshing Company, of Minneapolis, Minn., U.S.A., will erect a plant in this city for the manufacture of their products. Mr. T. H. Roney is in charge of the branch office.

Sault Ste. Marie, Ont.—The steel plant of the Lake Superior Corporation is to be greatly extended at once at a cost of several millions. Another blast furnace will be built and the coking plant increased. Mr. J. Fraser Taylor is an official of this company.

South Vancouver, B.C.—Mr. Walter Thomas is negotiating for the installation of a gas plant in this municipality.

St. Catharines, Ont.—Griffin's family theatre is to be enlarged to double the present dimensions.

St. Thomas, Ont.—The management of the Erie Iron Works have notified certain contractors of their intention to call tenders for the enlargement of their works. Much new machinery is also to be purchased.

Toronto, Ont.—The Civic Works Commission have voted the sum of $147,420 to be expended in additions to the plant for the roadway and sewer sections of the engineering department.

Vancouver, B.C.—Tenders for the erection of a five-story mill construction stores and apartment building on Robson Street, near the corner of Thurlow, to cost about $100,000, will be called for soon. Mr. Emil Guenther is the architect for this building.

Victoria, B.C.—The British Columbia Electric Railway Company will erect terminal facilities in this city to facilitate the operation of their line to Saanich.

Weyburn, Sask.—The management of the Weyburn Sash, Door and Glass Company will increase their present plant

Copies of The Canadian Engineer dated October 24th, Volume 23, No. 17, and November 14th, Volume 23, No. 20, 1912 are required. Subscribers sending in copies will have their subscriptions extended one month without extra charge.

Barrett Specification Roofs

A Mile of Barrett Specification Roofs

The wonderful Bush Terminal in Brooklyn, New York, illustrated below, includes 181 buildings, comprising tremendous warehouses, enormous pier sheds for docking ocean steamers, huge factory buildings, a large modern power house and an enormous freight structure. These buildings stretch for a mile along New York harbor. Their total roof area is 3,100,000 square feet—more than seventy acres.

The entire area was covered with Barrett Specification type of roofs, for the following reasons:

1. Low first cost.
2. No maintenance expense, such as painting, etc.
3. They are not injured by steam, gases and acid fumes.
4. They are fire retardent and take the base rate of insurance.
5. The net unit cost, that is, the cost per foot per year of service, is lower than that of any other type.

Although some of the buildings are fifteen years old, the roofing contractor states that the expense for maintenance of this entire roof area has been less than $10.00. He estimates that if metal or ready roofings had been used, it would have been impossible to keep the buildings free from leaks and that the painting bill alone up to date would probably have amounted to at least $50,000.00.

We wrote to the Bush Terminal Company, asking what they thought about Barrett Specification Roofs. The Vice-President replied:

> "We use this kind of roofing because our experience has shown it to be the best and cheapest. Our analysis of first cost of application and cost of maintenance entitles us to speak with some measure of authority."

We shall be pleased to mail architects, engineers or owners of buildings copy of the Barrett Specifications with diagrams from which blue prints can be made. Address our nearest office.

Special Note

We advise incorporating into plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired, however, the following is suggested.

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15, 1911, using the materials specified, and subject to the inspection requirements.

THE PATERSON MANUFACTURING CO., LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER ST. JOHN, N.B. HALIFAX, N.S.

BRIDGES, ROADS AND PAVEMENTS.

Calgary, Alta.—The ratepayers endorsed a by-law calling for the erection of a high-level bridge across the Bow River, together with two smaller structures. Eight hundred thousand dollars is the preliminary estimate, but the actual cost of this work will be almost $1,000,000 before completion.

Calgary, Alta.—The municipal council propose to charge a rate of $2.10 against property owners benefiting from pavements laid from the new civic plant. The net cost of this work is $2.02 which leaves a gain of $2,192.63 from one year's operation.

Fort Francis, Ont.—The Board of Trade of this municipality are arranging with the Ontario Crown Lands Department for the construction of a highway between this point and Rainy River. The cost of this work is estimated at $200,000 for the sixty-mile stretch, and if completed will give one of the best automobile and wagon roads in Canada. J. F. Whitson is chief engineer of this department.

Moose Jaw, Sask.—It is reported that the proposal to divert the South Saskatchewan River to Regina and Moose Jaw is receiving considerable attention from the Federal government.

Toronto, Ont.—Owing to indications of inferiority in the creosote-treated wood blocks that have been supplied to the engineering department of this city the department will purchase blocks of southern pine and treat them before laying in order that a comparison may be established. R. C. Harris, Commissioner of Works.

Toronto, Ont.—Works Commissioner Harris has been given authority to call tenders for a stone quarry containing suitable materials for road construction in the recently acquired sections of this city.

Victoria, B.C.—A report, dated November 27th, states that street paving work has closed for the winter in this section of the country.

◆

FIRES.

Bremner, Alta.—A large elevator at Bremner, fourteen miles east of Edmonton, the property of the Alberta Grain Company, was totally destroyed by fire. Over 11,000 bushels of grain was consumed.

Dryden, Ont.—Fire destroyed the power house and sluice-gates of the Dryden Timber and Pulp Company November 28th, entailing a loss of $100,000. The loss falls on Harris & Harris, contractors, Toronto, who had about completed work.

◆

CURRENT NEWS.

Province of British Columbia.—Telegraphic communication has been established by the Government line between Fort George, on the Grand Trunk Pacific main line, and Stuart Lake, the old Hudson Bay post of Fort St. James, a distance of about 60 miles, thus marking another step in the progress of development in the central interior of British Columbia. The rate on this new line will be 75 cents for a 10-word message and 5 cents a word for every additional word.

Calgary, Alta.—Dr. Mahood, recently appointed Medical Health Officer for this city, is to make a strenuous effort to have all possible places of contagion eradicated. He will direct his first efforts toward several doubtful eating houses.

Edmonton, Alta.—It is reported that contracts for 511,533 square yards of paving will be awarded about December 16th.

Galt, Ont.—It is reported that the Board of Health will appoint a sanitary inspector.

Hamilton, Ont.—Certain aldermen are negotiating for a revolution in the method of conducting business at the city hall. Alderman Horning, who is interested in the matter, declares that the present system is years out of date, and what is needed is modern methods of system and office appliances for the proper working of the various offices.

Hamilton, Ont.—Alderman Newlands has been making some slight investigation into the amount of work accomplished by the average civic laborer, and has stated one or two instances which would tend to show lack of organization in this department.

Hull, P.Q.—A delegation from this city have requested assistance in the proposed erection of a technical school.

TRADE ENQUIRIES.

The following were among the enquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending 18th November 1912:—

A co-operative shipping agency in Ireland make enquiry for the names of reliable shippers of wood in Canada suitable for the manufacture of butter boxes.

A correspondent in North Wales, interested in several slate quarries, is desirous of opening a market in Canada for roofing slates, and would like to hear from importers.

A well-known Lancashire firm of solid woven belting manufacturers desire to appoint a first-class Canadian agent.

A London correspondent, stated to be interested in a new tree-felling device, makes enquiry for names of Canadian lumber firms.

A North of England firm manufacturing filtering cloths for all kinds of oils, for paper soap, paint and varnish, glue and porcelain manufacturers, sugar refiners, flour millers, etc., and specializing in a feed-water heater filter cloth for marine and land engines, wish to enter the Canadian market.

A West of England firm of architectural metal workers, who make electric light fittings, and every kind of ornamental metal work, wish to appoint a reliable agent to represent them in Canada.

Enquiry is made by a firm at Copenhagen for the names of Canadian agricultural implement manufacturers desirous of doing business in Scandinavia.

A Montreal firm of leather merchants are in the market for supplies of best worsted, cheviot, vicuna and beaver cloths, and would like to receive quotations and samples from United Kingdom manufacturers.

From the branch for city trade enquiries, 73 Basinghall Street, E.C.:—

A London firm which does the whole of the buying for its branches in Cape Town, Johannesburg, and Port Elizabeth, would be pleased to get into touch with Canadian manufacturers of lines suitable for the South African market. These include agricultural machinery and implements, printing and wrapping paper, stationery, furniture, hardware, brushes, paints, wearing apparel, boots, etc.

The London manufacturers of a patented wire netting fastening machine seek suitable Canadian resident agents

◆

DISSOLUTION OF PARTNERSHIP.

The firm known as Vandeleur and Nichols, Dineen Building, Toronto, Ont., comprising Mr. J. B. Vandeleur and Mr. R. H. Nichols, is in process of dissolution. The business, however, has been actively managed by Mr. Nichols for the past few months, and it is the intention of Mr. Nichols to carry on business in the same lines as heretofore.

◆

WITH THE FAIRBANKS-MORSE COMPANY.

Mr. Cyril J. Atkinson, M. I. Mech. E., inventor and patentee of the Atkinson gas producer and a number of special devices pertaining to gas producers, has severed his connection with the Dornfeld-Kunert Company, of Watertown, Wisconsin.

Mr. Atkinson's services and the use of all his patents have been secured by Fairbanks-Morse & Co., and a number of Mr. Atkinson's valuable patents will be incorporated in the Fairbanks-Morse gas producers at once. This company will place Mr. Atkinson's services at the disposal of the public for adapting the Fairbanks-Morse gas producers to meet the requirements of the various industries desiring to substitute producer gas for fuel oil. This will be of particular service and effect large economies in forge shops, malleable iron foundries, galvanizing plants, enameling works, brass foundries, etc.

◆

The Tiffin Wagon Company of Tiffin, Ohio, who have manufactured for many years a complete line of dump wagons and carts, are commencing to build motor trucks. The company expect to be ready to supply trucks for spring delivery. They are represented in Montreal, Toronto and Vancouver by Messrs. Francis Hankin & Company.

RAILROAD WORK IN THE ARGENTINE.

J. G. White & Company, Inc., have just received telegraphic advice of the award to their London associates (J. G. White and Company, Limited), of railroad construction work in the Argentine, amounting to about $4,000,000, from clients for whom they have carried out several previous contracts; this new contract, like the others, being on their usual basis of cost plus a fee.

The railroad to be constructed constitutes the connecting link in the through system between Brazil and the Argentine Republic, the terminal at Buenos Aires and Rio de Janeiro.

◆

RECENT ADDITIONS TO FACTORY OF VICTOR BALATA AND TEXTILE BELTING COMPANY, EASTON, PA.

It is the exception rather than the rule that manufacturers are compelled to increase their production facilities during the year of a Presidential election. Heretofore the general rule has been to curtail expenses and await the immediate developments following a change of administration, and consequently a change of policy.

While business in general during the past six to eight months has been hardly more than normal it is a matter of considerable gratification that the Victor-Balata and Textile Belting Company, of New York city and Chicago, with factories in Easton, Pa., has been compelled to build additions with added machinery to its already large textile factories where Victor-Balata and Victory and Ampere canvas-stitched belting are made.

It is generally well known that increased facilities, more machinery, etc., have been forced by the rapidly increasing demand for Victor-Balata belting since it has been made in America, and the many friends of the company will be pleased to learn of the much-needed factory increase now in the course of construction, in the canvas-stitched belting department to accommodate the expanding trade in this particular line.

This pleasing condition has been brought about by universal recognition of the superior points of excellence contained in the two noted brands—Victory and Ampere. The ordinary lines of canvas-stitched belting on the market have nothing of especial significance to commend them to the buyers, and the selling proposition is one where "all belts look alike," and simply a matter of "price" or of personal influence, or both.

Both Victory and Ampere canvas-stitched belting have characteristic points of construction that place them in a distinctive class by themselves, commending them to discriminating buyers, who purchase on a "quality" basis and not on price only.

The principal points of excellence are the inside hardened edges, the absence of undesirable stretch, and the special impregnation and painting processes, these latter being two entirely separate processes, thus allowing the use of different ingredients for impregnating and painting, in contrast to the one mixture and one process common to other makes of canvas-stitched belting. The inside hardened edges of Victory and Ampere canvas-stitched belting allow it to be used for drives requiring shifters which are harmful to the edges of belting. The hardened edges prevent the belting from fraying out, tearing, etc., when the edges come in contact with parts of machinery, installation work, etc., of elevators and conveyers, as is often the case.

The absence of stretch is the result of a strictly individual and scientific method of stretching the belting during the course of construction.

The special impregnation mixture used makes the duck absolutely waterproof and preserves the life of the belting, which will never dry out but will always remain pliable, strong and free from cracks.

With the great advantages gained by the features mentioned, both Victory and Ampere are lifted out of the ordinary class of this kind of belting and then present points of long life, efficiency and economy that are easily appreciated and recognized by the purchaser who wants the best of the kind.

Both grades are made in many commercial plies, widths and lengths. The company makes a specialty of wide and heavy belts for long conveyer work, elevators, etc., and is prepared to handle promptly all orders. Full information will be cheerfully given upon request and samples and prices sent to those interested.

NEW INCORPORATIONS.

Victoria, B.C.—Adkison & Dill, $150,000 (builders).

South Wellington, B.C.—Wellesley Lumber Co., $32,000.

South Vancouver, B.C.—Cement Products Co., $10,000.

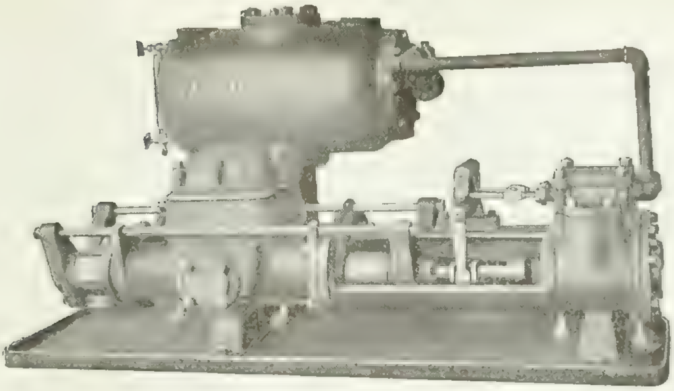
Girard. Lubricants, $200,000. C. Arnold, Westmount; T. Cozzolino, Sydney; G. A. Snider, Montreal. Newfoundland Slate Quarries, $500,000. H. J. Elliott, L. A. David, E. C. Baker. Canadian Incinerating Co., $100,000. Hon. F. E. Gilman, Westmount; P. R. Schravesande, L. H. Boyd. Canadian Filter Faucet Co., $250,000. J. R. Middlemiss, New York; W. J. Poupore, Sir E. R. Murray. Hadrian Flooring Company of Canada, $20,000. F. G. Bush, G. R. Drennan, M. J. O'Brien.



This Feed Pump and Receiver Is More Reliable Than a Steam Trap

It can handle sudden rushes of water better. By the use of this Pump the annoyances experienced with steam traps, tanks and similar devices are entirely eliminated.

This is a simple and effective combination of our duplex steam pump attached to a receiving tank, which receives the water of condensation and the pump automatically returns it to the boiler at the highest possible temperature.

It is especially useful for returning water of condensation from steam heating coils, drying cylinders, evaporating effects or in any place where it is desirable to return such condensation to the boiler at as high a temperature as possible.

The tanks used with our pumps and receivers are made strong enough to stand a pressure of 100 lbs. per square inch.

The capacity of the Fairbanks-Morse Duplex Ram Pattern Pump and Receiver shown above is 50 gallons per minute. Full details furnished upon request.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

18093—November 21—Authorizing C.P.R. to construct spur for the Brick & Supplies, Ltd., Sec. 20, Tp. 25, R. 3, W. 5 M., at Glenbow, Alta.

18094—November 21—Authorizing C.N.R. to construct spurs in city of Regina, Saskatchewan.

18095—November 21—Authorizing C.N.O.R. to construct across Sanguinet St., Montreal, Que., by means of overhead structure.

18096—November 20—Authorizing C.N.O.R. to construct across G.T.R., at Stoney Creek, Tp. Saltfleet, Co. Wentworth, Ont.

18097—November 19—Establishing the collection and delivery limits of the Dominion Express Co., in town of Macleod, Alta.

18098—November 20—Establishing the collection and delivery limits of the Dominion Express Company, in town of Windsor, N.S.

18099—November 20—Establishing the collection and delivery limits of the Dominion and Canadian Express Companies, in Sackville, N.B.

18100—November 20—Establishing the collection and delivery limits of the Dominion Express Co., and the Express Department of the Halifax and South-Western Ry. Co., in the city of Yarmouth, Nova Scotia.

18101—November 19—Recommending to the Governor-in-Council for sanction the Indenture of Conveyance, dated Oct. 3rd, 1912, between the Cap de la Madeleine Ry. Co., and C.P.R.

18102—November 19—Recommending to the Governor-in-Council for sanction the Indenture of Lease, dated Oct. 2nd, 1912, between the Kingston & Pembroke Ry. Co., and the C.P.R.

18103—November 18—Directing C.N.R. to construct a third-class station at Waldheim, Saskatchewan.

18104—November 22—Authorizing C.P.R. to construct additional track across two (2) highways on Swift Current Subdivision, Saskatchewan Division, mileage 52.34, to mileage 53.36.

18105—November 20—Restoring, subject to certain conditions, Order No. 16460, dated May 7th, 1912, authorizing C.P.R. to construct branch line at Merritt, B.C.; and rescinding Order No. 17549, dated September 21st, 1912.

18106—November 22—Authorizing the payment of $350 to the Vancouver, Westminster & Yukon Ry. Co., deposited to credit of the Board to defray expenses of constructing a spur.

18107—November 22—Disallowing Supplement No. 6 to Central Ontario Ry. Co.'s Special Joint Freight Tariff on Canned Goods, C.R.C. No. 298 (G.T.R.'s C.R.C. No. E. 1928); and restoring Tariff C.R.C. No. 298.

18108—November 18—Directing C.N.R. to appoint a caretaker to take care of station and freight shed at Beadle, Saskatchewan.

18109—November 22—Directing C.P.R. and C.N.R. to jointly publish and file a tariff of through rates on grain products from Grenfell, Sask., via Regina, to Glenavon at 18½c. per 100 lbs., and 19c. per 100 lbs., to Kipling.

18110—November 23—Authorizing G.T.R. to construct siding and spurs therefrom, for the Canadian Rumely Co., Ltd., Toronto, Ont.

18111—November 22—Approving proposed location C.P.R. station at Sumas Junction, B.C.

18112—November 11—Directing C.N.R. to immediately repair its fences along right-of-way between Dufresne and St. Ann, Manitoba.

18113—November 22—Directing G.T.R. to provide proper accommodation for live stock at Mildmay, Walkerton, Brussels, Waterloo, Chesley and Elora, Ontario.

18114—November 25—Authorizing T. H. & B. Ry. to construct spur in the Twp. of Saltfleet, Co. Wentworth, Ontario.

18115—November 25—Authorizing Algoma Central and Hudson Bay Ry. Co., to open for traffic its main line from mileage 93 to Hawk Lake Junction, mileage 164.5.

18116—November 25—Authorizing Algoma Eastern Railway Company to open for traffic main line from Crean Hill, mileage 22.7, to West River, mileage 60.76.

18117—November 25—Authorizing C.P.R. to open for freight traffic its Bassano to Irricana Branch between Bassano and Standard, a distance of 35.62 miles.

18118—November 25—Authorizing C.P.R. to open for traffic new second track of Chapleau Subdivision, from Cartier to Geneva, a distance of 3.6 miles.

18119—November 25—Authorizing C.P.R. to open for traffic its second track between White River & Tarpon, mileage 0 to mileage 3.5, Lake Superior Division.

18120—November 25—Amending Order No. 17715, dated October 10th, 1912, by substituting the words, "Franktown Road" for the words, "Main Street," in second line of recital to said Order.

18121—November 26—Suspending, for 60 days from December 1st, 1912, pending a hearing of application by Board, the Pere Marquette R.R. Co.'s Tariff C.R.C. No. 1539, and rate on coal from Detroit, Mich., to Windsor, Ont., as published in C.P.R. Supplement No. 9, to C.R.C. No. E. 1676.

18122—November [illegible]—Amending Order No. [illegible], dated April 26th, 1911, and [illegible], dated May 4th, 1911, authorizing C.N.R. to use certain lands of the C.P.R.

18123—November [illegible]—Establishing the collection and delivery limits of the Canadian & Dominion Express Companies, in town of Sussex, New Brunswick.

18124—November 11—Directing C.N.R. to file with the Board plan showing a [illegible] to be constructed at about mileage [illegible], Sec. 9, Tp. [illegible], R. [illegible], W. First Principal Meridian.

[illegible]—November [illegible]—Approving C.P.R. plan showing proposed reconstruction of [illegible] No. [illegible] of [illegible] Subdivision, Ontario Division.

18126—November 26—Authorizing C.P.R. to construct its Suffield to Kipp Branch across highways from mileage 0 to mileage 32.85; approving revised location of said Branch from mileages 0 to 21; and approving location of said Branch from mileage 21 to mileage 32.85, Alberta.

18127—November 25—Granting leave to C.P.R. to operate trains over diamond at the crossing of its railway with the Hull Electric Railway, until January 31st, 1913.

18128—November 26—Authorizing C.P.R. to construct two spurs, crossing the highways in Townsite of Bull River, B.C., and the Government Road in Lot 118.

18129—November 26—Authorizing C.P.R. to construct two spurs on the property of the Montreal Light, Heat and Power Company. on Lot Cadastral No. 159, Incorporated Village of Hochelaga, Que.

18130—November 26—Authorizing C.N.O.R. to construct across two highways in the District of Nipissing, Ontario.

18131—November 26—Authorizing G.T.P. Branch Lines Company to construct its Biggar-Calgary Branch across highway between Secs. 3 and 4, Tp. 31, Rge. 26, W. 3 M., mileage 85, Rural Municipality of Prairiedale No. 321, Dist. Saskatoon, Saskatchewan.

18132—November 25—Extending for a period of 30 days from the date of this Order, the time within which C.P.R. complete spur to connect present spur with present G.T.R. spur, which serves the Agricultural Implements Works of D. Maxwell & Sons, Lot 19, Con. 17, Tp. of Blanchard, Co. Perth, Ont.

18133—November 20—Authorizing C.N.R. to construct second track across Dawson Road in city of St. Boniface, Manitoba.

18134—November 28—Approving Marconi Wireless Telegraph Co.'s Tariffs of tolls C.R.C. Nos. 6 and 7, and cancelling C.R.C. No. 4.

18135—November 27—Directing that C.P.R. interswitching charges for any distance within, and including, 4 miles from Point-a-Carcy Wharf, not exceed 1c. per 100 lbs., minimum $3 per car, to or from private sidings, and 1½c. per 100 lbs., minimum $5 per car, to or from public team tracks, to become effective not later than December 9th, 1912.

18136—November 28—Extending until December 15th, 1912, the time within which the Dominion Atlantic Railway install electric bell at highway a short distance east of Berwich Station, N.S.

18137—November 28—Authorizing Algoma Eastern Railway to construct spur to Mond Nickel Mine, Lot 8, Con. 5, Tp. of Denison, Ont.

18138—November 27—Authorizing Michigan Central Railway to construct proposed bridge as part of No. 1 Government Drain, Tp. of Tilbury East, Ontario.

18139—November 28—Approving location C.N.O.R. station at Newburg, Ont.

18140—November 27—Authorizing Canadian Northern Montreal Tunnel & Terminal Company to construct across Vertu Road, between Lots 258 and 359, Parish of St. Laurent, Co. Jacques Cartier, Que.

18141—November 27—Authorizing C.N.R. to construct Morris-Portage Branch across Souris Branch of C.P.R. in S.W. ¼ Sec. 7, Tp. 9, R. 3, W.P.M.

18142—November 28—Approving revised location C.P.R. through Tps. 30-31, Rgs. 17-20, W. 4. M., Alberta, mileage 280.62 to mileage 303.03.

18143—November 28—Authorizing G.T.R. to construct siding for the Orillia Building and Realty Company, Limited, Orillia, Ontario.

18144—November 28—Approving proposed diversion of G.T.R. siding constructed to premises of Cleveland-Sarnia Saw Mills Company, Ltd., on Lots 1, 2, 3, and 4, Block S, and Lot 4, Block A, town of Sarnia, Ont.

18145—November 28—Authorizing C.L.O. & W. (C.P.R.) to construct bridge No. 33.2 over 4th Depot Lake, near Parham, Tp. Hinchinbrooke, Co. Frontenac, Ontario.

18146—November 27—Authorizing C.P.R. to open for traffic its second main line track from 1 Acadia, mileage 24.46, to St. Constant, mileage 35.9, Farnham Subdivision, Eastern Division; rescinding Order 17999, November 15th, 1912.

18147—November 28—Authorizing C.L.O. & W. (C.P.R.) to construct bridge No. 34.01 across 3rd Depot Lake, near Parham, Tp. Hinchinbrooke.

18148—November 28—Authorizing C.P.R. to construct spur for the Booth Lumber Company, Limited, situated on northerly side of right of way north of road allowance, between Cons. 1 & 2, Tp. of Etobicoke, Co. York, Ontario.

18149—November 26—Rescinding Order No. 18030, dated November 15th, 1912, in so far as it authorizes the crossing of Liberty Street, mileage 148.46, (by C.L.O. & W.) in town of Bowmanville.

18150—November 27—Authorizing C.P.R. to construct two spurs in the city of Sherbrooke, Que.

18151—November 28—Authorizing C.L.O. & W. to construct across highway between Lots 8 and 9, Con. 1, Tp. Brighton, Co. of Northumberland, Ont., at mileage 99.15.

18152—November 27—Authorizing C.P.R. to construct spur for the Monarch Lumber Co., Ltd., Saskatoon, Sask.

◆

RAILWAY ORDER AFFECTING CARGO AND TRAFFIC EMBARGO.

The Board of Railway Commissioners for Canada have recently issued the following order:—

Whenever a railway company subject to the jurisdiction of the Board, issues an embargo against any traffic, it shall, within forty-eight hours thereafter, file with the Board a copy of such embargo, with a statement of the conditions rendering such embargo necessary, the action required to remove such conditions, and the probable time such embargo will be continued. And when such embargo is withdrawn or cancelled, the company shall forthwith file with the Board a copy of such withdrawal or cancellation.

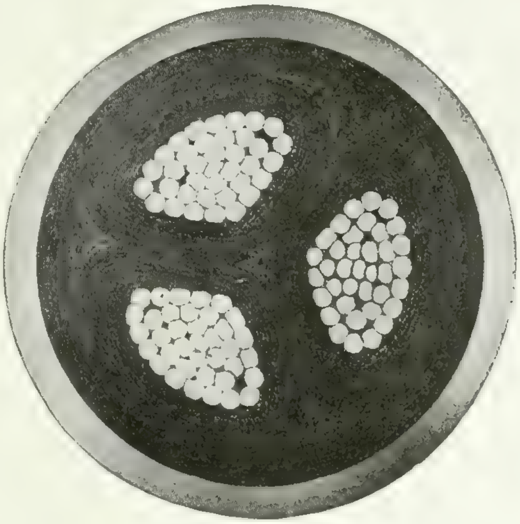
Power Cables

Manufactured by British Insulated & Helsby Cables, Limited

Paid-up Capital $8,500,000.00

HEAD OFFICE - PRESCOT, ENGLAND
Works at Prescot, Helsby and Liverpool

WORKING PRESSURE 13,200 VOLTS



300,000 CM. Three Conductor, Paper-insulated, Lead-covered Cable supplied to the Montreal Light, Heat & Power Company to the Specification of R. M. Wilson, Esq., M. I. E. E., Chief Engineer.

Sole Canadian Representatives:

TENDERS CALLED FOR

TENDERS FOR ANNUAL SUPPLIES, DEPARTMENT OF WORKS.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, Canada, up to noon on **Tuesday, December 10th, 1912,** for

Refined Asphalt,
Brass and Bronze Castings,
Brass Work for House Services,
Cast-iron Pipes,
Crushed Stone,
Cement,
Cedar Posts,
Field Tile,
Granite Boulders,
Hardware,
House Numbers,
Hydrants,
Treated Wood Blocks,
Iron Valve and Stop Cock Boxes,
Iron and Steel,
Lead Pipe,
Limestone Dust,
Lubricating Oils,
Lumber,
Paving Blocks,
Rubber Valves, etc.,
Sand and Gravel,
Special Castings,
Sewer Pipe,
Stop Valves,
Street Signs,
Sewer Brick.

Specification and tender form for any of the foregoing may be obtained upon application at the Head Office of the Department of Works, City Hall, Toronto.

Envelopes containing tenders must be plainly marked on the outside as to contents.

The usual conditions relating to tendering as prescribed by city by-law must be strictly complied with, or the tenders may be declared informal.

Tenderers shall submit with their tenders the names of two personal sureties, approved by the City Treasurer, or in lieu thereof, the bond of a guarantee company as aforesaid.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman Board of Control.

City Hall, Toronto, November 10th, 1912.

CITY OF KAMLOOPS, B.C.

STEAM POWER STATION EQUIPMENT.

EXTENSION OF TIME.

Tenders will be received up to noon Thursday, **December 19th, 1912,** for 1,000-h.p. Steam, Pumping and Electrical Equipment for the New Power Station for the City of Kamloops, B.C.

Plans and Specifications may be seen at the office of the City Clerk, and at the office of DuCane, Dutcher & Co., Consulting Engineers, Vancouver, B.C., or at the office of R. S. Lea, New Birks Building, Montreal.

Duplicate tenders must be addressed to the City Clerk, Kamloops, in a sealed envelope marked "Tender Power Station Equipment," and accompanied by a certified cheque for five per cent. of the amount of the tender.

Plans and Specifications may be obtained by making a deposit of $15, which will be returned on receipt of a bona-fide tender. The lowest or any tender not necessarily accepted.

J. J. CARMENT,
City Clerk.

Sealed tenders addressed to the undersigned, and endorsed "Tender for Addition and Alteration to the Central Post Office, Quebec, P.Q.," will be received at this office until 4.00 p.m., on **Monday, December 23rd, 1912,** for the work mentioned.

Plans, specification and form of contract can be seen and forms of tender obtained on application to Mr. A. R. Decary, Esq., District Engineer, Quebec, P.Q.; at the office of Mr. R. L. Deschamps, 103 St. Francois Xavier Street, Montreal, and at this Department.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to ten per cent. (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, December 2nd, 1912.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—30508.

CITY OF EDMONTON,

ENGINEERING DEPARTMENT,

1913.

Sealed tenders addressed to the undersigned and endorsed "Tenders for Paving, 1913," will be received at the office of the City Commissioners, Edmonton, Alberta, until 12 o'clock noon (12.00 N.) on December 10th, 1912, for approximately 400,000 square yards of Asphalt and Bitulithic Pavement.

Plans, specifications and all information may be obtained at the office of the City Engineer, or plans and specifications are on file at the office of The Canadian Engineer, 62 Church Street, Toronto, and the Contract Record, Toronto.

Companies wishing to tender on Asphaltic concrete pavement must submit their own specification, with tendered prices.

A deposit fee of fifteen ($15.00) dollars is required when plans and specifications are taken away. This fee will be refunded, provided that the plans and specifications are returned within 10 days after closing of tender.

An accepted cheque for the amount of five thousand ($5,000.00) dollars must accompany each bid.

The lowest or any tender not necessarily accepted.

CITY COMMISSIONERS.

Office of the City Commissioners,
Edmonton, Alberta, November 6th, 1912.

For further Tenders see page 76.

"STEELCRETE"

Expanded Metal Reinforcement

Twenty years ago the best—the best to-day. A reinforcement in readily handled sheets. Avoid labor costs—use the reinforcement suited to unskilled labor—STEELCRETE—it stays where put.

THE METHOD BY WHICH WE MANUFACTURE IS AN ABSOLUTE TEST OF THE STEEL.

Our automatic machines slit and open the meshes simultaneously from the cold sheet, thus increasing the elastic limit and the ultimate strength. The meshes are diamond shaped, the joints absolutely rigid. There are no corrugated or twisted strands—expanded metal lies flat.

NO STRAIGHTENING OUT ensues when load is applied to split the concrete before the reinforcement comes into tension. Once placed, disarrangement is impossible, as with rods. The required sectional area placed precisely as designed. Profit by others' experience. Use our "STEELCRETE."

Manufactured in Canada only by

TENDERS CALLED FOR

Sealed tenders addressed to the undersigned, and endorsed, "Tender for Machnery for 3½ Yard Dipper Dredge," will be received at this office until 4 p.m. on **Monday, December 30th, 1912,** for the construction of machinery for a 3½ Yard Dipper Dredge.

Plans, specification and form of contract can be seen and forms of tender obtained at this Department and at the offices of T. H. Schwitzer Esq., Mech. Superintendent, Birks Building, Ottawa, Ont.; A. E. Dubuc, Esq., District Engineer, Merchants' Bank Building, Montreal, Que., and J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works equal to ten per cent. (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.
Department of Public Works,
Ottawa, December 2nd, 1912.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—31360.

CITY OF REGINA.

TENDERS FOR POWER HOUSE, LAUNDRY AND REFRIGERATING PLANT AT REGINA GENERAL HOSPITAL.

Sealed tenders, endorsed "Tender for Construction of Power House, Laundry and Refrigerating Plant, Regina General Hospital," and addressed to the City Commissioners, Regina, will be received until 12 o'clock noon, Saturday, December 14, 1912.

Full particulars may be obtained upon application to Wenger & Cockburn, Room 208, Aldon Block, 12th Avenue, Regina.

Each tender must be accompanied by an accepted cheque for $2,500.00 made payable to the order of the city of Regina, which will be forfeited if the tenderer fails to execute the contract and bond when requested to do so.

The deposits of the unsuccessful tenderers will be returned when the contract is signed.

A deposit of $10.00 must be made with the application for the plans, as a guarantee of their return.

Proposals must be upon form of tender to be supplied upon application and must be in accordance with the provisions of the specifications.

Plans may be seen on file at the office of the Builders' Exchange, Winnipeg, and the Consulting Engineer, Regina.

The lowest or any tender not necessarily accepted.

L. A. THORNTON,
City Commissioner.

NEW YORK LEATHER BELTING COMPANY.

Notwithstanding that the price of leather is soaring to such an extent that its effect has been felt by leather belting manufacturers, whose business has been cut into by increased sales of textile belting, the New York Leather Belting Company has found it necessary to greatly increase its power plant and other parts of the factory owing to the recently former condition being inadequate to take care of increased business.

The power plant has been more than doubled, the heating system enlarged to heat increased space, and many other changes all through the large Brooklyn factory have been made and are now under construction.

When finally completed these will place the company in a better position to protect its friends in the way of deliveries, especially in very wide belts, a great number of which have been made and are now on order, contrary to the theory that such belts are being replaced by the use of direct connected installations.

The company's manufacturing facilities have not been equal to keeping up with the orders for Wetite, the waterproof leather belting, which is known the world over, and many thousands of feet of which have been sent to different parts of the United States and foreign countries.

It is but a very short time since the large additions to the lace leather tannery in Brooklyn were made to supply the demand for the company's lace leather products. The tannery is operated to its greatest capacity, such is the call for Victor brand of rawhide lace leather.

All of this goes to prove that the belting buyers of America readily recognize the economy of using high-grade quality leather belting distributed through jobbers only.

What would be your answer?

IF a layman asked you—an engineer or a contractor—what you thought of concrete roads, what would you tell him?

You're likely to be asked—if someone hasn't already put the query to you. "Good roads" is a subject of vital interest to Canada and Canadians just now.

You're used to questions. People have a habit of asking men in your business about everything from aeroplanes to filtration plants.

You can answer most of them off-hand; but have you taken time yet to thoroughly post yourself on this big question of the day—"Good Roads"?

We've saved you most of the trouble of doing so, by collecting and "boiling down" a great amount of information on highway construction and especially on concrete highway construction. This information is complete and definite. It is yours—free for the asking.

A LETTER requesting our "Good Roads" literature will put you in possession of facts that will enable you to answer any questions on the subject of "Good Roads."

CONDENSED ADVS.

Advertisements on this page are at the following rates per insertion: "Positions Wanted" advs., one cent per word; "Positions Vacant," "Agents or Agencies Wanted" advs., two cents per word; all other advertisements, three cents per word. The minimum charge per insertion is fifty cents.

POSITION WANTED as manager or superintendent of waterworks. Fifteen years' experience as manager, construction engineer and installing meter system with private company. Thoroughly familiar with all branches of waterworks business, especially in dealing with the public and employees. Open for engagement now. Address Box 298. Canadian Engineer, Toronto.

MECHANICAL ENGINEER, with large experience, is open for engagement. Box 294, Canadian Engineer, Toronto.

MECHANICAL ENGINEER seeks position. Large experience high-class machinery. Design, Manufacture, Estimating, Selling; held departmental charges with large firms. Good technical and practical experience. Box 278, Canadian Engineer, Toronto.

YOUNG MAN, GRADUATE OF A CIVIL ENGINEERING COLLEGE, experienced structural draughtsman, at present employed as structural draughtsman with a bridge concern near Montreal, is willing to do some work of engineering nature during his spare time. Write to Box 300, Canadian Engineer, Montreal.

MECHANICAL AND STRUCTURAL ENGINEER, with technical training, 18 (eighteen) years' experience in office and shop, wishes position as engineer with some company. Ready at short notice. Reply, with full particulars and salary offered, to Box 268, Canadian Engineer, Toronto.

HORNSBY'S CHEAP POWER.—$1.50 per h.p. per annum and upwards. Sixty to eighty b.h.p. in stock at Montreal; other sizes promptly. Address, Richard Hornsby & Sons, Limited, 212 McGill Street, Montreal, for Cheap Power Bulletin if you wish to generate your own power economically.

ONTARIO LAND SURVEYOR with 5 years' municipal and 4 years' railroad experience, at present in charge of railroad location party, wants permanent employment in former branch. Box 244, The Canadian Engineer, Toronto.

BLUE PRINT MACHINE—Buckeye electric, 42 inch by 5 ft.; two plates; used for 18 months; perfect condition. Full equipment of washing trays, etc., $200.00. First cost, $340.00. Box 296, Canadian Engineer, Toronto.

PRACTICAL ENGINEER and draughtsman, English, age 42, life experience in the design and manufacturing of locomotive and derrick cranes and other contractors' plant, seeks situation. Box 290, Canadian Engineer, Toronto.

WANTED AT ONCE, for about five weeks, by company at Niagara Falls, a first-class draughtsman who understands plant design. Travelling expenses will be paid to and from Niagara Falls. Apply stating qualifications. Salary $100 to $125 per month, depending on experience. Box 292, Canadian Engineer, Toronto.

CITY ENGINEER WANTED.

Applications will be received by the undersigned up to December 15th, 1912, for the position of City Engineer of the City of Peterborough, Ont. Applicants will state qualifications, experience and salary expected.

S. R. ARMSTRONG,
City Clerk.

November 19th, 1912.

TAKE NOTICE—That the undersigned are prepared to supply at a reasonable price Rolling Mills for I girders, described in Canadian Patent No. 103,260, or to grant anyone a license to have the same manufactured for him at a manufacturing establishment in the Dominion of Canada. They are also prepared to receive offers for the purchase of the patent or for licenses to manufacture under the same. Ridout & Maybee, 59 Yonge Street, Toronto, attorneys for Hugo Sack.

PATENT NOTICE.—Anyone desiring to obtain the invention covered by Canadian Patent No. 129,669, granted on December 6th, 1910, to C. Glaser and G. J. Muller, of Baltimore, Maryland, U.S.A., for Process of Refining salt, may do so upon application to the undersigned, who are prepared to supply all reasonable demands on the part of the public for the invention and from whom full information may be obtained. Fetherstonhaugh & Co., 53 Queen Street, Ottawa, Canada. Russel S. Smart, resident.

Patent Notice.—Notice is hereby given in regard to Canadian patents No. 102,830, Suspending and Hoisting Mechanism, granted January 1st, 1907, to O. Hetlesaeter, and No. 129,756, Steam Turbine, granted December 6th, 1910, to J. F. M. Patitz, that Allis-Chalmers-Bullock, Ltd., Montreal, is prepared to supply devices covered by these patents.

CRANE BRIDGE BARGAIN

Crane Bridge for sale at sacrifice, 5-ton capacity, 73 ft. 4 in. span, hand power operated, located at Sydney, Nova Scotia, used six (6) months, in A1 condition, cost $1,700.00. No reasonable offer refused. Send for sketch.

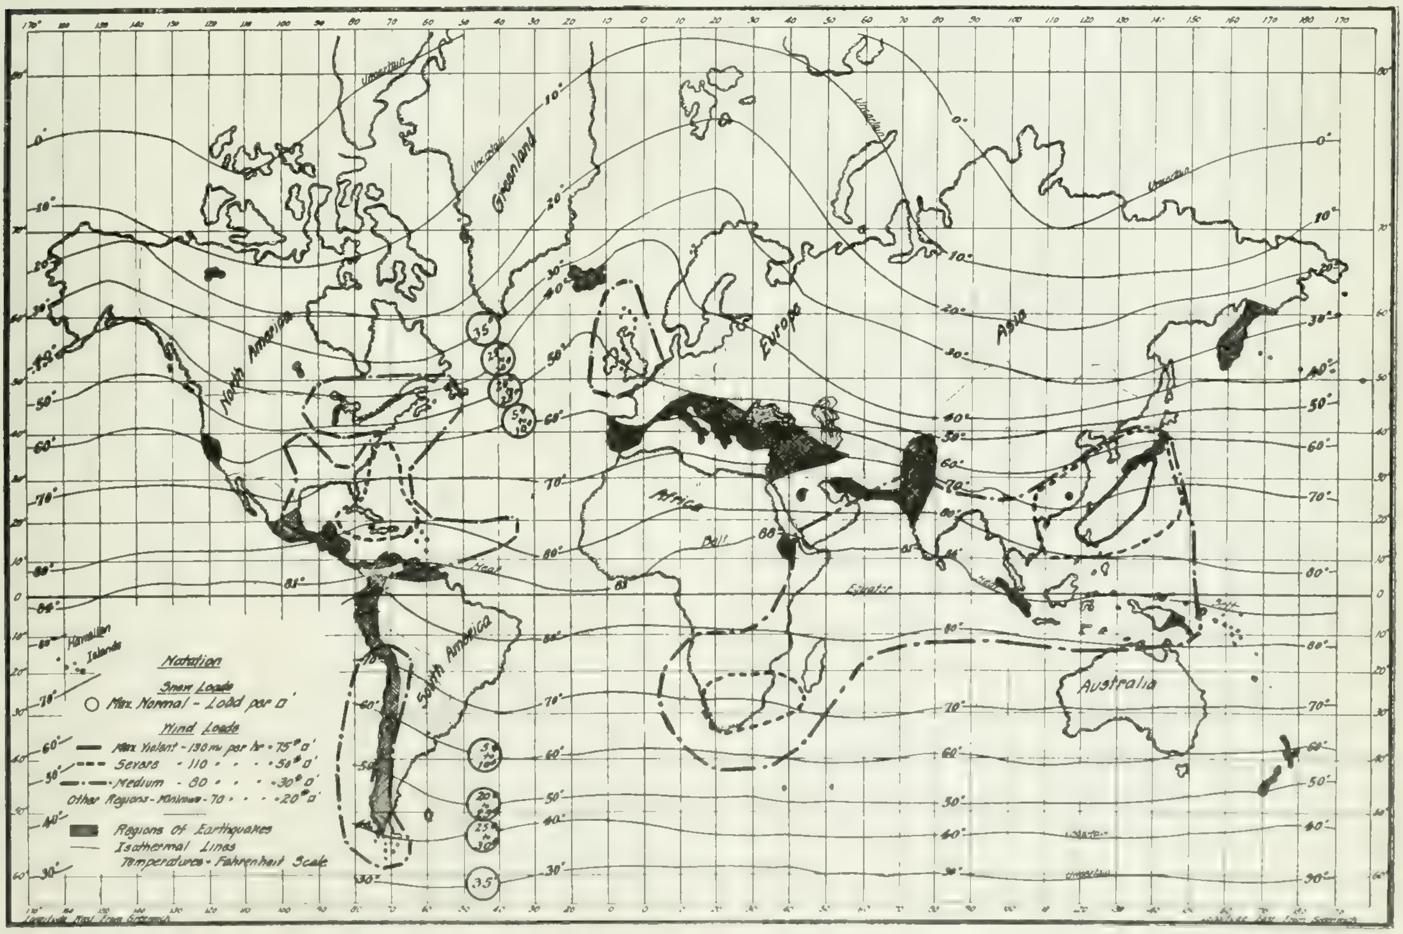
An Engineering Weekly

LOADING ASSUMPTIONS FOR STRUCTURAL DESIGN

By L. R. W. ALLISON.

Regional conditions of an extended period of time afford a basis for record which is vitally essential in computing loading assumptions for proposed structures. Variations in a specific locality covering many years would render a seasonable curve, if accurately plotted, comparatively uniform for the cycle average. Proper loadings for intelligent and comprehensive structural design, contingent with the elements, have been established for terms of latitude by practice.



North America
Greenland
Europe
Asia
Africa
South America
Australia
Hawaiian Islands
Notation
Snow Loads
○ Max. Normal - Load per □'
Wind Loads
Max Violent - 130 mi per hr - 75# □'
Severe - 110 - - - - 50# □'
Medium - 80 - - - - 30# □'
Other Regions - Minimum - 70 - - - - 20# □'
Regions Of Earthquakes
Isothermal Lines
Temperatures - Fahrenheit Scale
Longitude West From Greenwich

Such assumptions plotted upon regional lines are shown in the accompanying chart of the world. This offers in concise form, sufficiently accurate for all practical purposes, the fundamental considerations in design execution, especially for export work. The utility of the chart is evidenced for any section of the habitable world, and the method of composition permits of ready service. Additional loadings other than those dependent upon the elements are neglected, being, of course, features of construction that rest almost entirely upon the type of design and the particular purpose.

Snow Loads.—On the plotted temperature lines the normal horizontal snow load is given. This is maximum, and any reduction being proportional to the slope, the following formula is applicable:

Sn = normal snow load, pounds per sq. ft.

P = snow load for horizontal surface, pounds per sq. ft. (Obtained from chart).

a = angle of roof inclination with horizontal.

$$S_n = P\,(1 - \sin a). \qquad (1)$$

The curves obtained in Fig. 1, considering mean temperature from 30 to 60 degrees Fahrenheit, have been computed by this formula. This gives correct snow load assumptions for customary roof slopes from the horizontal to 60 degrees, or nearly 1 pitch, which is in excess of usual conditions. Any intermediate inclination is readily figured from the formula (1).

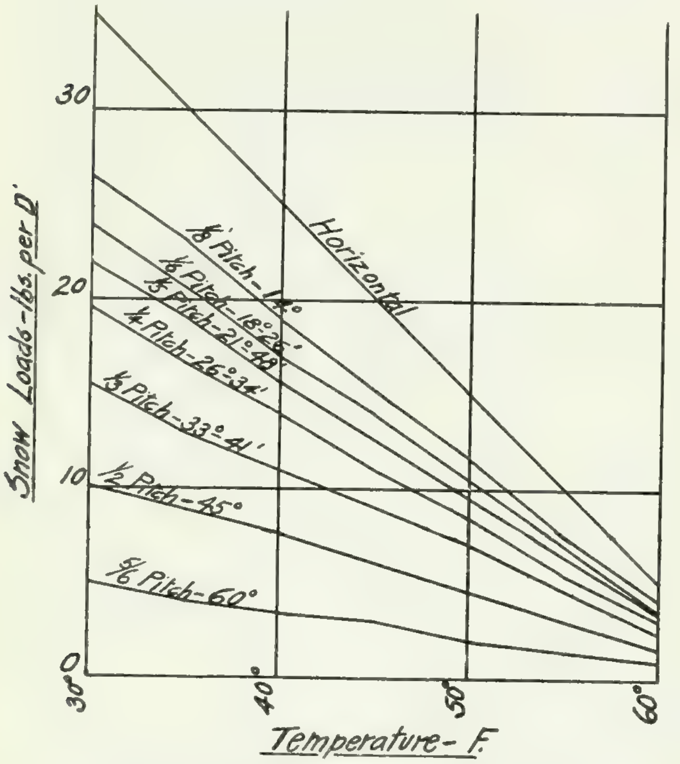


Fig. 1.—Snow Loads for Various Pitches.

Adjoining structures with roofs connected in series, as shown diagrammatically in Fig. 2, must be considered accordingly. Reduced loadings relative to pitch are computed for a, b, and c; full horizontal snow, as given on the map chart, is allowed for d, e, and f.

Correspondingly, when a high wind pressure is assumed the snow load should be reduced in proportion, in some cases practically neglected, as it is evident that such conditions would blow the snow from the roof.

Wind Loads.—Diverse conditions of winds and various allowances to be made for such are noted upon the chart. The pressure, dependent upon the velocity, is given as maximum. Such loadings, always considered as normal to the slope, are capable of reduction for customary roof pitches by using the following formula, and from which the curve (Fig. 3) is derived:

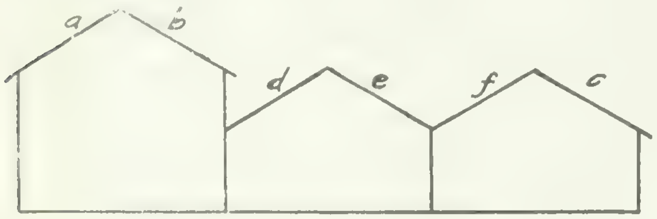

Fig. 2.

Wn = normal wind pressure, pounds per sq. ft.
Pl = maximum wind pressure on vertical surface, pounds per sq. ft. (Obtained from chart).
a = as in formula (1).

$$Wn = Pl\left(\frac{2a+5}{100}\right) \qquad (2)$$

For the various wind pressures given the formula (2) closely approximates the following:

$$\text{For 20 lbs. } Wn = \frac{4}{9}a$$

$$\text{For 30 lbs. } Wn = \frac{2}{3}a$$

$$\text{For 50 lbs. } Wn = \frac{9}{8}a$$

$$\text{For 75 lbs. } Wn = \frac{5}{3}a$$

These results are for "a" of 45 degrees or less; above this inclination the resulting normal and horizontal pressures are equal. The pressures given are in accord with modern practice, and for the United States and vicinity agree with tests made by the Signal Service Bureau.

Earthquake Regions.—The chart is serviceable in locating districts of seismal disturbances. As design in such localities embodies a thorough study of prevailing conditions, necessitating exceptional foundations and diagonal bracing for buildings in these regions, it is beyond the scope of intentions in presenting the map chart and explanation.

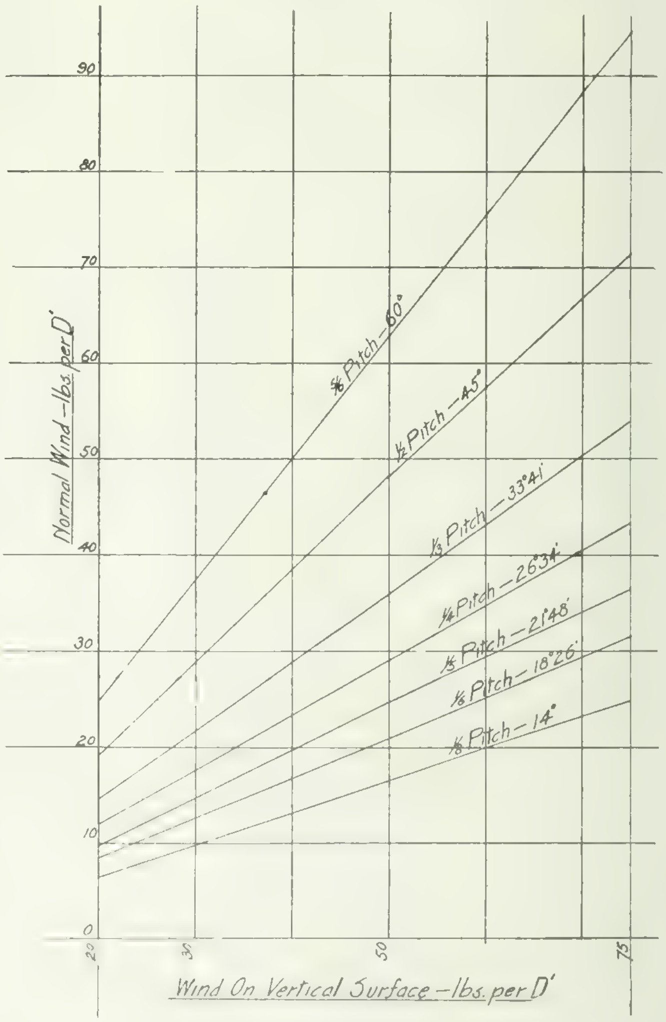

Fig. 3.—Wind Loads for Various Pitches.

The chart feature shown has been for some time employed in the engineering department of a large structural steel concern. The writer has embellished it where deemed essential, deriving the various curves shown from the formulas regularly used by this company.

THE PROTECTION OF THE FORESHORE AT DALLAS ROAD, VICTORIA, B.C.

The protection of the foreshore at Dallas Road, Victoria, B.C., has been the object of considerable work on the part of the Public Works Department of the province. Mr. G. M. Duncan, in a paper read before the Canadian Society of Civil Engineers, on November 7th, 1912, describes the work which has been done. The following abstracts are taken from the paper:

For several years the sea had been encroaching upon a part of this roadway, which runs along the coast overlooking the Strait of Fuca, with the consequence that the banks were gradually being eroded. In 1903 the city authorities commenced to build a low concrete wall to form some protection, and they continued building it in sections until it was about 1,500 feet in length in 1906. This wall, which had a height of 6 feet above high water, did not, however, prove of much service against the heavy seas which are prevalent during certain parts of the year. In 1910 the roadway was getting into a serious condition and the city authorities saw they would have to take immediate steps to form some permanent protection. A by-law was passed authorizing the expenditure of $75,000 which was augmented by the sum of $20,000 from the provincial government for the purpose of erecting more suitable protection works. The city authorities were in favor, and had the intention of building on top of the old wall, a proposal of which the public works engineer did not approve on account of the unstable condition of the foundations and general state of the wall.

After close investigation into the local conditions and a careful study of the various types of walls elsewhere constructed with similar objects, the conclusion was arrived at that protection could be most effectively and economically attained by a vertical wall carried down into solid ground below low water mark, except at its termination where it was anticipated the depth might be materially reduced. Trial sections of a solid and of a reinforced concrete wall were made and it was found that the cost of the former would considerably exceed that of the latter.

A comparison was then made between walls with counterforts 16 feet and 20 feet apart, respectively, and the balance in favor of economy proved to be for the latter. It was therefore decided that the wall should be vertical, carried up to the level of the roadway, of a reinforced concrete type without a base plate, with counterforts at 20 feet centres, and with a belt of granite in its face where the wash of the sea was greatest.

The calculations for the strains and areas of steel and concrete were then commenced and the following assumptions made:—

That all steel used would have an elastic limit of 32,000 lbs. per square inch.

That all rods should have a working stress of 12,000 lbs per square inch and be capable of being cold bent, 180 deg. flat on themselves.

These assumptions were subsequently required by specification.

The sketch shows typical sections of the wall and counterforts. The reinforcement in the wall consists of horizontal rods 1 foot apart commencing with ¾-inch diameter at 2 feet from top of wall and increasing in diameter with the depth of wall. These rods are link jointed and are kept in place between each counterfort by two face plates each ⅜ in. x 4 in. at 6 feet 8-inch centres. To the horizontal rods is wired expanded metal and No. 16, 1-inch mesh was at first used for this purpose but No. 10, 3-inch mesh was afterwards substituted on account of the former being found to be too light and the mesh too small.

The Dallas Road Sea Wall at Victoria, B.C.

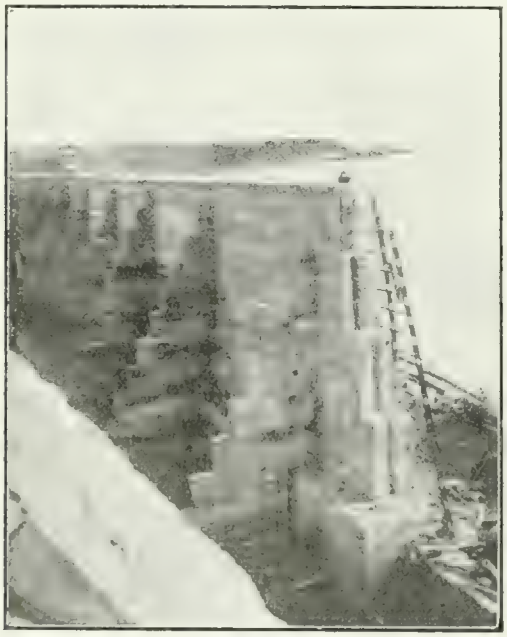
Fig. 3.
Section CD.

Plan.

The counterforts are reinforced in the same manner as the wall with horizontal tie rods hooked into face and back plates. It should be pointed out here that these tie rods and also the horizontal rods in the wall are subject to shearing stress at their connections with the face and back plates of the former and at the link joints of the latter, a point which is very easily overloaded. The back plates consist of 6-inch plates, ¼-inch and ½-inch riveted together.

At each counterfort the horizontal rods in the wall were at first placed between the face plate and the hooks of tie rods, but it was afterwards found that a more secure method was to place them at back of face plate and resting on tie rods of counterfort to which they were securely wired, and this method was adopted throughout the rest of the work. The bottom of all face plates are split and spread, and at the counterforts the face and back plates are held together by ⅝-inch bolts. The footings of the counterforts are reinforced with ¾-inch diameter rods at 4½-inch centres which are carried about 2 feet into wall and rods of same diameter at 7-inch centres and 7 feet long are placed between the bottom tie rods so as to thoroughly anchor the counterfort to footing.

To protect the wall from the wash of the sea and battering by drift logs, a belt of granite has been placed in the face of the wall as shown. Holes were drilled through the granite and ¾-inch diameter rods placed therein set with neat cement, thereby double clamping each stone. In the event of the cement mortar between the courses showing signs of disintegration the joints are to be raked out and caulked with lead wool. The lower part of the wall up to the shoulder, excluding the granite, is in the proportion of 1:3:6 concrete and all other concrete is in the proportion of 1:2:4. All concrete was of a "wet" mixture and the cement used was Portland. The exposed face of the concrete is of cement mortar in the proportion of 1 part Portland cement to 3 parts sand deposited at the same time as the concrete, and lifting plates were at first used to ensure the bond, but spading was afterwards adopted as being found more satisfactory.



View of Wall.

At the back of the wall a layer about 1 foot thick of broken rock is placed for facilitating drainage and a weeping drain of 3-inch drain tile placed in wall between each counterfort. The length of the wall is 1,680 feet, the greater part of which has an average height of 30 feet. It is finished on top with an iron pipe railing supported by reinforced concrete posts at 10 feet centres.

The work was done by contract and the total cost amounted to $119,020, divided up as follows: Wall, $112,130; convenience and steps to beach, $3,810; railing, $3,080.,

Work was commenced in January, 1911, and completed in February, 1912, but a great deal of delay occurred and time was wasted through disputes.

The plans were prepared in the Public Works Department by the author, acting under the instructions of Mr. Edward Mohun, M. Can. Soc. C.E., etc., who designed the work. Mr. A. E. Foreman, A. M. Can. Soc. C.E., was supervising engineer, and the contractor was the Pacific Coast Construction Company, Limited, Victoria.

PETROLEUM RESOURCES OF CANADA.

While the actual petroleum resources of Canada are comparatively small, nevertheless the potential resources are considerable.

In New Brunswick and Nova Scotia there are enormous deposits of oil shales which are valuable as a source of oil. On an average these shales will give a higher yield of crude oil than the oil shales worked so extensively in Scotland.

In the vicinity of Fort McMurray and Fort McKay on the Athabaska River, Alberta, there are enormous deposits of tar sands. The bitumen in the tar sand is the residue from evaporated petroleum and it has been estimated that there is 6½ cubic miles of solid bitumen in the tar sands exposed on this river.

Although enormous quantities of oil have evaporated from this district, nevertheless it is probable that accumulations of petroleum exist where the geological structure was such as to prevent its escape. This is also substantiated by the fact that natural gas occurs in quantity in districts where the tar sands are capped by overlying measures.

If large quantities of petroleum were discovered in Alberta, it would be a factor of great importance to the railway interests which operate in the Rocky Mountains and Jasper Parks and in forest areas in British Columbia and Alberta.

The Canadian Pacific Railway is now using oil-burning engines on its main line between Kamloops and Field in British Columbia. The Grand Trunk Pacific and some of the Canadian Pacific coast steamers also burn oil, and other boats are being changed from coal-burners to oil-burners. The oil is obtained from the California oil-fields. If supplies can be obtained at the prices now prevailing, its use will be very largely extended. Its cleanliness, the greatly decreased smoke, the decrease in the number of firemen required, the economy particularly in intermittent service, the increased efficiency—two boilers with oil, in steamship service, giving same steam as three with coal—and other considerations make it an almost ideal fuel.

◆

WESTERN WATER POWERS.

The Prairie Provinces' water powers upon which fairly definite information is available are mostly all confined to the southern portion of the provinces. This is a rather unfortunate coincidence and is likely to mislead the uninitiated regarding the total potentialities of these provinces, as the larger water-powers are situated in the north, on the Athabaska, Peace, Slave, Churchill, Nelson and other rivers. As even a preliminary survey of these rivers will be of great value, the Commission of Conservation has undertaken this work. During the last two summers, its Hydro-Electric Engineer, Mr. L. G. Denis, has been in the field making measurements of flow, height of falls, etc. Last year, the many rapids of the Athabaska River were investigated and the flow of the Peace and other rivers was measured. This year, the work included many long miles of travel, mostly by canoe, the western limit of the trip being the Peace River canyon in the north-eastern portion of British Columbia, while the northern limit was Fort Smith, on the Slave River. On the return trip the several rapids and falls in the Clearwater River and the upper waters of the Churchill were investigated. The general impression created by these large northern water-powers is that they will undoubtedly become of great value in connection with the wood-pulp industry. The raw material is close at hand, the only retarding factor, at present, being the lack of means of transportation and access. The details obtained by these investigations will be included in the Commission's forthcoming report on the "Water Powers of Western Canada."

MAINTENANCE AND REPAIR OF NEW YORK STATE HIGHWAYS IN 1911.

The following notes on the work done by the Bureau of Maintenance and Repair of the State Highway Commission of New York during the year ending December 31, 1911, have been taken from the last annual report of the State Commission of Highways:

Patrol System.—During the year there were 2,622 miles of improved state and country system of highways under the jurisdiction of the bureau. All of the minor repairs are cared for by the patrol system comprised of 594 patrolmen in charge of patrols of 5 miles average length. These patrolmen work under the supervision of highway inspectors in charge of sections of approximately 100 miles of roads each. These highway inspectors in charge of sections report in turn to superintendents of repairs in charge of the work in each division, the state having been subdivided into six divisions.

These patrolmen are required to furnish a horse and cart together with necessary small tools and to work upon his section between the hours of 8 a.m. and 5 p.m. In general the maintenance work done under the patrol system may be described as all work necessary to keep the surface of the paved roadway in as nearly perfect condition as possible, keeping the earth shoulders smooth and safe for traffic, the entire drainage system free from obstructions, noxious weeds and brush cut within the limits of the highway, small repairs to structures and guard-rail. In addition to these duties the patrolmen in numerous instances made surface applications of various dust layers upon the improved roads as granulated calcium chloride, glutrin and in some cases did surface oiling. Also they perform considerable work in unloading and delivering along the roads maintenance materials such as stone and oil. The number of miles to be patroled in 1912 is 3,151 and the number of patrolmen 698.

If the work of maintaining improved roadways is consistantly carried on the effective life of such roads will be greatly extended. It would appear as though it could be prolonged indefinitely, if year by year the material added to the road surface be equal or slightly in excess of the material which has been worn away during the same interval of time.

The experience during the years of 1909, 1910, 1911 has demonstrated that results of the patrol system has thoroughly justified its existence. The average cost for the entire state per mile for patrols for 1911 was $140.

For the season of 1912 it was proposed to subdivide the maintenance and repair work of the state into eight divisions instead of six, this change being necessary to give proper supervision to the rapidly increasing mileage of the improved state and county system of highways, also to have all the work in each county as far as possible under the direct supervision of one foreman or inspector, also to do most of the extensive surface piling and other repair work by contract. It is also proposed to do better and more permanent surface oiling treatment, substituting for the previous light oils applied cold with light cover costing about $500 per mile, a much heavier grade of bituminous oil applied hot covered with ¾-in. crushed stone and then rolled with steam roller costing about $1,000 per mile. This treatment in addition to being more durable avoids the criticism caused by the light cold application tending to soften up during continued wet weather, producing a sloppy condition which has been very much objected to by both vehicular and pedestrian traffic. While the first cost of this surface treatment is an increase over previous practice it is expected that in the long run it will result in a decrease of the total maintenance charge over a long period of time.

In 1911 there were resurfaced 48.23 miles at a total cost of $312,449, making the average cost per mile $6,509.

This resurfacing consisted of scarifying, placing stone and bituminous top dressing.

The total number of miles oiled in 1911 was 269. Total cost of oiling was $250,601; average cost per mile for oiling was $932.

The following is a summary of the result of the experiments:—

Oiled Surface Treatment Using Trinidad Liquid Asphalt "AA," Genesee County Road No. 586.—The summer season of 1911 was far advanced before the programme of surface oiling which had been laid out for the season's work was begun. It was determined to treat the surface of various roads with Trinidad Liquid Asphalt "AA" instead of the ordinary bituminous material C. O. and this was done upon Genesee county road No. 586 during September and October.

The usual methods for applying C. O. were followed, comprising sweeping the macadam clean of all mud, dust and loose material, followed by minor surface repairs to ruts, depressions, etc., with ¾-in. crushed limestone, the surface then being treated with Trinidad Liquid Asphalt "AA" which had been previously heated on account of the cold weather due to the lateness of the season so as to flow freely. Long stretches of one-half of the width of the road were treated and covered at a time so as to interfere with traffic as little as possible. The material used for covering the oil was rescreened or dustless limestone screenings. The oil was applied at the average rate of ⅓ gal. per square yard surface and the completed cost of the treatment, including all material and labor was $0.07½ per square yard. The oil cost in tank cars f.o.b. siding at delivery points $0.06¾ per gallon average. The stone for cover cost f.o.b. siding at delivery points $0.975 per net ton average. The total quantities of materials used were 988 net tons stone and 16,030 gals. oil. The width of the treated surface was 16 ft. and the length was approximately 5.2 miles. At the close of the year this surface was in excellent condition, there being no apparent tendency to mush up and become sloppy due to softening under continued wet weather. No roller was used during the prosecution of this work and the results were very satisfactory. The work was carried on under the patrol system the supervision of the Bureau of Maintenance.

Experimental Pavement Consisting of Limestone Top Course Macadam Bound with Glutrin.—Hudson Avenue, Sec. 1, Road No. 15, was originally improved during 1900, its length being 3,326 ft., or 0.65 mile at an expense of $7,242.67, or at the rate of $11,370 per mile, the surface being 16 ft. wide, the foundation course being of crushed limestone 4 ins. thick and the top course crushed trap rock 2 ins. thick, all water bound. The traffic carried by this road is exceedingly heavy, heavy loaded horse-drawn trucks of market produce, and sand and gravel from local pits predominating. The resulting wear required extensive repairs from time to time.

The cost of maintenance previous to 1907 was $6,376.40; expenditure in 1907, $277.81; in 1909, $2.25; in 1910, $542.27; in 1911 previous to this work, $46.55, making a total cost per mile per year for maintenance, $1,045.

During 1910 and 1911 the road was in a bad condition, depressions and ruts through the entire length of the roadway. This having been brought to the attention of the department during the latter part of September, 1911, it was decided to resurface the road with limestone bound with limestone dust and glutrin in solution, the general plan proposed being to fill up the depressions and ruts with coarse broken stone, restoring proper crown to the remaining old macadam and treating this as a foundation upon which to construct a macadam top course 3 ins. thick after rolling, this construction being adopted on account of amount of available funds preventing any more permanent construction. The work was carried on by County Superintendent J. Y. McClintock by the pay-roll system under the general supervision of the Maintenance and Repair Bureau.

The following points are taken from the specification for repair:

The upper course is to be composed of No. 3 limestone of an average thickness of 3 ins. After this is rolled and filled, spread over it ¾ lb. of pulverized feldspar per square yard of surface, and mix it in with the limestone by means of rakes. Roll with steam roller. Sprinkle with mixture composed of one part glutrin and three parts water, so as to get ⅜ gal. of glutrin into each square yard of the surface. Roll it until the stones are firm enough to walk over without any apparent movement.

For wearing course spread on limestone screenings. Put on enough to thoroughly fill the crevices between the stones. This will require thickness of about ¾ in. Now sprinkle with water and roll as usual until about one-half of the amount of water necessary has been applied. Then finish the sprinkling, and wet rolling with mixture of one part glutrin and three parts water. Now put sprinkling cart ahead of the roller and put on enough of the mixture to thoroughly flush the surface and wash the dust and small stones into the crevices. You cannot get the surface too wet, and you cannot roll too much. Keep on wetting and rolling until the surface puddles, which really means that it will not take in any more of the glutrin and water, the plan being to use about ¾ gal. of glutrin per square yard of completed road. Just before the surface dries, and this may be three or four days or a week later, the sprinkling cart should be filled with the mixture of one volume of glutrin to one of water, and the flow so regulated as to spread only 9 ft. wide. Sprinkle until ⅓ gal. of water or ⅔ gal. of mixture is applied to each square yard of the middle 9 ft. of the road.

This work was begun during the latter part of the month of September and progressed through October and November, when it was necessary to shut down for the season, due to the setting in of freezing weather. This necessitated building a portion of the road without glutrin in order to make it passable for the winter, with the idea of concluding the glutrin treatment in the spring.

The entire expense for this construction for the season's work, including all of the materials necessary to finish it up in the spring, is:

Use of steam roller	$ 392.23
Labor	873.12
Teaming	1,077.87
2,616 tons of stone	2,051.49
3,352 gals. of glutrin and crushed feldspar	403.58
Miscellaneous items	14.51
Total	$4,812.80

The number of square yards treated was 5,913, making an average expense of 81.4 cents per square yard of surface. It is fair to state that a portion of the labor, possibly one-quarter, should be charged to fixing the shoulders and ditches. A portion of this road, a few hundred feet upon which the glutrin was placed, was entirely constructed of No. 2 stone, and before winter set in, it showed signs of displacement because of being so small.

Glutrin was first used in Orange county in 1910 on roads Nos. 44, 93 and 160. The results were as follows:

On road No. 44, Goshen to Florida, the product worked especially well. About one mile of road on No. 44 is macadam. Before the application of glutrin this section of the road ravelled badly every year. The glutrin seemed to have a binding quality and the macadam section held tight the entire season of 1910. On the gravel section the product worked well as a dust layer. About the only fault one can find with it is that it is soluble in water and one or two days' rain causes it to move to the shoulders of the road. The results on road No. 93 were about the same as on road No. 44.

The department considered it satisfactory on roads Nos. 44 and 93 in 1910 and it was recommended for use on these roads for 1911. The residents seemed to like the glutrin and many citizens in the village of Florida ordered it in barrels for use in front of their dwellings.

On road No. 160 the results were not so good as on Nos 44 and 93.

The chief complaint from the public was that after rains it left the road in a soft and sticky condition. It is believed this was partly due to the poor material used in the construction of the road. The supervisor and several citizens requested that oil be used in the place of glutrin in 1911 and oil was recommended for No. 160 this year.

Glutrin was used again this year on roads Nos. 44 and 93 and is giving such good results that the first deputy in charge of maintenance has recommended its use next year. The people along the roads seem to be particularly well satisfied with it this season and many requested its use in 1912.

Details of various experimental pavements in Munroe county, among which are the Rocmac on road No. 83, the Mixing Method Asphalt, road No. 94, the Kentucky Rock Asphalt also Amiesite on road No. 5, and the Cube pavement on road No. 6 were given in Engineering and Contracting of November 15, 1911. The conditions of these various surfaces one year later, after they have been under traffic for over one season, are thus described in the report for 1911:

At the close of the season 1911 the Rocmac pavement on road No. 83 in the town of Gates was in perfect condition. It has not shown any indication of either ravelling or rutting. It is only slightly dusty. Continued wet weather does not produce any mud upon the surface. The surface being quite gritty gives excellent footing for horses and also reduces the liability to skidding of pneumatic-tired vehicles. Maintenance expense practically nothing.

The Mixing Method, Asphalt, laid on road No. 94 at the close of the season of 1911, was in perfect condition, there being little indications of wear, the surface being very smooth. The maintenance cost on this section during the season having been nothing except for work smoothing up the earth shoulders.

The Kentucky Rock Asphalt on road No. 5 at the close of the season of 1911 was, where laid during warm weather, in good condition. However, the end which was laid during colder weather was in rather poor condition and had necessitated considerable repairs. It is evident from the results on this road that it is absolutely necessary that this material be laid during the hot summer months in order to secure good results. The good portion was generally smooth, showing, however, occasional bare spots where the stone appeared through the asphalt on the surface.

The Amiesite on road No. 5 was partially laid during both seasons, 1909 and 1910, and at the close of the season of 1911 was in good condition. However, during 1910 an effort was made over a portion of this surface to roll on a thin sealing coat of the treated screenings size material. Where this was done there was a tendency for this thin surfacing to break off. However, the pavement underneath this surfacing was found in excellent condition. It would appear that if any sealing coat is used in connection with this construction that it it should be rolled in together with the balance of the road instead of attempt being made to roll it on afterwards.

At the end of the season of 1911 the vitrified shale cubes laid in 1909 on Road No. 6 were still in good condition and showed but little effect from wear. The Portland cement concrete cubes made with soft gravel and laid the same year showed the effect of wear but still preserved a good smooth surface, except for a short stretch of 100 ft., where they had broken up. The reason for this break seemed to be a weakness of a foundation. The concrete cubes made in moulds very wet, which were laid in 1910, were found to be soft in the spring of 1911, and did not hold up under traffic. The frost seemed to have disintegrated them. Of the ash clay cubes laid in 1909 the soft burned ones did not stand up well, but the ones made with small amount of Jersey clay mixed with local clay and ashes were in good condition.

This piece of road was subjected to very hard usage by the frequent passage of heavy agricultural engines with very sharp lugs on the wheels. It seems to be demonstrated that with cubes made tough enough to stand the wear of traffic, this form of pavement will be cheap and satisfactory.

◆

THE EFFECT OF SAFE WATER SUPPLIES ON THE TYPHOID FEVER RATE.*

Disasters have occurred from drinking sewage polluted water due to three distinct reasons:

One.—Failure to purify a surface supply exposed to pollution.

Two.—Inefficiency of the purification.

Three.—Failure to supply the purified water to all parts of the city.

Failure to Purify.—The failure to purify a supply which is polluted or exposed to sewage pollution may usually be attributed to an undue confidence in a supply which is safe "most of the time." It is difficult to impress upon municipal officials, without a severe lesson, that to avoid disaster it is necessary to have a water supply safe 365 days in the year. It is difficult to make them see the necessity for purification when the supply may be safe 350 or 360 days in the year.

They consider the expense almost unjustifiable when the menace only exists for four or five days in the year. But when disaster occurs they are willing then to spend the money after the damage is done. Erie, Pa., extended their intake pipe far out into the lake. It was nearly five miles from the nearest source of pollution. During 1909 and 1910 there was no evidence of serious pollution, but in December, 1910, such pollution occurred, and was followed in the early months of 1911 by 135 deaths and over 1,300 cases of typhoid fever.

There is too much confidence placed in unfiltered surface supplies from inhabited watersheds. Even where there is alleged control of the watershed and ample storage, pollution may occur. In regard to unfiltered surface supplies the need of bacteriologic control is very evident. Dangerous pollution may be present only for a few days or for a few hours. This is most likely to be disastrous in time of drought or low water. At such times the diluting effect of the inflow and the purifying effect of storage are both reduced to the minimum. The bacterial count per cubic centimeter is valuable, but the quantitative estimation of B. coli is of far greater importance. A low count does not necessarily imply a safe water, but a low count coupled with absence of B. coli may be considered an index of safety.

The typhoid epidemic in Baltimore in 1910 was coincident with prolonged drought. The run-off from the watershed of the Gunpowder River was reduced to the minimum. The sewage pollution was thus concentrated, and gross pollution was evident upon bacteriological examination. B. coli was frequently found in 0.1 of a cubic centimeter, and sometimes in 0.01 cubic centimeter samples. When the run-off increased, affording greater dilution and increased storage, the water returned to normal and the typhoid fever dropped to a minimum.

In Europe, surface supplies are almost invariably filtered, and eventually such supplies in America will be treated or filtered.

The factors affecting sewage pollution of a water supply and which determine the relative danger to be anticipated for such pollution are:

The amount of polluting material, the presence of pathogenic organisms, the time of transit from the source of pollution to the waterworks intake, and the amount of water available for dilution.

Provided the amount of polluting material is considerable, that typhoid fever is prevalent on the watershed, and at the time of transit is within the bounds of time deemed necessary for the natural death of bacteria, pollution of the intake will take place. The last factor, the amount of dilution, will determine the intensity of the pollution. If the polluting material is great in amount, and if a swift current cuts down the time of transit, prevents sedimentation and retards dilution, then gross pollution results.

With a dilute pollution one need not expect a great explosive outbreak, but many cases of typhoid may result, especially following floods and rains. Often in the absence of explosive outbreaks in the winter or spring months it will be demonstratable that too many deaths from typhoid fever occur in the first half of the year. On the other hand, it is reasonable to suppose that the dilute infection may be responsible for many scattered cases which can not be traced to water.

These cases may not appear in sufficient numbers in any particular month to be remarkable or they may be obscured by occurring in the months when typhoid fever is accepted as an inevitable visitation.

Water may be responsible for many cases of typhoid when it is impossible to prove the case against it. We are able to fix the guilt on the water supply only in massive outbreaks of explosive character, but smaller doses can be responsible for smaller outbreaks or many cases spaced over a long period without any hope of proving this causation.

It seems quite probable that a dilute pollution of a water supply with typhoid organisms may exert an influence indirectly through the agency of milk. The very few organisms in the water through multiplication in the milk may be enormously increased.

Inefficiency of the Purification.—There seems to be an impression that the installation of the filter plant means safe water. This is not necessarily true.

The filter plant must be properly constructed and intelligently and efficiently operated. I have seen filter plants that were structurally perfect, intricate mechanisms designed after plans by our best engineers, yet these plans are sometimes placed in the hands of an assassin, entirely innocent of knowledge of the proper bacteriologic control of his plant.

Poor filter efficiency is often responsible for disaster in the shape of typhoid outbreaks, and may be due to several causes. The slow sand type may give poor filter efficiency when sufficient extra units are lacking, necessitating excessive rates and placing of "green" filters in service. Excessive rates, too little coagulant, insufficient sedimentation capacity, and insufficient storage are common operating and structural faults of the mechanical type. Sometimes a properly constructed plant is struggling with a raw water which has a high bacterial content, and even with fair filter efficiency yields an unsafe effluent. Probably the greatest single cause of a poor effluent from filter plants is inefficient operation by unskilled men. It is absolutely essential for good results that bacteriologic examination, including B. coli estimation, be made at least once daily, and in slow sand plants from each unit separately.

---

*Abstract of address delivered by Dr. Allan J. McLaughlin, United States Public Health Service, Washington, D.C., at the Sixth Annual Meeting of the Association of Life Insurance Presidents in New York City, on December 5th, 1912.

The man in charge must be able to do this. In mechanical filter plants, or with hypochlorite plants, he must also have the necessary skill to adjust his chemicals with a nicety according to the changes in the raw water. With such a man in charge of a properly constructed plant a safe effluent is assured at all times. When struggling with a bad raw water, he will use hypochlorite as an adjuvant with good results. He will study the peculiarities and fluctuations of the constituents of the raw water and adjust his treatment accordingly.

In showing the relation between water and the prevalence of typhoid fever it is essential to have accurate vital statistics. Too often we find in making an investigation that no accurate statistics are available. Happily the registration area is growing larger each year, but the enormous territory still outside the pale, which furnishes no statistics, is a disgrace to our civilization and our much vaunted progressiveness.

The Federal Government can only request such statistics as a courtesy, but surely in this day and generation no authority should be necessary to compel the furnishing of statistics to the General Government for the general welfare.

Failure to Supply the Purified Water to All Parts of the City.—To secure the desired result, elimination of water-borne typhoid, it is essential to supply the safe water to all parts of the city. The high typhoid rate in Toledo, in spite of a safe public supply, was due to the fact that more than half the population depended upon shallow wells which were known to be contaminated in many instances. In Pittsburg during 1910 wards 1 to 20 were supplied with filtered water. The aggregate population of these 20 wards was 401,622. The typhoid-fever death rate per 100,000 in 1910 was 13.4. Wards 21 to 27 comprise the old city of Allegheny, and have a total population of 132,283. This section received unfiltered water. The typhoid-fever death rate per 100,000 in this section in 1910 was 46.9.

To summarize, the following facts are pertinent:

One.—In the prevention of typhoid fever there is a necessity for safe water supplies for 365 days in the year.

Two.—Unfiltered surface supplies may be exposed to a dangerous pollution for a few days or even for a few hours only.

Three.—Supplies derived by impounding surface waters, and which depend upon storage alone to nullify the pollution of an inhabited watershed may be very dangerous in periods of drought and low water. The proportion of pollution is relatively greater at such times and the time of storage is greatly reduced.

Four.—Purification, whether by storage, filtration, or chemical treatment, must be efficient at all times, and this cannot be assured without bacteriologic control.

Five.—It is essential that a daily quantitative estimation of B. coli be made, as a low bacterial count does not necessarily mean a safe water without absence of B Coli.

Six.—There is a necessity for close supervision of municipal plants by the State to correct structural and operative defects and insure a safe water at all times.

Seven.—Bacteriologic control and State supervision would insure cleaning when necessary, and should prevent the putting in service of slow sand filters before the "schmutzdecke" is ripe.

Eight.—In order to control typhoid fever and eliminate water-borne typhoid it is not sufficient alone to have a purification plant. In addition the purification must be efficient and the purified water must be available in all parts of the city.

It has been said that every death from typhoid fever was either a case of murder or suicide. An even stronger statement has been made that for every death from typhoid fever somebody should be hanged. These statements have a strong basis of truth, but exceed the truth somewhat. A more conservative statement, and one which is unassailable, is that every case of typhoid fever is due to somebody's ignorance or carelessness.

Now, in regard to carelessness or criminal negligence, the punishment should fit the crime, but for ignorance the remedy is not punishment but education.

It is precisely in this matter of education that this powerful and intelligent association can achieve the greatest good. The educational campaign must be directed against improper disposal of human excreta, impure milk supplies, flies, uncontrolled cases of typhoid, filthy personal habits of individuals, and, above all, against contaminated public water supplies. This paper is limited to water-borne typhoid, and therefore the other very important factors are not discussed. In the campaign for better water supplies we must direct our efforts toward securing the co-operation of the municipal authorities and the individual citizen.

Municipal authorities must be impressed that it is their plain duty to furnish a public water supply which is safe 365 days in the year and not on which is safe "most of the time"; that the absence of large explosive epidemics is not proof that the water supply is safe; that dangerous pollution due to a combination of weather and other conditions may occur only one day in the year, as at Erie, Pa., and that such disasters must be prevented; that a dilute pollution may be responsible for cases of typhoid fever scattered throughout the year, without giving an abnormally high typhoid rate; that a public water supply cannot be assumed to be safe, unless it is shown to be safe by a daily bacteriological examination.

In regard to the individual citizen, he must be awakened to the seriousness of the excessive typhoid fever rate in this country. In so far as water-borne typhoid is concerned the citizen should be taught that municipalities have an obligation to furnish a public water supply which is safe 365 days in the year, and that it is his inalienable right to demand and receive such a supply. The standard which should be expected in order to indicate safe water should be, less than 100 bacteria per cubic centimeter and an absence of the Colon Bacillus or other bacteria of sewage origin in one cubic centimeter samples.

COMPRESSED AIR STORAGE IN ROCK.

In a recent issue of the Engineering and Mining Journal Mr. Frank Richards, of the Ingersoll-Rand Company, 111 Broadway, New York, gives some interesting data regarding compressed air storage in rock. We herewith reproduce the article and illustrations.

One of the most familiar annoyances or inconveniences in the use of compressed air is insufficiency of storage capacity. In most of the employments of compressed air, especially in mining operations, the air is used intermittently and the rate of air consumption varies over a wide range. At the same time the usual air receiver is so small as to have little effect in maintaining constant pressure.

It has often been proposed and also many times attempted to use old and abandoned workings of mines for air-storage purposes, but in many cases complete failure has resulted on account of the impossibility of making the rock air-tight. It is, therefore, a pleasure to call attention to at least one instance where this scheme has worked successfully. The storage capacity in this case is a hundred times that of the largest commercial air receiver usually furnished.

Fig. 1 shows the essential features of a crosscut and drift on the 700-ft. level of the Centre Star mine of the Consolidated Mining & Smelting Company, of Canada, Limited, Rossland, B.C., which has been fitted up to serve as an underground receiver. In this case the rock was so close grained and free from fissures that the leakage was inappreciable. Fig. 2 is a plan of the workings appropriated for the receiver, the dam being placed as indicated. At this point the rock was notched out so as to give a bearing at least two feet wide all around to take the thrust caused by the air pressure, which aggregated about 450 tons. The dam was made of concrete eight feet thick, reinforced as seen in Fig. 1, by nine horizontal arched rows of 30-lb. rails. A manhole, 14 x 18 in., was run through the middle of the dam and secured by a cover on the inner face.

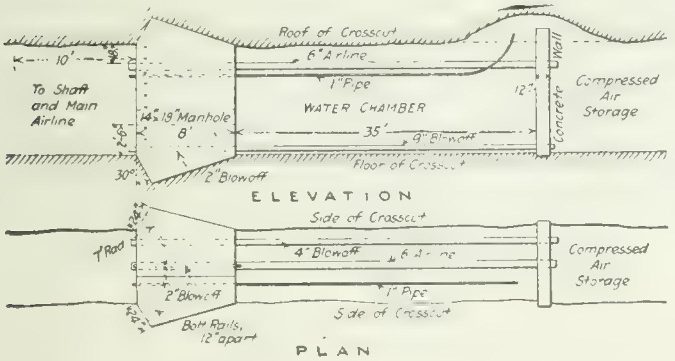

Fig. 1.

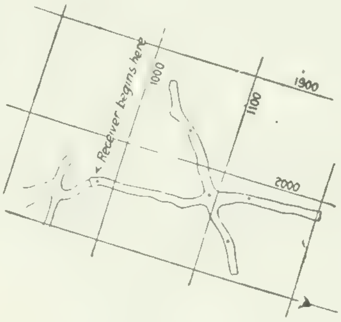

Fig. 2.

Compressed Air Storage in Abandoned Drift.

Inside the dam, with a space of 35 ft. between, was erected a concrete wall 12 in. thick to form a water chamber between it and the dam. It will be observed that this wall had to resist only the water pressure of four or five pounds at the most, the air pressure being effective equally on both sides, communication being free over the top of the wall.

The air communication between the main air line and the storage chamber was through the 6-in. pipe, this passing through the water chamber on the way. Any water which might accumulate in the bottom of the storage chamber could be drawn off through the 4-in. blow-off, while the 2-in. pipe would discharge the water from the water chamber when required. The function of the 1-in. pipe is not clear, but it could be used, like a try-cock on a steam boiler, to show whether or not the water was up to the turned-up head of the pipe.

How the water chamber was kept filled does not appear, but a pump must have been required for the purpose. It does not appear in fact how much the water scheme was used, Fig. 1 being from a blueprint made before the storage system was put into use. The air, so far as the storage function was concerned, was entirely independent of the water and we know that the storage is a permanent success. All necessary valves and gauges were, of course, provided outside to keep the engineers fully informed and in full control. For the information embodied in this article I am indebted to George A. Ohren, of the Canadian Ingersoll-Rand Company, Vancouver, British Columbia.

◆

LAYING NEW INTAKE PIPE AT MONTREAL.

The new intake for the water supply of the city of Montreal consists of double lines of 72-in. lock-bar steel pipe, laid on the bottom of the river from shore to the intake piers built in the St. Lawrence River just above the head of the Lachine Rapids where the water has a very swift current and is 32 ft. deep at high water. The work was described in a recent issue of the Engineering Record. Trenches from 7 to 10 ft. deep were excavated in the very hard, compact sand by a 2½-yd. dipper dredge moored by spuds and anchored by two 1-in. steel cables and one 1¼-in. cable.

The pipe, 9/16 in. thick, was manufactured in 28-ft. lengths by the Stewart & Lloyd Company, Glasgow, Scotland, and at the site was riveted up on shore to 140-ft. lengths and butt-strap joints. The ends were closed with temporary wooden bulkheads and the pipes were rolled from the wharf, dropping about 5 ft. into the water and were towed to position. They were lifted clear of the water by two floating derricks, the bulkheads removed, and were then lowered into the trench, where they were connected by divers who united them with gasketed flange joints. The joints were made up with bolts inserted by the divers who fitted the nuts to them and set ratchet wrenches on them operated by lines from the boats above.

Each of the double lines of pipe were connected to a 22 x 62-ft. concrete intake pier 30 ft. high which was built after the pipes were laid. Open caissons, with 12 x 12-in. timber walls, were floated to position, filled to a depth of 4 ft. with concrete, and sunk in pits dredged to solid rock. The caissons were pumped out and the concrete piers built in them in the usual way in forms, 8 ft. in diameter, with holes left opposite the ends of the intake pipes

Sections of 6-ft. steel pipe 12 ft. long were set in the pier openings, projecting into the interior walls, and the movable outer walls of the caissons were detached and floated away. Divers descended outside the intake piers and connected to the short pipes tackles which were operated by floating derricks to lift them and connect them up to the ends of the previously laid lock-bar pipes. The divers then sealed up the annular space around the pipes and both faces of the pier walls, after which the space around the pipe in the wall was grouted through holes left for that purpose in the concrete. The pipe in the trench was protected by a covering from 1 to 4 ft. deep, thus completing the work in about 4½ months with an average force of 50 men. Mr. George Janin is the city engineer, Mr. Thomas G. Lesage is the superintendent of waterworks and Laurin & Leitch, Montreal, were the contractors.

POWER SITUATION IN QUEBEC CITY

The large undertakings now under way, or in contemplation for Quebec city and surrounding district, have served to draw particular attention to the power situation at the ancient capital. At present, the Quebec Railway, Light, Heat and Power Company is obtaining about 5,000 horse-power at Montmorency and 1,500 horse-power from the Chaudiere. It had also been obtaining from 2,000 to 2,500 horse-power from the Jacques Cartier, but a short time ago the power plant of the Jacques Cartier Company was destroyed by fire and as yet the company has not proceeded with the reconstruction of the plant owing, undoubtedly, to arrangements that have been made for securing power elsewhere. This gives the Quebec Railway a combination of between 8,500 and 9,500 horse-power.

Recently, two new companies have come into the field, the Dorchester Electric, a small concern which, when connected, will have an output of about 1,500 horse-power, and the Stadacona Hydraulic Company, which will at the outset develop 10,000 horse-power from its powers at Seven Falls, and have so laid out their development that the output will be increased to 15,000 horse-power.

Owing to the large contract which the Stadacona Hydraulic has with the Quebec Railway, it was at first thought that there was some connection between the two companies. There is, however, no connection whatsoever, and while the Stadacona will sell a portion of its power to the Quebec Railway, it may indeed be a competitor against the Quebec Company for a portion of the balance of this power.

The development carried out by this new company brings about an entirely new condition in the city of Quebec and surroundings, as it will have an output in excess of all other companies combined and, in a measure, will be able to meet the requirements of a number of larger enterprises which will be established during the next few years. The Stadacona Hydraulic Company already has its output of 10,000 horse-power disposed of, 4,000 horse-power being under contract to the Quebec Railway, Light, Heat and Power, and 6,000 horse-power to the Bayliss Pulp and Paper Company. The Stadacona also has the right to enter the field in the city of Quebec, but the intention of the company at the present time is to be a wholesale concern only, turning over its output to large concerns, or to some of the existing power companies for distribution, thus occupying the same position as regards Quebec City as the Shawinigan Water and Power does in Montreal.

In view of the number of large undertakings now being provided for, it would seem as though the interests identified with the Stadacona Hydraulic had not carried out their plans for the new installation a moment too soon, and the new Harbor Commission of the city of Quebec is calling for tenders for the erection of a 2,000,000 bushel elevator which will take 3,000 horse-power to operate it. The Hon. Mr. Cochrane, Minister of Railways, has stated that the Grand Trunk Pacific intends to start in the spring of 1913 on the construction of a 5,000,000 bushel elevator which will require 8,000 horse-power. The Quebec Railway, Light, Heat and Power has closed a contract which comes into force in June, 1913, for 1,300 horse-power for the Quebec bridge, while the Transcontinental Railway shops now being erected are in the market at the present time for 3,000 horse-power.

The Stadacona Hydraulic Company will be supplying power about the middle of 1913. The large dam at Seven Falls, which is 70 feet high, has been completed, while the work has also been finished on the construction of the 8 feet penstock which extends a length of 3,200 feet. This leaves only the power-house to be constructed early next spring. The entire machinery for this plant has all been contracted for, assuring its delivery well within the time required. The power of the Stadacona Hydraulic has the greatest head of any in the world, amounting to 410 feet. The next in point of height is said to be located on the White River in California, which has a total head of 400 feet.

IRON ORE SUPPLY OF EMPIRE.

Some interesting evidence concerning the demand for and supply of iron ore was given before a meeting of the Dominion Royal Commission held on November 13th, by Mr. Wallace Thorneycroft.

It was stated that most of the ore imported into Great Britain was made into Bessemer hermatite pig-iron, which was used for steel making by the acid process. For that purpose the ore must contain very little phosphorus. Great Britain imported in the year 1909, 6,326,000 tons of iron ore, of which nearly 6,000,000 tons was Bessemer ore.

Nearly 5,000,000 tons of this Bessemer ore came from Spain, and the balance from Sweden, Norway, Greece, France, Algeria and Tunis. Except 62,000 tons from Newfoundland, no ore was imported during that period from the Dominions. Cumberland and North Lancashire supplied 1,558,000 tons of Bessemer ore. Therefore the Bessemer pig-iron industry depended upon foreign ore supplies.

The Wabana deposit in Newfoundland, from which the bulk of Canada's production of pig-iron was made, was said to contain over 3,000 million tons of ore. But as it contained .75 of phosphorus it was unsuitable for the manufacture of steel by the acid process. It was largely exported to Germany and Belgium, where steel was manufactured by the basic process, by which the phosphorus was extracted from the steel. Basic steel, it was stated, was not as reliable as steel manufactured by the acid process from Bessemer ore containing less than 0.5 of phosphorus. If the basic principle were adopted in this country there would be a greater demand for Newfoundland ore. The more rapid growth of the pig-iron industry in Germany and the United States was, it was said, entirely due to the invention of the basic process.

Except in Canada there was, so far as is known, no production of pig iron on a large scale in the Dominions. The governments of the Dominions, it was stated, might, with advantage, provide more money for the geological survey of the territory under their control. There could be no more profitable investment. They should publish the results of the surveys made as rapidly as possible, and communicate advance copies to the iron and steel associations of this country, or abstracts and references to such publications.

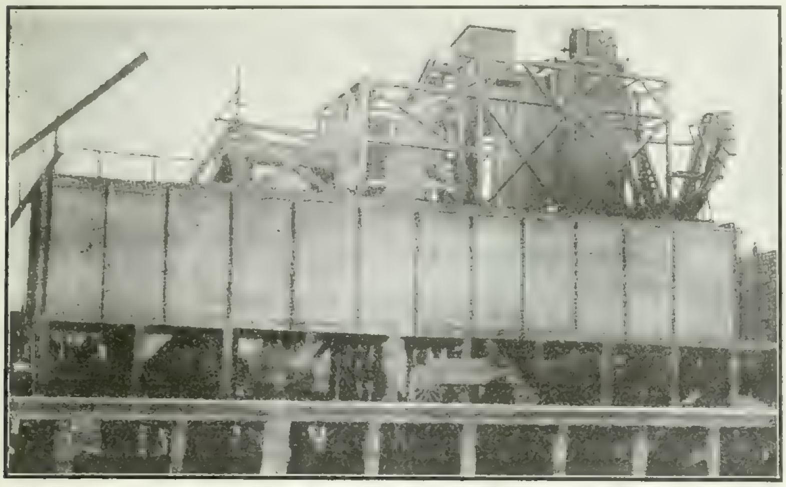
It was not suggested that the governments should undertake detailed prospecting work. The Geological Department of Canada was already very good, but with the vast area it had to cover, progress was necessarily slow.

The indication of large deposits, especially Bessemer ore, accessible for shipment anywhere in Eastern Canada or Newfoundland would promptly be investigated in detail by British makers of iron and steel and ample capital would soon be found if the deposits warranted development.

It would be right for the Dominion governments to encourage the report of iron ore. If the economic condition around the deposits were favorable, production of pig-iron and steel would naturally follow.

REPAIRING THE ASPINWALL FILTRATION PLANT.

As the only convenient source of water supply for the city of Pittsburg is the Allegheny River, the water must be thoroughly filtered before being delivered to the city mains. Accordingly, four years ago, the city spent over one million dollars in the construction of a filtration plant located at Aspinwall, Pennsylvania. This plant has been most effective in providing the city with safe and clean water. The entire plant covers 140 acres of ground and consists of a number of units called beds, covering ten acres each. Each bed in turn, comprises ten rooms, each covering one acre. These rooms are of concrete, having concrete floors and concrete roofs, these being supported by concrete columns, spaced 15 feet apart. The floor of each room is covered with several feet of sand and gravel, consisting of successive layers, varying from coarse gravel below to fine sand as the upper layer. Water, from the river, is pumped into these various rooms and allowed to slowly filter through the sand and is then pumped to the city's mains. The sand is frequently removed and washed by special machinery, which removes the sand from one room, delivers to a washer, and distributes over the floor of another room at the same time.



The Screening Plant of the John F. Casey Company.

Due to improper design and construction, considerable trouble was experienced with one of the beds of ten rooms from a seepage of water through the concrete floor. It was, therefore, necessary to remove all the sand and gravel from this bed, waterproof the floor, add several inches of concrete, wash and resize the gravel, and replace it over the floor.

The contract for this work, which involved the double handling of thousands of tons of gravel as well as the placing of a large amount of concrete, was given to the John F. Casey Company, which is one of the largest contracting concerns in Pittsburg. The method adopted by this company for handling the material, washing the gravel, and mixing and placing the concrete, allowed the work to be done in a remarkably short time and at a considerable economy.

The sand was siphoned direct from one room through the filtration plant sand washer into one of the repaired rooms by means of the sand scraping and spreading machines, which are part of the regular equipment of the plant. The sand, which could not be removed by the regular machine together with the gravel was loaded by hand into three-yard rocker bottom cars, which were hauled by gasoline locomotives to the washing and screening plant. In replacing this material in the repaired bins, it was withdrawn from the screening plant storage bins into industrial cars and hauled by electric locomotives over the top of the rooms. These cars dumped through manholes in the roof into the regular spreading cars, which deposited the material in even layers over the floor.

The washing and screening plant was located on the site of the filtration plant and was erected only as a temporary structure. The machinery equipment, however, although designed for this particular plant, was purchased with the idea of using it later on similar washing plants erected in connection with other contract work. On account of little available ground space the plant was made as compact as possible. The receiving hopper was located directly beside the bin structure and a belt and bucket elevator was placed to receive from the hopper and deliver to the screens above the bins. This elevator is equipped with 13 x 7 x 10-inch continuous buckets and the distance between head and tail pulleys is 50 feet. This elevator delivers into a chute feeding the first Gilbert screen from which it passes successively through three other screens and into a Stephens-Adamson automatic settling tank.

At this gravel had originally been washed and sized, the only object in rewashing was to remove the dust that had settled, and resizing was necessary as the various layers were necessarily confused in removing from the rooms. The city had very rigid specifications as to the maximum and minimum sizes in the various layers and the screens furnished were required to separate material according to these specifications. The size of the various bins was arranged according to the proportion of the different sizes which was definitely known.

Another part of the equipment, which assisted materially in reducing the labor cost and time on the job, was that for handling and mixing the concrete materials. A Haines concrete mixing plant was located on the site of the filtration plant, directly between the river and the railroad whereby the materials were brought to the plant. A derrick unloading rig and clamshell bucket was arranged to dig the gravel from barges and dump into a hopper above, from which it was drawn to the mixer as required. The cement was received in box cars in the usual manner and a belt conveyer was used for elevating the bags of cement to the top of the plant. The conveyer used for this was 24 inches wide by 86 feet centres using the unit ball bearing carriers.

This conveyer, as well as the complete screening plant, was designed by the Stephens-Adamson Manufacturing Company in their Pittsburg engineering office and this company also manufactured the entire machinery equipment for the plant.

◆

WELDING PIPE WITH THE OXY-ACETYLENE TORCH.

Welding with the oxy-Acetylene torch has been successfully accomplished in the large shops for several years, but the recent installation of an 8-inch high pressure gas line in San Francisco is unique in the adaption of this process to the welding of high pressure gas mains. This work was described by Leon B. Jones of the Pacific Gas and Electric Company, of San Francisco, in a recent number of the "American Gas Light Journal." The information here given is from Mr. Leon's description of the process and the cost of its application.

The recent installation of approximately 5,000 feet of 8-inch steel tubing in San Francisco, in which oxy-acetylene welding was used on every joint, was laid under the most difficult conditions. This afforded an excellent opportunity for practically testing the adaption of welding to high pressur gas mains. This line was laid in Geary Street, at the same time that the Municipal Railway was under construction; and this, necessarily, caused many obstructions and difficulties, but in every case, the oxy-acetylene welding proved itself equal to the occasion, and all difficulties were surmounted.

There are three separate methods in which pipe may be handled when welding with the oxy-acetylene torch. Bell holes may be dug as for any coupling, and the pipe welded in the ditch, or the pipe may be lowered into the ditch and turned while the welds are being made; thus, the welding of many of the joints is done on the top of the pipe, and the necessity for digging large bell holes at every joint is avoided.

The third method, which was found the most practicable, where conditions will allow, is to put short pieces of timber across the top of the ditch at intervals, rolling the pipe into places directly over the ditch. This method insures a good alinement of the joint, and requires the least labor. With it, two men can turn as much as 500 ft. of pipe, while the operator is welding the joints, and as a 500-ft. length is about as long as can be conveniently handled, it will thus only require a bell hole and a well in the ditch every 500 ft.

While it is possible to make a good weld without turning the pipe, a great deal more time and care are necessary than when the pipe is turned, and the welding is always done on top of the joint. In welding the under side of a joint in the ditch, it is not possible to pile up the metal, as it is when welding is done on top of the joint. A joint being welded in the ditch is also more often allowed to cool before the weld is completed, and this leaves a possibility of pinholes where the weld is commenced again.

To insure against the possibility of the mold not extending through the entire thickness of the pipe, the ends of the lengths to be welded were left about ⅛-in. apart, and the operator worked with a rod of 3/16-in. Norway iron in his left hand. This iron is melted into the joint to take care of the gap, and also to build up the metal around the joint. In this way the ends of the pipe are perfectly welded, and the metal at the joint is thicker than in the pipe; thus making the joint the strongest part of the line.

To prove this statement that the weld is as strong, if not stronger, than the rest of the pipe, sample welds were made, and the pipe was afterwards flattened and bent until it was broken. In every case the break occured back of the weld in the pipe and not across the joint.

A more practical test, which will appeal to gas men, was also made as follows: Two 40-ft. lengths were supported on timbers laid across the ditch, and the ends welded together. All the supports were then removed from under one of the lengths, and the entire weight of this 40-ft. length was suspended on the joint. The weld was in no way affected by this severe treatment.

After several hundred feet of pipe are welded into a section, the supports are removed, one at a time, and the pipe reeled into the ditch [illegible]. Careful handling is no longer necessary as a weld, if properly made, will stand the same treatment as the pipe, and any defect is better detected before the pipe is covered.

It may readily be seen that, when welding the pipe on top of the ditch, into sections several hundred feet long, it is possible to work several welding outfits at the same time, with the minimum of labor. If a little care is exercised in distributing the pipe along the ditch, two men can readily roll it into place, over the ditch, for welding. In many cases, after these sections were reeled into the ditch, the ends of the sections were several feet apart. To avoid using a short piece of pipe and making two welds, a block and tackle was used, and, with an automobile for motive power, these sections, in some cases 500 ft. long, were dragged several feet in the ditch to meet the end of the next section.

As the tubing which was used on this line was approximately 3/16-in. thick, and would not permit of threading, the question arose as to how valves or governors should be connected. This was solved in a very simple manner. A short piece of 8-in. standard pipe was threaded onto a standard flange. The standard pipe, which was 8-ins. inside diameter, was then slipped over the tubing, which was 8-ins. outside diameter. After the valve or governor was installed and the flanges bolted up, the end of the standard pipe was welded to the tubing. This installation, which represented about 180 joints, was welded throughout its entire length. At the end of each day's work the line was tested to 150 lbs. pressure and allowed to stand over night. As an extra precaution the joints were also gone over with soapsuds. After completion the entire line was tested to 150 lbs. pressure and the line stood at this pressure for three days without loss.

The oxy-acetylene torch develops a flame temperature which may conservatively be estimated at 6,000°F., and it may readily be seen that with this temperature concentrated in a small pencil flame under perfect control, all metals become amenable to the will of the operator. The torch used for oxy-acetylene welding is constructed upon the injector principle, in which the oxygen and acetylene are conveyed through separate tubes to within 1-in. of the point of combustion. The acetylene is usually conveyed direct from the generator, through hose connections to the torch, at a pressure between 3 and 5 lbs. per sq. in. The oxygen, stored in tanks, is used through a reducing valve and hose connections to the torch at between 15 and 20 lbs. per sq. in. On the handles of the torches are controlling valves whereby a nicer regulation is attained. For lighting the torch the acetylene is first turned on full and ignited. Oxygen is then added until the flame becomes a single cone. An excess of acetylene produces two cones and a white color, with an access of oxygen produces a violet tint.

The hourly consumption of the torch used for 8-in. steel tubing was 24 cu. ft. of acetylene and 30 cu. ft. of oxygen. Using acetylene direct from the generator, at a cost of 1 ct. per cu. ft., and oxygen from tanks at 6 cts. per cu. ft., at which price it is now available in San Francisco, the cost of operating the torch would be $2.04 per hour and, allowing 40 cts. per hour for the labor of an operator, the total cost of operation would be $2.44 per hour. As the average time necessary to weld a joint on top of the ditch, where the welding is done on top of the pipe, is 10 minutes, the cost of such welds would be slightly over 40 cts. per joint. The time necessary to weld a joint in the ditch, where the operator was forced to weld underneath the pipe, was 28 minutes per joint, making the cost of these joints $1.13 each; but if the pipe is welded into long sections on the ground it is only necessary to have a weld in the ditch to every 10 joints welded on the ground. This would make an average cost of 49 cts. per joint, which would be approximately 2 cts. per inch of circumference on steel tubing 3/16-in. thick, and from this can be estimated the cost of welding various sizes and thicknesses of pipe, as the time per weld, and consumption of oxygen and acetylene would increase in proportion to the size and weight of the pipe.

Railway Orders .... [illegible]

THE WATER POWERS OF CANADA.

Nearly a year has passed since the publication of "The Water Powers of Canada" by the Commission of Conservation. It was announced some time ago that another volume on "The Water Powers of Western Canada" was in process of compilation, and we understand that considerable work has already been done in the gathering of the necessary data.

We have had occasion at different times to refer to the volume already published; and, while a good deal of space has been given to it by the press in Canada, it is very doubtful whether the true value of the compilation is understood.

Probably the most valuable portion of "The Water Powers" is that dealing with the water powers of Ontario, and in particular that part which correlates the data respecting the legislation, public and private, connected with the great hydro-electric plants at Niagara Falls. This data is destined, in the future, to become more and more valuable as the work of the Hydro-Electric Commission of Ontario extends. Too much credit cannot be given to the author, Arthur V. White, C.E., for this section of the work. Perhaps no other man is as well qualified to handle it as he, and there can be only unqualified approval of the way the data has been compiled and presented. This section of the report has but to be read to appreciate the painstaking care and laborious research which he has, with an intimate knowledge of the local conditions, brought to bear on the work.

The importance of this work will be understood in the very near future. To-day at Niagara Falls 280,000 horse-power is being developed on the Canadian side by the hydro-electric companies. Of this amount 137,000 horse-power is being exported to the United States, or nearly one-half. At the present rate of increase in the use of electric power, due to the extension of the Hydro-Electric Commission system, it is a matter of a very few years until the demand will be greater than the available supply. The only complete record of agreements, franchises and legislation respecting these companies is that compiled by Mr. White, and to be found in "The Water Powers of Canada"; for that reason we feel sure it will be increasingly referred to as time goes on.

◆

TORONTO AND PURE WATER.

Toronto citizens are being asked to vote a large sum of money in January next for the duplicating of the filtration plant recently completed on the Island.

Ever since the inception of this plant there have been many, both through the press and otherwise, who have prophesied that the plant would not come up to the anticipations of its supporters.

This journal has always held that the choice of type of filter for Toronto was not based upon any reliable or ascertained data.

Ex-Controller Dr. Harrison, Dr. Sheard and others made a short visit to the States some few years ago, visited a few slow sand filter plants, came back and put a motion through Council that Mr. Allen Hazen, of New York (a slow sand filtration expert), be employed to make plans for such a filter for Toronto.

There were many, including this journal, who concluded that the proper course to have followed would have been to carry out a few simple experiments in order to ascertain first just what was the best type of filter to suit the local conditions. This was not done. No other system other than slow sand was considered. Advocates on municipal platforms were clear and impressive in practically guaranteeing that the system would remove at least 98 per cent. of the bacteria in the raw water, with the total elimination of all intestinal bacteria. Advocates appeared to have read Allen Hazen's book, entitled "Filtration of Public Water Supplies," a book which does not treat with or give examples of filtering similar water to that which forms Toronto's water supply. Advocates appeared not to have read or even heard of the high efficiencies which were being obtained by mechanical filters with similar waters to Toronto's water supply in England, the United States and elsewhere.

What is the result? Again history is repeating itself. Toronto is being asked to go blindly into spending a huge sum of money on a system of filtering its water which has not even under trial proved efficient. The question of the efficiency of the other method is not considered, apart from a general report by the engineer, who has practically completed his plans for a second slow sand plant, and who also was responsible for the first plant.

Apart from the question of this being business, is it engineering? Engineering is supposed to be a science built on the foundation of exact data. Its conclusions are supposed to be the natural outcome of experimental findings, either in the laboratory or in practice. Where are the experimental or any other data which should encourage the citizens of Toronto in voting a large sum of money for a duplication of a plant which has required a judiciary authority to stop up its one hundred and one leaks?

Manufacturer after manufacturer of mechanical plants have practically said: "We will put you in an experimental plant; if it does not work satisfactorily, then no pay." Every manufacturer of mechanical plants has been turned down. Why? Because the city's highly-paid advisor, prejudiced to a particular type, says it is the only type. Prejudiced because he has designed the first half, and any recommendation of another type for the second half would practically mean an admission that the first half was bad in type.

Commissioner Harris is not an engineer. Therein lies his strength as an arbitrator. He can afford to pass over the amenities and nice frills of engineering etiquette, which, unfortunately, do not always make for engineering efficiency. He can afford to choose the best, independent of the fact that Engineer Hazen was responsible for the first half, and just choose that the second half be based upon pure business and actual data. Let the one type be tried alongside the other, the results made apparent, and the best chosen. Thus only can the people of Toronto be sure that when voting for filtration in January next they are giving an intelligent vote for the proven system.

Toronto can afford to wait. With chlorine at the back of the water supply, risk of typhoid is eliminated. It is a question of clearing out turbidity either by mechanical or slow sand methods.

In the first instance, however, the excessive turbidity which interpenetrates the whole subject must be removed by evidence, so that the issue be clear and above board.

The subject is further referred to in detail on page [illegible] of this issue.

[The following letter Mr. T. Aird Murray, consulting engineer, who was one of the board of engineers that reported on the water supply of Toronto recently, has written in answer to certain questions we placed before him. The letter is self-explanatory.]—Editor.

(To the Editor of The Canadian Engineer).

Sir,—In reply to your enquiry re the recommendation in our report upon Toronto's waterworks, with reference to recommending mechanical filtration at Scarboro' and a duplication of the present plant on the Island. Of course I can only speak for myself. As far as my memory goes, the type or character of the duplication was not seriously considered as far as the Island plant was concerned. The question of type in connection with the Scarboro' scheme was thoroughly gone into, both with reference to probable efficiency and cost. Mr. Isham Randolph along with myself, went particularly into the question of cost, and we made it that a complete filter plant could be constructed at a cost a little over $10,000 per each 1,000,000 gallons of water treated.

Your point with reference to experimental data is good, and I certainly think the city would be in great error in spending any sum for absolute duplication of the present plant until it is made perfectly clear what the reasons are for the extraordinary variations in efficiency which have been peculiar to the Toronto plant ever since it has been operated. It also appears reasonable that the city should find out by experiment just what can be done by mechanical methods, especially as the area of land required by these latter types is very small compared to that required by slow sand. If mechanical filtration proved effectual, it would mean that an unlimited quantity of water could be treated on the Island, whereas, by slow sand methods, the quantity is, of course, limited to something like about two or three millions per acre. The successful treatment of Ontario Lake waters on the Island would probably justify the city in deferring the Scarboro' scheme to a much later date than at present appears.

I hold no brief for mechanical filtration as against slow sand. But it does appear now that the hypochlorite treatment is becoming universally an adjunct to either process, that the rapid methods may prove all that is required.

Further, there is no doubt but that mechanical methods have been greatly improved of late years, and that splendid results, comparable in every way with slow sand, are being obtained.

With reference to the question of operating cost, it may be taken that when the amount of coagulant required (if sulphate of alumina) is not more than one grain to the gallon that the total capitalized cost of mechanical filtration works out at a somewhat less figure than slow sand. For example, a ten million gallons per day capacity plant for each type would run about as follows:

Slow Sand Filtration.

Cost of installation, about	$200,000
Cost per annum for operating, sand washing and upkeep at $3.50 per 1,000,000 gallons per day capitalized at 5 per cent.	255,500
Total capitalized cost	$455,500

Mechanical Filtration.

Cost of installation	$100,000
Cost per annum of coagulants at 1 grain per gallon, labor, washing, etc., $4 per 1,000,000 gallons per day, capitalized at 5 per cent.	292,000
Total capitalized cost	$392,000

Balance in favor of mechanical filtration on above basis is, therefore, $63,500.

I may say it is very difficult to compare costs of either type, as one almost requires that both types be working alongside one another, dealing with the same class of water under the same conditions.

I think you are about the mark when you mention the requirement of half a grain to the gallon of coagulant for Toronto water. Of course, this would make the total capitalized cost even more favorable for mechanical. A half grain to the gallon would cost in Toronto about $1.25 per each 1,000,000 gallons of water treated.

Yours faithfully,
T. AIRD MURRAY.

TORONTO'S WATER FILTRATION PROJECT.

The problem of whether the slow sand filtration or rapid mechanical filtration provides the most efficient system for Toronto's water supply is before that city.

Under the advice of Mr. Allen Hazen, supported by Dr. Amyot, of the Provincial Board of Health, Toronto has completed a slow sand filter plant which evidently requires expansion. Further, under the advice of Mr. Allen Hazen and, we believe, again supported by the Provincial Board of Health, the city Works Commissioner advises the city to duplicate the slow sand filter plant already constructed.

Ald. Yeomans, of the Toronto city council, has taken up with no little enthusiasm the cause of the rapid mechanical system as against the proposed duplication of the present slow sand method.

Mr. Allen Hazen, as a sort of reply to Ald. Yeomans, again reiterates his conviction that conditions at Toronto are more favorable to the slow sand methods than to the rapid methods.

The Canadian Engineer has felt that it is due to its readers that some expression of opinion in this matter be made. We have looked into the matter for ourselves, with the result that we are forced to the conclusion that there is evidence that slow sand filtration is not suited to Toronto water supply, and that there is no evidence before the city that rapid mechanical filtration is unsuitable.

On page 13 of the Report of the Board of Commissioners, Toronto Water Works, 1912, the following paragraph occurs: "This board has concluded that a mechanical filtration plant will meet the requirements at Scarboro', and will cost less than a slow sand filtration plant similar to that on the Island." On page 15 the estimate of cost is given at $653,400 for a 60-million gallon per day plant. What we wish to know is: If such a plant is considered suitable at Scarboro', then why not suitable at the Island?

Capacity of Present Slow Sand Plant, Toronto Island.

Twelve filters, each having a filtering area of about four-fifths of an acre, with a rated capacity of 32,000,000 Imperial gallons per 24 hours, is a rate of 3.3 million gallons to the acre when all are in commission.

As one filter at least should be out of commission for cleaning and only eleven filters in use, the capacity is increased to 3.6 million gallons to the acre.

The maximum capacity is stated as being 48,000,000 gallons per 24 hours, or at the rate of 5 million gallons to the acre when twelve beds are in commission, or 5.4 million gallons to the acre when eleven beds are in operation.

Capacities Elsewhere.

	Average (acres.)	Average daily consumption.
United States	17.13	26.87
British Columbia	.82	1.80
Holland	22.75	31.48
Great Britain	161.80	362.73
Germany	106.22	117.13
Other European countries	34.74	88.84
Total	343.64	648.85

Average per acre 1.8 million gallons.

From this it would seem that the maximum capacity should not exceed 3.6 million gallons per acre by allowing double the capacity of the average rate as practised throughout the world.

Most of these results are with clear waters which have been impounded and settled before filtration, so that the clear water of Lake Ontario comes under the same classification.

Efficiency of Present Plant.

To analyze the efficiency of the present filtration plant let us review its results from June to October (without the use of chlorine), This should be a fair trial, as the filters started up in the early part of January last.

The following chart prepared by Alderman Yeomans is made up from bacteria counts supplied to him by the medical officer of health, and shows graphically the efficiencies.

In the first run we find an average bacterial efficiency of 86.1 per cent. in 26 days, while in the latter the actual efficiency for 10 days out of a 35-day period there is an average of 204.10 per cent. worse than the raw water.

All authorities are unanimous in their statements that well operated filters should give an efficiency of about 98 per cent. where the raw water count is not too low, but at all times should give continuity of results from day to day.

Clearly viewed in the light of these efficiencies, Toronto's plant is a failure. Why? Briefly the causes may be put down as follows:

(1) Type of filter unsuitable.
(2) Design of filter faulty.
(3) Faulty construction.
(4) Faulty operation.
(5) Too high rate relative to capacity.

Type of Filter.—Before considering the type of filter the quality of the raw water must be considered, and its relation to the principles of filtration.

Dr. Frankland, one of the greatest authorities on the action of filters, gives the results of the investigations of Piefke, the resident engineer at Berlin waterworks, in which he fully concurs, which determine that the slimy coating on the surface of the filter sand is the main cause of high efficiency rates.

"In a small experimental filter constructed by Piefke with **sterilized waterworks sand,** and set to work in the usual way, it was found that the power of retaining microbes was nil, that in fact more organisms were often found in the filtrate than in the unfiltered water, multiplication having taken place during passage through the filter. These experiments with sterilized sand **demonstrate that it is the slime deposit on the sand which constitutes the real filtering material in the waterworks filter.**"

Bearing this principle in mind, we must consider all forms of filtration. For large waterworks systems these can be resolved into:

Slow sand filters.
Gravity mechanical filters.
Pressure mechanical filters.

In the first the slime is formed naturally, while in the two latter it is formed artificially by the precipitation of alum in various forms with the action of the lime in the water.

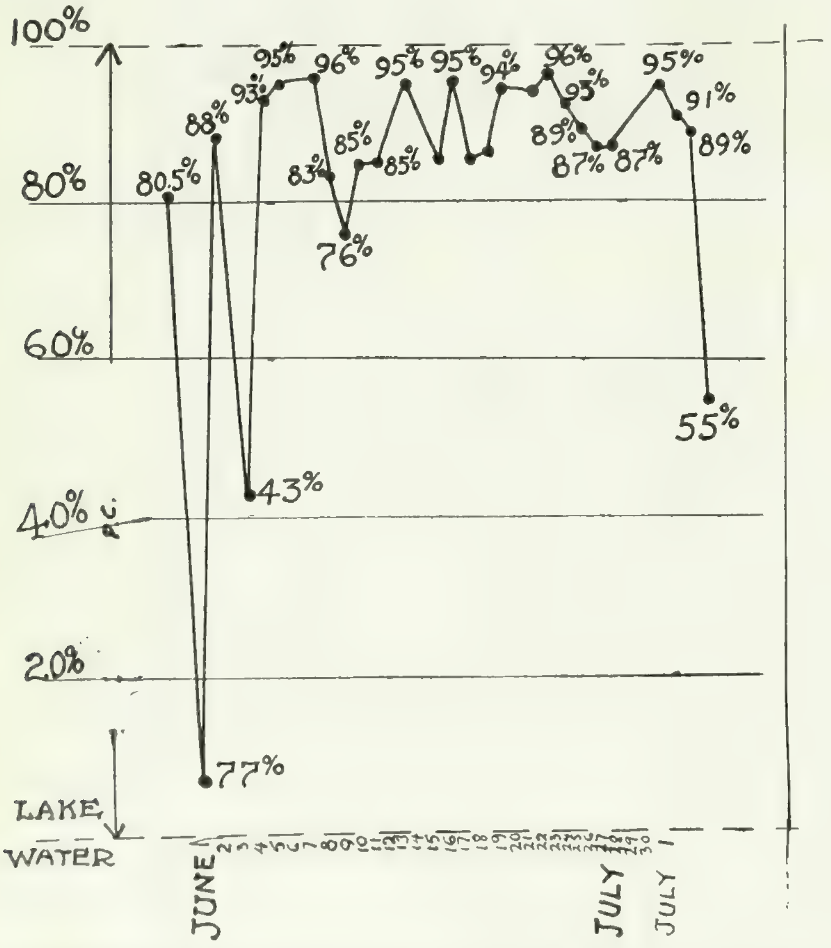
The first depends on the natural power of the water to form the film, while under the latter it is controlled.

If Lake Ontario water is so clear as to allow of the high rate of filtration which is being used, then it is too clear to form an efficient and strong film deposit, so that **probably the mechanical filter in this respect will be found more efficient.**

Of the two forms of mechanical filters the gravity filter is most successful in America, while in Britain the pressure filter holds first place. Both are found to give high percentages of efficiency, and to give them continuously.

Design of Filter Faulty.—In this respect an investigation was held, in which Judge Winchester presided. His summing up after all evidence was taken was that the design was all that could be desired, and this must be accepted with the mention that all filters should be designed so that they are absolutely watertight, according to the findings of the leading specialists and commissions. That there are leaks in Toronto's filtration plant has been established, and admitted by Engineer Hazen and his superintendent, Mr. Longley.

Faulty Construction.—In this respect Judge Winchester has decided that contractors have fulfilled the requirements of the specifications drawn up by Engineer Hazen, therefore, the question of leakages should rest with the question of design.



Graphic Diagram Showing Efficiency of the Toronto Slow Sand Filters from June 1st to July 5th, 1912.

Faulty Operation.—The filters having been operated to the satisfaction of Engineer Hazen's representative, under his supervision, any inefficiency due to their operation should rest with Mr. Hazen, who, according to the statements made from time to time in the daily press, authorized by him, is fully satisfied.

Too High Rate Being Used.—Commissioner Harris, Engineer Hazen, and Mr. Longley have repeatedly stated that the filters are being operated at too high a rate, so that they cannot be expected to give efficiency.

The responsibility for this rests with Mr. Hazen for designing and having constructed a filtration plant which will not give the efficiency required, even if such were done at the request of the council.

Surely an engineer should not hand over any plant to a municipality which he knows will not do the work required of it.

Present Position.—The present position, therefore, appears to be that either the design of the filter is faulty or its capacity is too small, both of which faults the designer has been paid a large sum of money to prevent. **In view of this, we do not think Mr. Hazen ought to be entrusted with the design of another filter until the efficiency of the present plant is placed beyond question, or mechanical filtration experimented with.**

It appears to us that what is required now for an extension of the present waterworks system is a filtration plant which we know will give efficient results. One that can be erected speedily to bring the present plant up to the capacity required, and one which will rectify the deficiency in filming due to the character of Lake Ontario water, by the addition of mechanical means under engineering control, not subject to the vagaries of the raw water.

From this review it appears that mechanical filters are worthy of independent investigation, and the reasons why they have not been so considered lead to the conclusion that Mr. Hazen's advice has been solely relied on.

Mechanical Filters Have Not Been Fully Considered.

Commissioner Harris is a good business man, but not an engineer, and as such has strictly relied on the advice of Mr. Hazen. Surely it is up to Commissioner Harris to have this advice from some other person than the engineer responsible for the first plant.

Mr. Hazen has been building slow sand filters for a great many years, and may be prejudiced in their favor, and may be loath to consider other methods which have arisen in more modern practice. He has reported that operating costs of mechanical filters are too high and they are not suitable for Lake Ontario waters.

A comparison of the two systems is therefore advisable, the principal points of which are as follows:

(1) Suitability.
(2) Efficiency.
(3) Operating costs.
(4) Methods of washing.
(5) Capital investment.
(6) Time for construction.
(7) Space required.
(8) Need for disinfectant.
(9) Taste, color, hardness.
(10) Operating supervision.
(11) Chances of pollution.

Suitability.—The question of suitability is chiefly determined by the raw water, and it is very doubtful if Lake Ontario water has the qualities necessary for the formation of the film which is the chief medium in obtaining efficiency, it would appear that an artificial means would remedy this defect to advantage, provided no trace of the reagent employed is left in the water after passing through the filter. Mechanical filter manufacturers have stated that they are prepared to give a guarantee that this can be effected.

Efficiency.—The efficiencies of mechanical filters (without chlorine) are invariably as high as need be desired, a few of them may be given as under:

United States, Atlanta	98.4%
England, Shrewsbury	98.8%

United States, Loraine	98 %
United States, Harrisburg	99.1
England, Buxton	99.6%
United States, Louisville	96.7%
England, Banbury	99.4

Numerous other results give in every case high efficiencies, as high as slow sand filters are showing in similar circumstances.

Operating Costs.—The chief cost of operation is the coagulant or reagent in the case of mechanical filters, and of cleaning in slow sand filters. For Lake Ontario waters an average of ½ grain of alum is required or 71 lbs. per million gallons treated, which at current market prices amounts to $1.06.

The average amount of sand to be washed on the American continent is 3.8 cubic yards per million gallons at 32 cents a cubic yard or $1.21 per million gallons. This does not include the cost of scraping, which might very well be balanced by the cost of washing sand by mechanical methods. It would seem, therefore, that there is a slight advantage on the side of mechanical filters in regard to operating cost.

Methods of Washing.—With slow sand filters the sand is scraped off by human agency, taken out and washed. With mechanical means all sand is washed mechanically in enclosed vessels which avoid any chance of contamination by those working on the plant.

Capital Investment.—Slow sand filters are a permanent investment and cannot be removed. The true mechanical filter is made up in units which can be moved to any desired location, according to the changes which make it necessary. In rapidly growing cities where the requirements and the policy of the future cannot be determined, this is a very desirable feature. The cost of the present Toronto plant is at the rate of $23,400 per million gallons treated, while rapid filtration is about $10,000 per million gallons. (See commissioners' report).

Time for Construction.—A duplication of the present slow sand filter will take about three years to complete. With mechanical filters the present shortage can be made good in eight months at the most, and other units can be added as they are required at short notice, so that shortages can be made up in a few months at most.

Space Required.—The space required for slow sand filters for a duplicate plant in Toronto will be above eleven acres. With purely mechanical filters less than one acre is required.

Need for Disinfectant.—With the present slow sand filtration plant it is absolutely necessary to have a disinfectant to prevent danger. With mechanical filters a purification of 97 per cent. can be obtained without the use of disinfectants, but a small amount would render the water practically sterile.

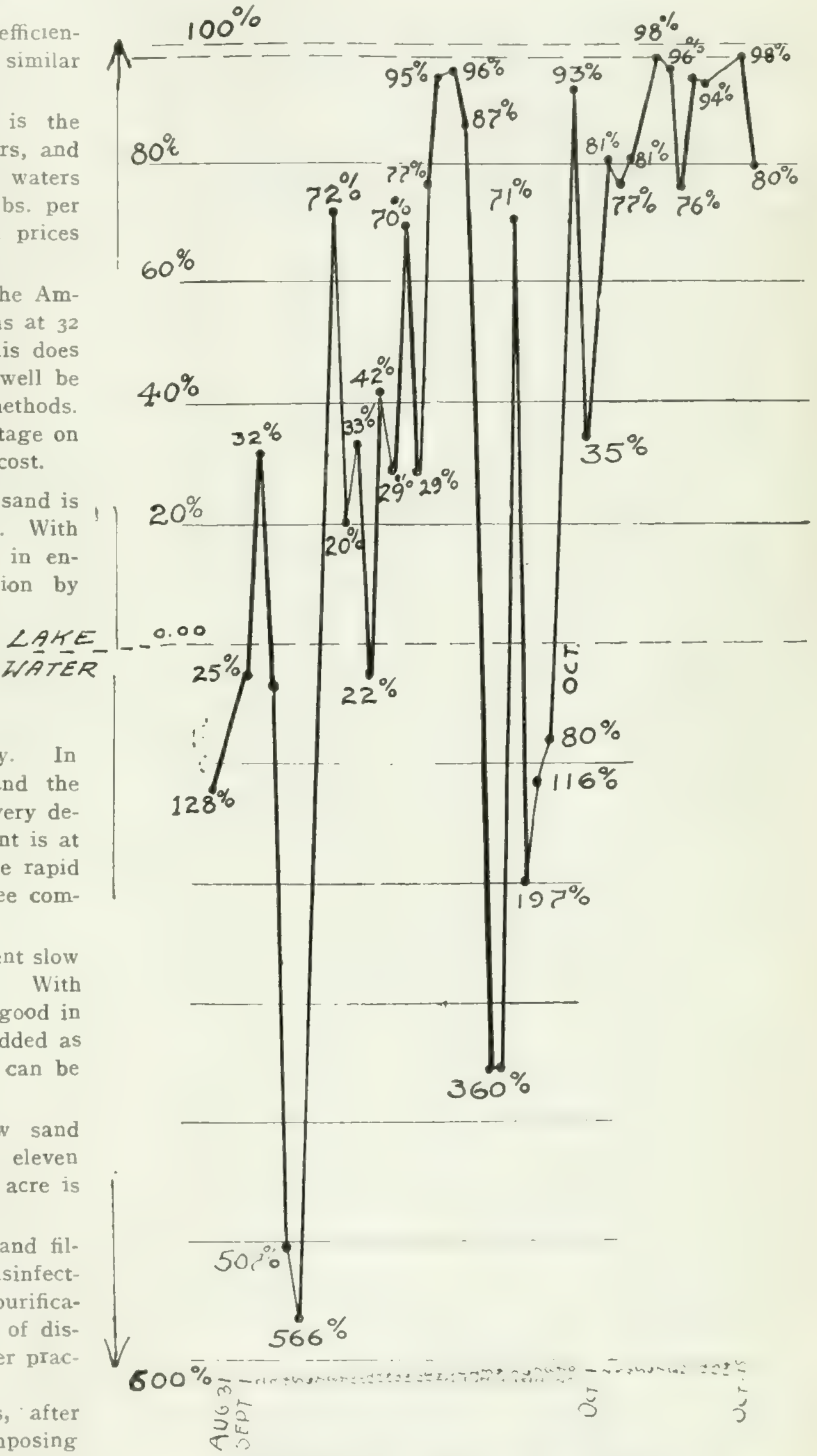
Taste, Color, Hardness.—With slow sand filters, after the filters have been idle there is a chance of decomposing vegetation giving a taste to the water. About 10 per cent. of color is removed, and there is no alteration to the hardness of the water.

With mechanical filters there is no taste, 90 per cent. of color being removed, while the water is increased about 1 degree in hardness.

Operating Supervision.—With slow sand filters skilled operators are required to see that the head is regulated to the flow, and to regulate supply to the filters to prevent their becoming inefficient by allowing too high a rate of filtration to pass.

With mechanical filters the engineers at the pumping station can secure the desired results.

Chance of Pollution.—Slow sand filters, being submerged, should there be any leakage from outside sources, there is serious danger which is not detected till after the water has been examined.



Efficiencies from August 31st to October 15th.

(Percentages for charts obtained from figures supplied by the Medical Officer of Health)

With mechanical filters every joint, pipe and filter is above ground, where any leak can be detected at once, and there is no chance of the outside water leaking in.

The former occupies a large area of foundation and runs considerable risk of settling, which makes the danger from cracking on insecure foundations very great, while the latter is not subject to this without immediate remedy.

There only remains, then, the fact of the pumping to the filters which would be greater in the case of mechanical filters, owing to their requiring a greater head of water to operate with, but this does not amount to more than fifty cents per million gallons, as per Mr. Hazen.

We have gone carefully into these facts and think that recommendation of the board of water experts for mechanical filters at Scarborough should be carefully considered in relation to the proposed extensions at the Island plant.

Alderman Yeomans has evidently undertaken a vast amount of research work in this question, and his case, as presented to the council, should have every consideration.

The urgency of the question, and the need for impartial consideration leads us to think that Commissioner Harris will do well to look further into the merits of mechanical treatment, and the employment of an expert who is well well versed in modern mechanical plants.

LETTERS TO THE EDITOR.

25-CYCLE CURRENT FOR LIGHTING.

Sir,—Your correspondent on this subject in last week's issue would seem to be puzzled as to the reasons for the choice of 25 cycles per second for current supplied by the Hydro-Electric System, and questions whether the effect of such lighting would be approved by an expert oculist. It is quite obvious that the technical exigencies governing the choice of this low periodicity did not include consideration for the eye sight of the lighting consumer. The advent of the small candle-power metal filament incandescent lamp has much accentuated the flickering effect of a low period current, owing to the extreme attenuation of the filament, as it is noticeable that with carbon filament lamps, possessing as they do a much slower temperature rise, this effect is much less noticeable. The same remarks apply to metal filament lamps of higher candle-power and consequently thicker filaments.

Carrying the matter further, anyone who has tried arc lighting on such a low periodicity as 25 cycles per second, knows that it is, for practical purposes, impossible.

HENRY COLES, E.E.

2 Toronto Street, Toronto, Nov. 30th, 1912.

CANADIAN ENGINEERS AND DRAUGHTSMEN.

Sir,—In reply to my friendly critic, Mr. Thomas, I would like to suggest to him that he has, to quite a large extent, proved my statements, although they were somewhat amazing to him.

First of all, I quite agree with him now, and if he will read my article again he will see that I recognized the fact at the time it was written that exceptions always occurred to the general principle I laid down with regard to the making of engineers from farmers.

These men were truly exceptions though, and would have made their mark probably in any branch of science and art. It was not, however, the exceptions that I referred to, but the great rank and file which is necessary to make up a mighty army.

I would ask Mr. Thomas, however, what is the natural tendency with, say, perhaps nineteen sons out of twenty? Is it not to follow in the steps of their fathers?

For myself, I am an exception to this, in a way, as my father was connected with the clerical staff of a railway system in the Old Country. Both my grandfathers, however, were workers in iron. Unfortunately, I cannot trace my pedigree back any farther than this, so that it is impossible for me to say how long the iron was in the blood. Now, I originally followed my father's footsteps when I started work, but found the work so uncongenial that at the end of about three years I gave it up and entered into my present profession. So, perhaps, in face of this evidence, it was a case of an exception in my father and not myself.

I am afraid I do not agree with the second paragraph of Mr. Thomas' letter.

Competition is keen everywhere, even in Canada, for the man who is looking up to the top of the tree. Also the statement that no one without shop experience could get a job as draughtsman in England is incorrect, as most of the offices I worked in it was the exception rather than the rule to find men with practical training.

Mr. Thomas must certainly have had rather an unlucky experience with his employers, I am afraid. I grant that the hours are longer, but I believe the province of Quebec stands alone in this from what I have heard.

Otherwise, I must confess that since I have been over here I have been treated more like a human being than I was in the Old Country, and as for the mutual trust and confidence, I think one has to merit that before you get it. It would not be reasonable for a boss, having sunk a good many thousands of dollars into his business, to let any man come along and do as he likes until he has satisfied himself his confidence is not misplaced.

The men in England who earn 35 shillings a week at mechanical engineering designing are the very sort of men who do not worry about theoretical considerations, and therefore are paid according to the service they give.

Mr. Thomas was certainly preparing for a storm, and I think every draughtsman would simply shout himself hoarse with opposition to his amazing statement.

Thanking Mr. Thomas for the opportunity he has given me of enlarging on this subject.

F. TISSINGTON.

Sherbrooke, Que., December 1st, 1912.

THE WORK OF RATS.

For many weeks the private telephone system installed in one of the largest and best-equipped printing offices in Canada has not been giving the service called for by the contract, and the electrical contractors, in accordance with the agreement, have searched for many days without even a clue. Outside of the fact that there was a short circuit on the line from the battery case, nothing could be secured, but first one instrument and then another would fail to respond or cross with another, or would work with complete satisfaction for a day or two, then drop off.

The cable was of the standard construction, wherein all the wires, insulated with cotton, wax-covered, are enclosed in a cotton covering, also waxed; this covering was, in the estimation of rodents, entirely suitable for use in home construction, and they removed the covering from every wire for a distance of about fourteen inches, and the bronze wire bears many indentations of their teeth. In their effort to remove the covering many of the wires were twisted around each other, and this, of course, was responsible for the ineffective operation of the system.

This illustration at once suggests the question, "Are many of the fires now laid to the cause of "defective electric lighting" due to these rodents removing the insulation from electric light wires in the same manner?"

Application will be made to the Dominion parliament for the incorporation of a company to carry on the business of fire insurance in all its branches, under the name of the Great West Fire Insurance Company. Messrs. Elwood, Embury, Scott and Graham, Regina, are solicitors for the applicants.

RECONSTRUCTION OF AN OLD RETORT HOUSE.*

By Mr. Howard E. Mann.

Prior to the year 1909 coal gas was manufactured in three retort houses at the Elm Station of the "Montreal Light, Heat and Power Company." These retort houses were referred to as No. 1, No. 2, and No. 3. No. 1 retort house was built in 1871. The building was of stone, 225 feet 6 inches long by 65 feet 7 inches wide, and 27 feet to eaves of roof. There were originally 19 direct fired benches containing seven 15 inches by 21 inches by 20 feet, through oval retorts. Recuperators were later added, and a pit excavated extending the full length of house on furnace side of benches. This pit was for clinkering purposes and the inspecting of recuperators. The recuperators were shallow, and would not be considered more than quarter-depth. The mouthpieces were old type with luted lids. Ascension pipes were 6 feet in diameter. The hydraulic mains were of cast-iron, with tar seal and overflow.

When first operated all the work of the recharging of coal and the discharging of coke was done by hand.

In 1895 "Bronder" charging and discharging machines were installed; also, an inclined cable system, with side-dumping cars, for the handling of coke from retorts to coke dump.

This installation was superseded in 1905 by DeBrouwer projector and ram. The house was also equipped with DeBrouwer coke conveyer, which extended the full length of retort house and up an incline to an outside radial coke conveyer. This radial coke conveyer was intended to cover a large area for stocking purposes. Owing, however, to design of tower, which supported far end of conveyer, it was impossible to radiate same without first moving 2,000 or 3,000 tons of coke which had fallen around tower, completely burying same from ground level to conveyer support.

No. 2 retort house was built in 1888. The building was of stone, 225 feet 5 inches long, 69 feet 6 inches wide and 26 feet 5 inches to eaves of roof. The original bench installation consisted of 17 half-depth benches of eights, with oval retorts 15 by 24 by 20-foot, through. As with No. 1 retort house, the transition from hand labor to machine operation was the same. Mouthpieces were of the self-sealing type. Stand pipes, 6 inches diameter, hydraulic mains of steel. Tar overflows and tar seals were originally used in this house, when a change later on was made to liquor seals. A clinkering pit, the same as in No. 1 retort house, was used for access to furnaces and recuperators. A DeBrouwer coke conveyer delivered coke into an inclined conveyer adjoining No. 3 retort house. A wooden coal storage bin was erected between No. 1 and No. 2 retort houses, and delivered coal to hoppers of DeBrouwer projectors.

No. 3 retort house was built in 1907. The building was 173 feet 9 inches long by 68 feet 4 inches wide, and 40 feet 6 inches to eaves of roof. This building was of first-class construction, being of steel, brick and concrete. The steel roof had a covering of cinder concrete, water-proofed with plastic asphalt.

The bench installation consisted of 9 full-depth, recuperative benches, of elevens, with D retorts, 15 inches by 25 inches by 20 feet, through. The mouthpiece, hydraulic mains, tar and gas mains were of English design. The coal bunkers were continuous and extended the full length of setting. Two 50-ton per hour bucket-elevators delivered coal from ground floor to 20-inch coal conveyer-belt, located over top of bunkers. A DeBrouwer projector and ram were installed for charging and discharging retorts, and a DeBrouwer coke conveyer delivered coke into an incline conveyer, which, in turn, delivered coke to rotary screen and small storage bin.

This type of retort house had been decided upon as the unit for future extensions, arrangements having been made to extend building and install 9, and possibly 18 more, benches of elevens.

These three retort houses, with the equipment of DeBrouwer charging and discharging machinery and coke conveyers, would be considered an extensive installation. The combined length of retort houses was 624 feet 8 inches; the number of benches was 47; the total number of 20-foot through retorts was 368. For comparison I will state that this installation was equal considering retorts alone, to 92 stop-back benches of 8's.

The daily gas production from all three houses, on 6-hour work, during the winter of 1908, was 3,000,000 cubic feet. In justice to this low production I will state that coal carbonized was not from the Pittsburg district, but was Canadian mined coal.

Owing to the increased yearly gas production, made possible by the expansion and growth of the city of Montreal, it became apparent to the officials of the company that the problem of gas manufacture with the existing retort house installation was becoming serious. The reconstruction of No. 1 and No. 2 retort houses was considered; also an extension of No. 3 retort house by an additional block of 9 benches of 11's. The condition of bench ironwork in No. 1 retort house would not permit of same being used in reconstruction, mouthpieces, standpipes and hydraulic mains being held together more by good luck than by bolts and rivets. The furnaces being small, it was impossible to obtain sufficient heat to carbonize a full retort of coal. The recuperators were practically useless, the secondary air ports in some benches entering the furnace below the furnace arch. In justice to the management I will state that this arrangement of secondary air under furnace arch was an American idea.

All of the retorts in the 19 benches were so badly cracked and punctured with holes that it was impossible to patch same further. In fact, everything pertaining to these 19 benches was practically worn out. When you consider that the greater part of the material, outside of retorts, had been in service for 38 years, we realize that what was left could only be considered as nothing more than junk.

After considering the capital outlay required to reconstruct No. 1 retort house, using the same arches, small furnaces and recuperators, and at the same time considering the tonnage carbonized, with small make of gas per man, it was decided that no reduction in cost of gas could be made, or increase in gas production obtained, unless full-depth benches and larger retorts were installed.

The condition of benches in No. 2 retort house was practically the same as benches in No. 1 house. Hydraulic mains were not only warped and twisted out of shape, but were also spattered full of holes. The bench ironwork was in a similar condition to that existing in No. 1 retort house. Retorts, furnace linings, and recuperators would require resetting inside of 12 months. Owing to condition of hydraulic mains a heavy seal was required to insure against air being drawn in when charging. No arrangement for lowering of seal after charging was used with result that make of gas per ton of coal was affected.

The clinkering pits in No. 1 and No. 2 retort houses were places that will always live in the memory of the men who worked there. With no ventilation, except from the inclined entrance at one end of the house, with the heat from furnaces reinforced by the burning of ½-inch gas pipe torches in front of every other furnace, with occasional backing up of sewers and flooding of pits, the clinkering of furnaces and wheeling out of ashes during winter months constituted a job that polite language is totally inadequate to describe.

---

* Paper read before joint meeting, Canada-Michigan Gas Association, Toronto, September, 1912.

The reconstruction of No. 2 retort house, using a modern design of half-depth benches, and utilizing all bench ironwork that could be recovered, was seriously considered. As No. 3 retort house adjoined No. 2 retort house we would have one house operating from the ground floor and one house operating from a stage floor. Additional coal-handling equipment would be required, and future coke storage (which we had in view) would not be available. The enlarging of clinkering pits would be expensive and as costly as a steel and concrete stage floor. There were too many factors against the reconstruction of No. 2 retort house with half-depth benches. Increased production of gas was absolutely necessary, the make of gas per man would have to be greatly increased, and the cost of gas reduced to warrant the capital outlay. We could not see wherein the perpetuation of half-depth benches would meet above requirements. We, therefore, decided upon another scheme of reconstruction, which has worked out to our entire satisfaction, re-production of gas, make per man, and reduction in cost of manufacture. Before dealing with the reconstruction of No. 2 retort house, a description of No. 3 retort house and a statement as to condition of benches in May, 1909, I believe would be interesting.

As previously stated, No. 3 retort house was adapted as the unit for future extensions. The benches were guaranteed for 2,000,000 cubic feet of gas per 24 hours, on 6-hour work. Each bench contained 11 D-retorts, set vertically in 3 tiers, 4 on each side and 3 in the centre. The centre, bottom retort, or bull's eye directly over furnace, was left out, and one furnace on discharging side of bench heated the setting.

This house was completed, and benches charged, July 15th, 1908. After operating a short time settlement was noticed in retorts over furnace, and this settlement became so great that charges could not be pushed out by ram. It was, therefore, decided to let down the collapsed benches and reconstruct the settings. A change in design was adopted with a view to overcoming this settlement and rupture of retorts. This reconstruction was not satisfactory. The retorts again collapsed, and, in some cases, closed up so completely that it was impossible to get a clinker bar into a retort. Gas could not be produced in this house without further reconstruction of settings.

As it had been decided not to rebuild benches in No. 1 retort house, we were left with only No. 2 retort house for the production of coal gas. With an increased gas consumption of over 10 per cent., the problem of supplying the consumers was becoming serious. Fortunately, the company had a water gas reserve of 2½ million cubic feet per day; but this production was not equal to the combined make of Nos. 1 and 3 retort houses. It was apparent that our only recourse was to increase the capacity of the water gas machines. Altering the time of blow-and-run, increasing steam openings and measuring steam and air used, increased the capacity of water gas machines 100 per cent. Mr. Haug's paper at last year's Quebec meeting dealt with this problem. The increased capacity of the water gas machines permitted us to put No. 1 retort house out of commission.

The reconstruction of No. 3 retort house was, then, our first problem. The two failures of the bench contractor convinced the management of the company that radical changes were required to insure stability of setting. We, therefore, decided to make up our own design and reconstruct with our gas works' staff. A bench of 11's is not a standard design, and careful perusal of gas literature failed to give us a design we considered suitable. A block setting would require too much time in waiting for material. Fortunately, we had in stores several hundred thousand Scotch firebrick, Welsh silica brick, 12-inch brick soaps, splits and arch bricks. It was decided to use these bricks in resetting the benches, as a block setting was out of the question when time was considered.

A design that we believed would overcome collapse and settlement in block setting was adopted. The furnace arch was torn out, carried higher up into combustion chamber, and rebuilt of silica brick. Furnace was widened from arch to grate bars, and relined. The combustion chamber was built of silica brick. The supporting walls for retorts were made of a 9-inch silica brick, and Scotch firebrick. The firebricks were used between side retorts and division walls of benches. The centre of supporting walls, from combustion chamber to main arch, was silica brick. These supporting walls were 9 inches apart, and carried up to main arch where provision was made for expansion. Retorts over combustion chamber were protected with silica brick in a similar way as shield tile are used in block settings. The recuperators, having given no serious trouble, were not disturbed. We have since redesigned and rebuilt recuperators, for we found, after a year's operation, tiles so badly ruptured, due to structural weakness, that short-circuiting of air seriously affected the heat of bench.

After the resetting of benches was completed we had, with the exception of retorts and recuperators, a bench built entirely of 9-inch bricks. This design was a departure from standard block construction, and we were told by bench builders that all manneer of trouble would be experienced.

No. 3 retort house was charged September, 1909, and, with the exception of time consumed in renewing recuperators, has been in continuous operation for 3 years. All of the benches will have a life of 4 years, and we expect to continue some benches on to the fifth year. Up to date we have experienced no settlement of retorts or settings. The retorts are level and true, the division walls and combustion chamber are as sound as when first constructed, and, with the exception of minor patching and repairs, we have had no further trouble or expense with this stack of elevens.

After operating the brick setting for a few months we were so well pleased with the condition of retorts, combustion chamber, supporting walls, etc., that we decided to adopt this type of construction for all future extensions. In the spring of 1910, the benches in No. 2 retort house were in condition for resetting. Having decided against the reconstruction of this house with half-depth benches, our only alternative was extension of No. 3 house as originally contemplated, or complete reconstruction of No. 2 house. The capital outlay required for the extension of No. 3 house we considered too high for a 2,000,000 coal gas unit. The walls and roof of No. 2 retort house were sound, but height of walls to eaves would not permit installation of stage floor benches. Floor space was ample for 18 benches of 8's, which would produce 2,500,000 cubic feet of gas per day on 8-hour work, or 3,000,000 cubic feet on 6-hour work.

As No. 2 retort house adjoined No. 3 house the reconstruction of same to make one continuous building was cheaper than proposed extension to No. 3 house. Yard space for present storage of coke and future storage of coal, would be reduced if extension to No. 3 house was adopted. We, therefore, decided upon the reconstruction of No. 2 house and the installation of 18 full-depth benches of eights.

The walls of building were 26 feet 5 inches to eaves of roof. As roofs to both houses were to be continuous, it was necessary to increase height of walls 14 feet 1 inch. The old roof was first cut in three sections; one section at a time was raised by chain-blocks attached to gin poles.

Brick walls were built up on old stone walls to a height level with wall plate of No. 3 house. As walls were completed, roof sections were lowered into position, riveted together and connection made to roof over No. 3 house. The roof covering was made of a thin layer of concrete, waterproofed with plastic asphalt.

The bench installation for new house consisted of two stacks, each stack containing 9 benches of 8's.

The brick setting in No. 3 house having worked out satisfactorily, we decided to adopt brick construction entirely in the settings of eights. The material used in furnace arch, combustion chamber and supporting walls of retorts was the same as used in the setting of elevens, but a change in design of combustion chamber was necessary, owing to the centre row of retorts being left out. The retorts were of Glenboig material, D-shape, 16 inches by 26 inches by 20 feet, through, set in two vertical tiers of four. The combustion chamber was built directly over furnace arch, and extended the full length of setting. The secondary air entered combustion chamber through flues opposite each nostril hole in furnace arch. Silica shield tile protected sides and bottom of retorts next combustion chamber. The furnace, located on discharging sides of bench, was of ample size to evenly heat the setting. Special attention was given to design of recuperators to minimize short circuiting of secondary air. The flue gas was led from recuperators into a main flue 4 feet wide by 4 feet 6 inches high, which extended the full length of setting and connected to chimneys at each end of house. The 4½-inch firebrick bottom of flue was laid directly on top of foundation. A 4-inch wall or mid-feather was built in centre of flue and extended the full length of same.

The stage floor was level with floor in No. 3 house, the charging side being made up of steel beams with checkered steel and cast-iron floor plates. The discharging side floor was made up of steel beams filled in with reinforced concrete. Mouthpieces on charging side of bench were 20 inches deep, and 7 inches on discharging side. Tar aprons were attached to mouthpieces with the exception of bottom row. The 8-inch ascension pipes and hydraulic mains were on charging side only. The discharging side was free from ascension pipes, hydraulic mains, etc. As gas was taken from retorts on charging side, the mouthpieces on discharging side were at all times free from tar. We were, therefore, not troubled with tarry and spongy coke, which is generally formed in and around the mouthpieces. Another advantage gained was reduction in cost of hydraulic main equipment and saving in pipe men on discharging side of house. Stopper men were dispensed with by allowing spongy coke pushed over into discharging mouthpiece to remain as a stopper for the charge from projector. This spongy coke was converted into dry coke during the next period of carbonization.

The coke was delivered into a DeBrouwer conveyer, which, in turn, delivered coke into incline conveyer connected with No. 3 retort house. Each bench had an individual hydraulic main. To each hydraulic main was attached a 10 by 10 weir valve for outlet of gas and regulating depth of seal. This weir valve was connected to 24-inch foul gas main, which extended the full length of setting and joined a header main connecting to 30-inch foul gas main on wall of building. At junction of header main two 16-inch retort house goverenors with by-passes were installed, and two clean-out pockets for removal of heavy tar were attached to each hydraulic main. A 4-inch tar outlet at bottom of hydraulic main connected with 10-inch tar main, which extended the full length of setting, and delivered tar and liquor into tar tower. A weir valve at tar tower was also used to regulate depth of seal in hydraulic mains. The liquor overflowing from tower passed into tar and liquor separator in cellar of retort house. Liquor was pumped from receiving tank connected to separator back into hydraulic mains. The accumulated tar in tower was drawn off every hour and flowed into tar well. Continuous coal bunkers, of 24 hours' capacity, extended the full length of stack on the charging side of benches.

The results obtained from 8-hour work in No. 3 retort house were so satisfactory that we decided to adopt 8 hours as the time of carbonization for all charges of both houses.

With the DeBrouwer projector we were able to charge the retorts full, thereby reducing the area of retort exposed to the gas. The time contact of gas with crown of retort was reduced to a minimum, which resulted in eliminating stoppages of ascension pipes and pitched hydraulic mains.

The coke (produced from Westmoreland slack coal) was very large and hard, closely resembling oven coke. This was due to increasing time of carbonization and full charges in retorts. Coke handling equipment, consisting of crusher, screens, bins, skip hoist and belt conveyers, now being installed in No. 1 retort house building, will give us an overhead inclosed coke storage of 4,000 tons capacity.

The total cost of reconstructing No. 2 retort house, including alterations to building and complete retort installation, was approximately $140,000. The production of coal gas was increased from 3,000,000 cubic feet per day to 4,000,000 cubic feet per day on 8-hour work, or 5,000,000 cubic feet per day on 6-hour work. The work of reconstruction and the dismantling and abandonment of No. 1 retort house at the cost indicated, were amply justified by the resultant increased production of gas and reduction in cost per 1,000.

◆

MERGER OF BRIDGE COMPANIES IN MONTREAL.

The latest merger spoken of here is that of the Dominion Bridge Company and the National Bridge Company. The expectation is that the Dominion Bridge Company will buy the National out, and that following this there may be an issue of the stock of the Dominion Company and that this may be listed on the local stock exchange where the public may buy and sell it as in the case of other stocks. There can be no doubt that Dominion Bridge would be one of the popular trading stocks as the company has been so well known for many years past and has been unusually progressive and successful.

The National Bridge Company has a capital of $1,000,000 common stock and a bond issue of $560,000 of 6% first mortgage, 40-year sinking fund bonds. The plant has only been in operation since July 1st, 1911, and a year after it had begun was turning out a total of 1,300 to 1,400 tons per month.

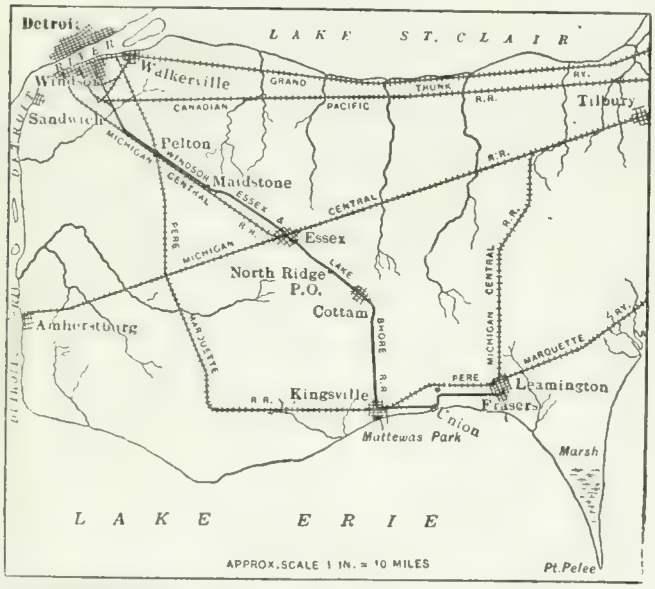
It is the owner of 350,000 feet of land and a plant at Longue Point, near the city, and although its plant is operating to full capacity it is quite unable to keep up with the orders which are coming in from all quarters. There are now orders in hand, it is claimed, to keep the plant going until well into next year.

Not the least remunerative of the assets of the company must be an option possessed on a block of 560,000 feet of land adjoining its own property. This option has till next April to run and land has been increasing at a very rapid rate in value in the vicinity mentioned.

It is stated that the Dominion Bridge Company will guarantee the interest on the National Company bonds and give one of its shares for four of the National shares. The directors of the National are Messrs. J. N. Greenshields, K.C., president; William Lyall, W. G. M. Shepherd, Hon. R. Mackay and H. W. Beauclerc.

THE WINDSOR, ESSEX AND LAKE SHORE RAPID RAILWAY.

The Windsor, Essex & Lake Shore Rapid Railway is a single-track line extending from Windsor to Leamington in the province of Ontario, with a total trackage of 40 miles. The line has been operated since 1908 and has the distinction of being the first and only single-phase railway in Canada. A very full description of the line was given in a recent issue of the Electric Railway Journal; this abstract is prepared from that article. The operating conditions are simple, as may be judged from the fact that the country is of level character with the exception of a 5 per cent. grade near Kingsville. Twenty-six miles out of the 37 miles of route are on private right-of-way, but in spite of this there are few curves. The following paragraphs will present some figures on the maintenance cost of the electrical features of this road and also a description of the freight and passenger business development.



Routes of Windsor, Essex & Lake Shore Railway and Nearby Steam Railroads.

The line construction is of the catenary type with cross-span suspension in towns. The poles are 120 ft. apart on tangents and as close as 80 ft. on curves. The material is of Westinghouse standard type, consisting of a steel messenger wire with hangers spaced 10 ft. apart, No. 000 grooved trolley wire, wooden-arm steady strains at curves, etc. In general the line is anchored at every thirty poles. This catenary carries current from the power house to the substation at Madisone, 18 miles distant, at 6,600 volts, which voltage is also used for the trolley service throughout.

The maintenance records for 1908 and 1909 do not show the charges made specifically for the upkeep of the line and bonding, but for the following fiscal years ended June 30 the amounts spent were as follows: $2,084.26 for the year 1910; $1,650.79 for 1911; $1,808.58 for 1912, a total of $5,543.63, or an average of $46.19 per mile per annum. Other figures by months were as follows: July, 1911, $174.66; July, 1912, $[illegible]; August, 1911, $179.5[illegible] and August, 1912, $145.53. These figures are not chargeable entirely to line and bonding account because the three linemen have plenty of time available for other work. The excellent behavior of the catenary construction will be best appreciated from the fact that in nearly five years of service only one or two wire breaks have occurred and it has been unnecessary to replace any material whatsoever. Most of the expenses charged were due to the installation of additional material such as strains at curves, hangers, switches, etc. Pantograph current collectors are used, and it is figured that the trolley wire is good for three to five years more. It is probable that the replaced line construction will consist of a copper catenary and a steel trolley wire. The snow-fighting equipment consists of an ordinary flat car which was fitted with nose plows at each end.

It has not been found necessary to make any track replacements or the like, but the roadway has been greatly improved by being reballasted with spoil from the company's gravel pits.

The generating equipment of the power house at Kingsville consists of two Goldie-Corliss cross-compound engines, operated at 125 r.p.m. and direct-connected to 500-kw., 25-cycle, 13,000-volt single-phase generators, which are furnished with 6,600-volt taps for the trolley line. These engines have required so few repairs that the total expense for five years' operation has been less than $50. The repair expense to the generators would be covered by about $100, the cost of four or five coil burn-outs.

Perhaps the most interesting feature of the station is the use of natural gas for the four 360-h.p. Canada water-tube boilers. Each boiler has seven Gwynne burners which have three cocks whereby the amount of fuel supplied to the boiler is regulated as easily as with a domestic gas stove. A slide valve at the end of each burner tube is manipulated to change the air mixture until a perfect blue flame is secured. The gas is obtained from the wells at 500-lb. pressure and is reduced to 8-oz. pressure at the boilers. Its fuel value is 11,000 b.t.u. per cubic foot. The boilers are operated at 140 lb. to 150 lb. steam pressure. The amount of attendance which these boilers need is so little that only one night man and one day man are required except for the occasional help of a cleaner from the engine room. In fact, the entire staff of the boiler station consists of but three day men and two night men. The use of natural gas as fuel has also proved an excellent thing from the maintenance standpoint because so far no replacement material has been required except a few bricks for the settings.

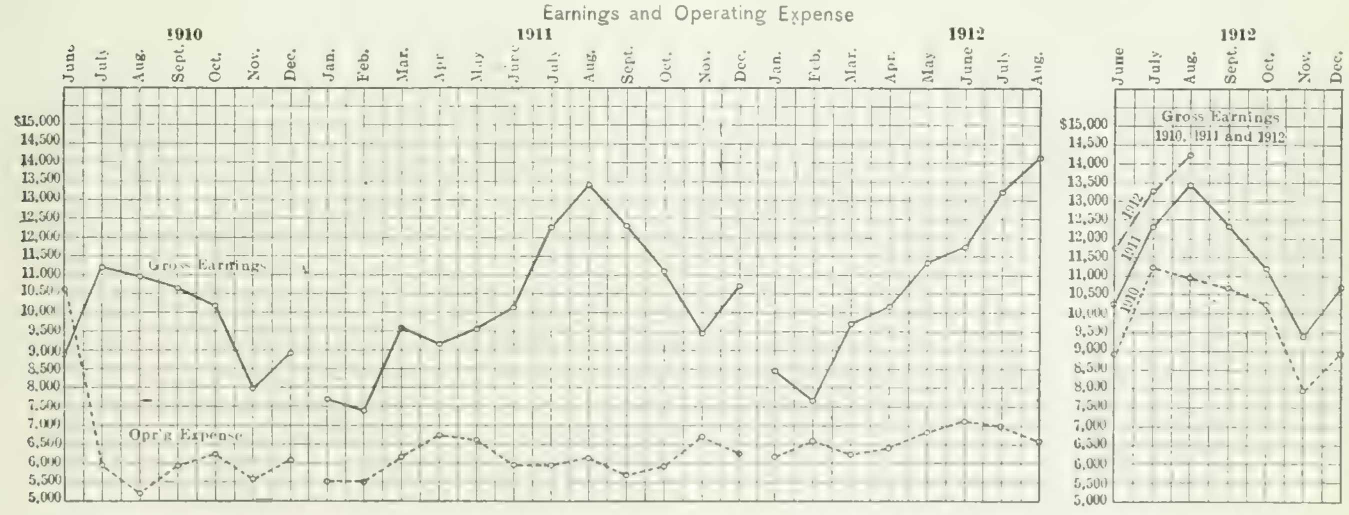
The original rolling stock consisted of five 55-ft. interurban type motor cars, four passenger trailers formerly used in elevated railway service, two baggage trailers and one electric locomotive. The passenger cars are each equipped with two 100-h.p. Westinghouse-132 straight single-phase motors, and the electric locomotive has four 100-h.p. motors of the same type. A similar equipment of four 100-h.p. motors has been furnished for the new combination express and locomotive car. The company also keeps four spare motors on hand. In general, the motors have always proved capable of meeting the conditions for which they were designed except that under excessive overloads they do not accelerate so quickly at a d.c. motor. The only trouble given by the original type was due to the breaking off of the thin leads at the commutator. The original coils were therefore replaced with coils with thicker tips, and no further trouble has been experienced. The company does all its coil winding and baking and also slots all commutators. The pantograph shoes are home made.

For the year ended June 30, 1911, the cost of maintaining the electrical equipment of the cars was $6,793.47 and for the following fiscal year $4,899.88. During the fiscal year ended June 30, 1911, the company operated 266,063 passenger miles and 80,903 freight and miscellaneous miles, making a total of 346,966 miles, and for the following year 273,380 passenger miles and 85,223 freight and miscellaneous miles, making a total of 358,603 miles. Approximately 2 per cent. of the passenger mileage included trailer service. In accordance with these figures the maintenance cost of electrical equipment of cars was $19.57 per 1,000 miles for the year ended June 30, 1911, and $13.66 per 1,000 miles for the year ended June 30, 1912. It is believed that the cost will be appreciably less during the next few years, owing to the change in armature coils and because the cars have been thoroughly overhauled during the past few months. The company feels that it has every reason to be satisfied with the behavior of the car apparatus.

The company operates nine passenger trains a day each way between Windsor and Leamington, a distance of 36.6 miles, and one extra passenger train each way between Kingsville and Leamington, a distance of 8.7 miles. Two of these trains are limiteds except on Sundays, when all trains are locals. The local trains make the run from Windsor to Leamington in one hour and forty-five minutes and the limited trains in one hour and twenty-five minutes. The institution of limited train service increased the company's passenger business about 20 per cent.

In addition the company operates each weekday two express and freight trains each way. These are scheduled to make the trip between Windsor and Leamington in two hours and ten minutes in one direction and one hour and fifty-five minutes in the opposite direction. Before December, 1911, less-than-carload express and freight service was run with passenger cars to form an accommodation train. This service hindered the passenger business to a great degree, and the running time between Leamington and Windsor was two hours and fifteen minutes. This train was therefore replaced by the limited service mentioned, and arrangements were made to handle the less-than-carload business by the new combination express and freight car, which also hauls standard freight cars twice a day on regular schedule. The latter arrangement saves a great deal of mileage as compared with the former method of having a locomotive make a special trip for individual freight cars. The old locomotive formerly used for freight service is now employed for general utility service, including the hauling of passenger trailers, as shown in one of the accompanying illustrations.

Locomotive Car with Four Trailers.



Curves Showing Ratio Between Gross Earnings and Operating Expenses, and Increase in Gross Earnings.

As noted from the mileage figures previously quoted, the company does considerable freight business, most of which consist of local products like tobacco, grain, hay and live stock. Besides handling local business the company has through billing arrangements and physical connections with the Canadian Pacific and Père Marquette Railroads, with which it prorates in accordance with the regular steam railroad classification. Where there is competition with the steam railroads the electric railway usually gets the business because it gives two deliveries a day compared with one delivery by the steam railroads. The freight business has been built up by personal solicitation among the local men, who are asked to specify the electric railway for all through routing.

The company has a large freight terminal at Windsor, a transfer station at the junction with the Canadian Pacific Railroad, a freight house at Leamington and a yard for live stock at Cottam. It has recently completed at Essex a handsome combination passenger and freight station. The station building, 32 ft. x 27 ft. 4 in. in area and constructed chiefly of brick, contains a waiting room and offices. It is adjacent to a corrugated-iron freight shed, which is 52 ft. long at the wagon delivery side and 41 ft. long at the track platform side.

On this line the growth of the freight business is merely a question of facilities. Thus the new express car has already secured a great deal of new business, and it is believed that the new depot at Essex will increase the earnings from this branch by about 50 per cent. It is likely, therefore, that additional sidings and freight houses will be built in the near future.

The improving financial condition of this property is indicated by the fact that the operating expenses for the fiscal year ended June 30, 1911, were 63.27 per cent., and for the fiscal year ended June 30, 1912, 59.52 per cent. of the gross earnings, in spite of the large amount of rehabilitation. The curves show by months how the gross earnings have increased and the proportion of operating expenses has decreased since June, 1910. The improvements have been made under the direction of Albert Eastman, general manager, who created and built up the freight and express business of the Utica (N.Y.) & Mohawk Valley Railway before assuming the management of this property.

EFFECT OF TRAFFIC ON BITUMINOUS PAVEMENTS.*

By Isaac Van Trump, Engineering Chemist, Chicago.

A new problem has arisen within the past year or two which the paving engineer must solve, and that is the deep ruts formed in bituminous roadways under exceedingly heavy motor traffic. The writer has in mind two boulevards, paved about 12 years ago with sheet asphalt. Until less than two years ago these thoroughfares were, after 11 years of constant traffic, still in perfect condition. During the summer of 1911 slight ruts appeared in the pavement, gradually becoming deeper until during the past hot season it became almost dangerous for a fast moving vehicle to use that portion of the street. In the writer's opinion this pavement, which had for 11 years been perfectly hard and stable, gradually became softened and displaced under the tremendously increasing automobile traffic and the minute oil drippings. It has been estimated that 17,000 vehicles, principally automobiles, pass over these pavements each day, a large percentage of which are homeward bound between the hours of 4 and 7 p.m., when the pavement, especially during the summer, is still warm and yielding from the hot sun.

It is, of course, well known that asphalt pavements become harder with age, but on the two boulevards above mentioned the condition of the pavement after years of service is reversed and it is now the problem of the paving engineer to prepare and lay a bituminous pavement which will not be seriously affected by the minute but constant dripping of oil and gasoline from automobiles. Neither is the above condition confined to sheet asphalt alone, as a similar condition existed on another portion of one of these same boulevards, paved in 1907 with bituminous concrete containing a coal-tar binder. Deep ruts appeared in this pavement within two years after laying, making it necessary to resurface the entire roadway.

Some few municipalities are advocating the elimination of the binder course. In many instances to economize in this manner is a serious mistake. A dense binder not only acts as an anchor for the wearing surface by giving added rigidity and stability to it, but it also protects the upper surface to a considerable degree from the deleterious action of water and illuminating gas from beneath. Many concrete foundations exude moisture under certain atmospheric conditions. The opportunity for street liquids to get beneath pavements from along car tracks, gutters and headers, and around manholes and catchbasins is great. Where no binder is employed, these liquids have easy access to the under side of the wearing surface.

To prevent the wearing surface from creeping under traffic some municipalities substitute a paint coat in place

---

From the Valor World, October, 1912.

of a binder course between the concrete base and the surface mixture. Theoretically a paint coat forms a perfect bond between the two courses, but at best it is difficult and inconvenient to prepare and apply, and unless the conditions on the street are ideal the practical results are frequently entirely different from those obtained in theory.

Also for the purpose of overcoming the tendency of the wearing surface to shove under traffic, several cities have recently adopted what is known as "anchor concrete," a form of construction patented by W. B. Brady, of Chicago. Anchor concrete is merely a slush coat of cement mortar spread ⅜ in. deep upon the freshly laid concrete foundation. Before this slush coat has received its initial set, clean, hard, broken stone about 1½ to 2 in. in diameter is spread evenly over it and imbedded into the slush coat by light tamping. When dry, this produces a very rough but rigid surface and acts as an anchor for the topping which is laid directly upon it. This form of construction is especially effective on steep grades.

Where the traffic is light, such as on suburban or residential streets, it may be possible to eliminate all forms of intermediate courses and lay the wearing surface directly on the concrete base, but to do away with the binder course generally, as a few municipalities have recently done, regardless of traffic or other conditions, is a serious error.

STANDARD METHOD OF TRAFFIC RECORDING.*

The object of this report is to suggest a uniform method of recording, analyzing and standardizing quantity and weight of traffic on streets and roads, and for reducing it to unit bases of quantity and of tons per yard of used traffic width of roadway per day, or per square yard of used roadway surface, which it the same thing. It is wise to recall the two legitimate causes of wear and destruction of pavements; they are traffic and weather, separately and combined. Many records of traffic have failed to state the width of the road and are defective in other respects. Many cannot be reduced to any unit basis for comparison with one another. Many have unnecessarily subdivided the vehicles into too many kinds, sizes, etc., by methods which are complicated and unnecessary for practical, general use. Traffic records should be based on a simple, accurate method of counting and recording traffic and reducing it to standard units of quantity and tonnage. The method should be such as to be quickly understood and applied.

The period during which traffic should be counted is for 12 consecutive hours from 7 a.m. to 7 p.m. and during six consecutive or other different week-days. If average weather and what is known to be average traffic conditions are selected, then a record for only three consecutive week-days gives valuable information. No traffic should be counted in abnormal seasons of snow and ice, nor during continuous rainy, very cold or excessively hot days. The traffic should be counted at or near the centre of a block and not at an intersection of two streets. The traffic is that which passes both ways along the street or road.

The general classification of vehicle traffic for practical results, is as follows: First, horse vehicles, subdivided for vehicles drawn by one, two and three or more horses; second, auto vehicles. The vehicles and horses must both be considered in computing the weights of traffic from the quantities counted and recorded. For general traffic counting and the reduction of the quantities of vehicles to tonnage of traffic, the average weight of all vehicles, empty and loaded, drawn by one horse can be taken as 1 ton of 2,000 lb.; by two horses as 2 tons; by three or more horses as 4 tons. In like manner the average of all auto-vehicles, loaded and empty, for transportation of persons and goods can be taken as 1¾ tons. All bicycles and ridden horses, because light and very few, are best omitted from street traffic recording.

For recording traffic, sets of four cardboard slips, about 9 x 2 in., fastened together at the end, may be used; twelve sets are needed. One set is used for each hour. Each set is marked for location where traffic is counted, name of observer, date, the hour represented by the set (as 7 a.m. to 8 a.m., etc.). There must be at least two observers for each location, to relieve each other at the end of each hour or two hours, because one recorder cannot work accurately for a longer period. An ordinary conductor's punch is needed and a hole is punched in a slip for each vehicle passing in either direction along the street in front of the recorder. One-horse vehicles are punched on white cardboard; two-horse on yellow; three and more horse vehicles on red; all auto vehicles are punched on blue slips.

A blank form for one-day traffic record consists of a consolidated record of the quantity of traffic during each of the twelve hours from 7 a.m. to 7 p.m., with totals and reductions to unit bases. It gives details of name of city, width of roadway, effective width used by traffic, which averages ½ yd. less on each side or 1 yd. less than the full width between curbs or edges of the street, the kind and quality of pavements, the weather and other needed facts are shown. This form reduces the one day's traffic to standard units which are the total vehicles and total tons of traffic on the whole street; also per yard of effective width of the street. This is the equivalent of number of vehicles and tons per square yard of used roadway surface.

From the forms for the one-day traffic records a consolidated traffic record is compiled. It consists of a condensed statement covering the six or other number of days' traffic. It shows the data day by day, together with the final totals and the average per day. These totals are reduced in quantity and tons to the standard units of yard of effective width (square yard) of roadway surface subjected to the traffic. These are the true bases for comparing the traffic of one street with another and for establishing the relation of different amounts of traffic to wear on pavements, cost of maintenance and for many other useful purposes.

Traffic records are seldom needed annually; but at longer intervals up to once in five years or according to local conditions.

NOVEL METHODS OF HAULAGE.

During the operation of excavating for the foundations of large buildings it is a familiar sight to see an additional team whose duty it is to assist the haulage of the earth wagon to the road level, but this method has been superseded by a donkey engine at the corner of Simcoe and Richmond Streets in the city of Toronto.

The donkey engine is located on the roadway at the top of the incline, which is exceptionally steep, and uses the curbing as a brace. When a wagon has been filled and moved by the horses to the bottom of the incline, a cable is let down and secured to the tongue of the wagon by a hook; the horses are started on the upward path as the throttle is opened and it is interesting to see mechanical horse-power pitted against the more fleshy nature. If any conclusions are to be drawn from the action of the horses a by-stander would take it that the horses imagine they are on an elevator.

* Committee report of J. W. Howard, consulting engineer, New York, chairman, presented before American Society of Municipal Improvements, Dallas, Texas, Nov. 12-15.

REPORT ON WATER SUPPLY AND FIRE-FIGHTING APPLIANCES OF VICTORIA, B.C.

An exhaustive report on the water supply and fire fighting appliances of the city of Victoria and district has been prepared by Mr. H. R. Page, secretary-treasurer of the Vancouver Island Fire Underwriters' Association.

The report expresses the opinion that a conflagration hazard exists in Victoria owing to the narrowness of the streets in some instances, and the congested condition of a number of the mercantile blocks, which are solidly built up and lack lanes or other modes of access to the rear of the buildings.

The report considers there is no conflagration hazard in Oak Bay, but the abandoned shacks at Wharf Street, Esquimalt, are a danger.

The fire losses, the report says, have been rather severe during the past few years, the losses paid by insurance companies being as follows:—

1909	$ 74,435 00
1910	582,975 00
1911	128,377 00
1912 (to end of October)	128,584 00
Total	$914,471 00

or roughly calculated, slightly more than 60 per cent. of premiums received during the same period.

The Victoria city council decided to refer the report to the fire wardens, fire chief and water commissioner.

The mayor remarked that they would search in vain for any reference to the reduction of premiums. They had doubled in the last 18 years, steadily advancing from time to time as the city improved the fire brigade equipment.

The following findings of the report contain the observations of Mr. Page on the application of the city's apparatus to cope with an emergency:—

"The consumption has outgrown both the supply and capacities of the supply mains and pumps; at the present moment, with the Beaver Lake and North Dairy pumping stations in operation to the limit of their output, which equals approximately 4½ million gallons per 24 hours, there is a gradual drop of the water stored in Smith's Hill reservoir.

"This during a season when the consumption is probably at its minimum, promises a serious condition of affairs during the coming summer unless some provision is immediately made for increasing the supply.

"Further, the supply mains mentioned in this report are single lines, and have been laid for a period of 20 years or more, also the pumping units are not in duplicate, and should the larger pump at the North Dairy station, which has been steadily in commission for the past year, become inoperative through any cause, the city, or a large portion of it, would be without water for domestic purposes.

"The attention of the civic authorities has been drawn to these matters at different times during the past three years, and beyond repairing of the reservoir no material improvements have been made towards insuring an adequate domestic supply.

"It is proposed, and the work is at present under way, to bring water from Sooke Lake, some 27 miles distant; but this work, at the present rate of progress, will not be completed before 1914. It therefore becomes necessary to make some temporary provision, the two most feasible propositions being to lay a new supply main from Elk Lake to Smith's Hill reservoir and install additional pumping machinery at the North Dairy station, or connect the 36-inch main now laid on Gorge road with the Esquimalt Water Works Company's main. Should the latter course, which would appear the most simple, be adopted, the actual work of connection could be completed within two months, but under their charter the Esquimalt Water Works Company are privileged to demand 15 months' notice before such connection can be made, and also that a minimum of 500,000 gallons of water per day, at the rate of 6c per thousand gallons, be accepted for a period of not less than five years. Taking it for granted that the period of notice be waived by the company, and that the joint trouble in their supply main has been remedied, and considering that the head is sufficient to supply Smith's Hill reservoir without recourse to pumping, and the quality of the water unquestionably superior to that of Elk Lake, the latter proposition should be preferable.

"A large percentage of 4-inch pipe has been laid in James Bay district, and the section between Hillside, Tolmie, Victoria and Sidney Railway and Cook Street being particularly bad in this respect.

"The hydrants in some dwelling sections are widely scattered, while in the outlying business area the distances between hydrants runs as high as 500 feet. In such blocks intervening hydrants should be installed.

"When taking pressure tests, a number of hydrants were found in poor condition, three within the business area being entirely out of commission. A thorough inspection is recommended of all hydrants and also that all faulty ones be replaced by an approved pattern of hydrant having a steamer connection, and also that where the main permits, the branch connections be not less than 6-inch.

"Service mains running parallel on Wharf, Government, Douglas and Blanchard Streets would be materially assisted if cross connected, say, at Discovery, Cormorant and View Streets, also more gate valves should be provided; under present conditions a break in any one of these pipes during fire service would cause serious delay owing to the distance apart of the salt water hydrants in an easterly and westerly direction.

"As before stated, the salt water mains, when not in commission, are kept filled with fresh water and connected to the domestic system. In order not to waste the 65,000 gallons required to fill the system after service, the high pressure pumps are not started until a second alarm is sent in. As the steamers frequently connect to the high pressure hydrants for suction, there would appear to be a possibility of serious consequences in the event of a fire getting out of hand during the interval between releasing the steamer and changing the hose lines to the salt water hydrants. However, this is a matter that will be remedied when the scarcity of fresh water ceases to be a factor for consideration.

"The wires carrying the current from the British Columbia Electric sub-station to the salt water pumping plant should be in duplicate and underground in conduit, and kept live at all times, thus doing away with the manual agency at the sub-station. These wires should also enter the pump room direct, without passing through workshop and room in which the distributing tower is located.

"At time of inspection the North Dairy pumping station was practically without fire protection, one fifty-foot length of hose without a nozzle being the only equipment on hand. The two adjacent fire plugs should have hose and nozzles permanently attached.

"This department has kept pace with the growth of the city, the equipment being fully modern and organization good. The strength of the brigade has doubled in the past three years.

"The headquarters station is located in a poor class of building, originally constructed for a market. This constitutes a serious hazard to the alarm system, the central station of which is located at this building. Should a new fire hall not be contemplated within reasonable time, it would be as well to have the alarm equipment housed in a separate fireproof building.

"The city by-law re electric wiring is incomplete and elastic, the system of inspection inefficient; on the whole, however, the new work is comparatively good, but a large amount of old wiring should be condemned.

"The building by-law recently adopted covers the ground fairly well, but makes no provision for mandatory protection of exposed openings in district B. This is an important feature, especially in blocks having no lanes, and where buildings on either street are built back to within a few feet of one another.

"The building inspector's department is apparently understaffed, and during the busy season unable to carry on the necessary supervision, but I have at all times received most courteous attention when reporting any defects."

◆

THE DEVELOPMENT OF DIESEL MARINE OIL-ENGINES.

Among sundry notices that have recently appeared in the press about new engine works for the development of Diesel oil engines for ocean-going ships, little notice has been taken hitherto of progress made in this direction on the River Tyne. Messrs. Swan, Hunter & Wigman Richardson, Limited, at their Neptune Engine Works, Walker, Newcastle-on-Tyne, have for some years been actively engaged in studying and developing Diesel oil engines.

Diesel-engined Ships.—Two years ago they completed a twin-screw cargo ship called the "Toiler" which has the distinction of being the first oil-engined vessel to cross the Atlantic. She is owned by Mr. James Playfair, of Midland, Ontario, and trades in the Great Lakes of North America. Her builders at once followed up the "Toiler" with another similar twin-screw cargo steamer for the same owner. The vessel is called the "Calgary," and has greater engine power than the "Toiler." She has been safely delivered at her destination in Canada, and trades on the Great Lakes. Messrs. Swan, Hunter & Wigham Richardson, Limited, are now engaged in the construction of two much larger cargo boats for British owners, and carrying about twice the deadweight of the "Toiler" and "Calgary."

Electric Transmission.—In addition to these ships the same builders have in hand another interesting ship being built for the Montreal Transportation Company, of Montreal. This will be the first large vessel designed for propulsion by power transmitted electrically from the engine to the propeller. The designs of the engines have been executed by Mr. Henry A. Mavor, of Messrs. Mavor & Coulson, of Glasgow, who have already tried this system on a small experimental vessel called the "Electrical Arc." The deadweight cargo capacity will be about 2,500 tons. The machinery will consist of two 300-h.p. high-speed Diesel engines, each with its own alternating current generator and exciter. Just ahead of the thrust block there will be a specially designed motor operating a single propeller, and reducing the 400 revolutions per minute of the Diesel engines to about 80 revolutions per minute. Among the advantages claimed for Messrs. Mavor & Coulson's system of electrical transmission it may be noticed that the total power of the propelling engine required in a single unit for direct drive can be split up into several sub-units, each with its own generator, all connected to a single propelling motor. Furthermore, all reversing and speed changes can be done by switches, and the electrical control station can be placed in any convenient spot in the ship, e.g., on the navigating bridge, in the engine-room, or elsewhere.

The "Neptune-Diesel" Engine.—Messrs. Swan, Hunter & Wigham Richardson, Limited, have for some little time been developing two-stroke cycle Diesel engines. Various well-known designs of this type of engine have been critically examined and the details exhaustively analyzed. The outcome of all this study has resulted in the "Neptune-Diesel" engine, which for marine purposes is claimed to be second to none. The resign is substantial in its strength, no undue risks being taken by imprudently cutting down weights. Another leading feature is much greater simplicity than is found in many Diesel engines. This means a smaller prime cost and less expense in running and maintaining the engine. The builders have also aimed at easy accessibility to all parts of the engine, which is of the highest value, if ever repairs are necessary. Several radical improvements have also been introduced in the valve gear, pistons and cooling arrangements, all of which are distinctive features in the "Neptune-Diesel" engine.

New Engine Works.—The Neptune Engine Works, which have been established since 1879, have been frequently enlarged and improved, and the best of modern machines have from time to time been installed to replace older tools. Partly in order to develop the "Neptune-Diesel" engine more successfully, and also owing to the general expansion of business, Messrs. Swan, Hunter & Wigham Richardson, Limited, have now embarked upon a complete reorganization of their engine works. This department is to be moved to another site within the Neptune shipyard, and entirely new shops are being erected. The present buildings of the engine works will be used for the shipyard blacksmiths, plumbers and angle-smiths. For some months Messrs. Swan, Hunter & Wigham Richardson, Limited, have been busy clearing a plot of ground of about three acres in extent, with a splendid river frontage. The old Anglesey Cooper Works of Messrs. Henry Hills & Sons formerly stood on this spot. These buildings have been entirely pulled down, chimney stacks demolished, and fresh foundations laid for the new engine works. These new buildings will touch the existing boiler shop of the firm, which is a lofty building 220 feet long by 120 feet wide. The whole of this department for building both engines and boilers will then be at the north end of the Neptune shipyard and will be adjacent to the dry dock department of the firm, giving further splendid facilities for executing repairs to ships and engines with rapidity and economy. Mr. David Purdie, of Shields Road, Newcastle-on-Tyne, has the main contract for piling and excavating.

The new engine buildings are being built of brick and galvanized iron, with glass roofs, most of the work being undertaken by the Clyde Structural Iron Company, Limited, of Scotstoun, Glasgow. Apart from smaller erections the main building will measure about 300 ft. by 200 ft, divided into six bays, and comprising a combined machine and erecting shop. A considerable amount of modern machinery of the latest and best designs will be installed. A new railway siding is being made and the lines from the North Eastern Railway Company will be led right into the shop so as to facilitate the discharge of material coming from distant parts. The river front is being furnished with a completely new jetty making a deep water berth for ships lying alongside. This new wharf will be extended along the front of the Neptune north yard and will be joined to the older portion, making in effect a fitting out berth 1,800 feet long. The existing 80-ton sheer legs at the old Neptune Engine Works quay will be used to help the completion of ships after they are launched. The 150-ton floating crane "Titan," belonging to Messrs. Swan, Hunter & Wigham Richardson, Limited, will be mainly used to lift sets of engines entire from the new engine works quay into ships. This, of course, means a very great economy, saving a great deal of labor in dismantling and re-erecting an engine. This is another example of the splendid and powerful modern plant possessed by these builders. The utility of their floating crane "Titan" has been much appreciated by other firms, for it is frequently hired for lifting heavy weights on board warships and merchant vessels, and it has also been sent to neighboring ports for harbor work, such as lifting and laying concrete blocks, drawing piles, etc.

COAST TO COAST.

Kingston, Ont.—The building permits of this city for the month of November last show an increase of 675% as compared with the same month in 1911.

London, Ont.—The report of Prof. Angus, Toronto, on the cost of lighting the streets of London, is now in the hands of City Clerk Baker. Mr. Angus in this report states that the sum of $19,000 is adequate for the service rendered the city. This is about $1,000 larger than the cost as estimated by Ald. Richter, and just $11,000 less than the amount charged by the water commissioners at the present time. Mr. Angus, in his statement, includes profits, which he figures at $2,000. This is a trifle more than 10 per cent., which is not a bad profit for hydro-electric, all things considered.

Merriton, Ont.—The Riordon Paper and Pulp Co., will undertake the erection of a large new plant at Merriton, Ont. A site has been selected near the present mills and the outlay will amount to about a million and half dollars. The company is capitalized at $6,000,000 and recently $1,500,000 bonds were issued for improvements and extensions to the various plants of the company. At Hawkesbury, Ont., extensive enlargement is now under way, and the daily output of 100 tons of dry sulphite pulp will be increased by 40 per cent. Two new digesters, each of 12½ tons capacity, are being installed. A new digester, house, a new boiler house three new acid towers, and additions to the wood room and shipping room are being rushed to completion. The sulphite mill at Merriton has a capacity of twenty-five tons of moist sulphite pulp per day; twenty-one tons of ground wood-pulp and about the same amount of wallpaper and building paper.

Gaspe, P.Q.—H. Hilyard, of Dalhousie, N.B., acting on behalf of the St. Maurice Lumber Company, has acquired all the properties of A. W. Carpenter, of London, England, formerly carrying on business at Gaspe Basin, under the title of the Gaspe Lumber and Trading Co. The purchase price is understood to be in the neighborhood of $250,000, for all the holdings. The trustees, the Charing Cross Bank of London, took over the property after the failure of Mr. Carpenter. Mr. Hilyard will immediately proceed to develop the property at Gaspe, and it is understood that the construction of a large sulphite mill will be commenced. Included in the property acquired are the wharves of the Gaspe Lumber and Trading Company which command the best situation in Gaspe harbor. The Atlantic Quebec and Western Railway which Mr. Carpenter started is now running into Gaspe Basin and in a short time the Matane Railway will also reach the town.

Dryden, Ont.—The Dryden Timber and Power Company, of Dryden, Ont., which is completing a sulphate plant and a paper mill for producing building and heavy wrapping papers, received a heavy setback recently when the power house and sluice gates were destroyed by fire, as stated in our contemporary paper. In the power house there were two turbine units of 950 hp. each connected direct to two, 750 kva generators. It was the intention to generate the current at 600 volts and distribute it through the various motors in the buildings. The concrete dam across the Wabigoon river is 140 feet long and 20 feet high, giving an available head of 45 feet. The location of the power house was at the foot of the lower falls, and the hydro-electric equipment had been installed. The loss by fire will reach $100,000 and it is said that it will fall on Harris & Harris, contractors, who had the work on the concrete dam and power house nearly completed. J. B. Beveridge is the manager of the Dryden Timber and Power Company. It was calculated that the work under construction at Dryden including the paper and pulp plant and the hydro-electrical development would involve an expenditure of nearly three-quarters of a million dollars.

THE ROAD EXHIBITION.

An exhibition of road materials, appliances, and machinery used for the construction, maintenance and improvements of roads, will be held at the Royal Horticultural Hall, Vincent Square, Victoria Street, London, S.W., in connection with the International Road Congress to be held in London in June, 1913.

It will be opened on Monday, June 23rd, by the Right Hon. Earl Beauchamp, first commissioner of H.M. office of works, president of the exhibition committee, and closed on Saturday, June 28th.

The exhibition is to be international and is open to all classes of machinery, apparatus, materials, models, drawings, plans and maps illustrative of road construction.

A piece of ground adjoining the Royal Horticultural Hall, will be completely roofed and walled in, and paved with wooden sleepers to form an exterior section of the exhibition, for the exhibiting of heavy machinery.

A room fitted up as a writing room will be available for the use of members of the congress and exhibitors, and at a marquee in the ground, tea will be served to all members and exhibitors on production of their membership cards.

All the leading firms engaged in the industry have decided to exhibit. They are representative of all branches of the industry, and include:

Tar-Macadams, Etc.—Messrs. Tarmac, Limited; Gas Light and Coke Co., Limited; Canadian Rubber Co., Limited; Roadamant, Limited; F. E. Bristowe & Co.; Anglo-American Petrol Products Co., Limited; Taroads, Limited; Rocmac, Limited; Roadite, Limited; Limmer Asphalt Co., Limited; Neuchatel Asphalt Co., Limited; Dussek Bitumen Co., Limited.

Machinery.—Messrs. J. & P. Hill, Limited; Barford & Perkins; T. Green & Sons; Aveling & Porter.

Quarries.—Messrs. Ellis & Everard; Enderby & Stoney; Stanton Granite Co., Limited; London Granite Co., Limited.

Publishers.—Messrs. Illiffe & Sons, Limited; John Hutchinson; Roads Improvement Association; Good Roads; Crompton & Co.

Mr. Maybury, county surveyor, of Kent, is honorary secretary of the exhibition committee.

It is expected that representatives from between two thousand and three thousand highway authorities from all parts of the world will attend the exhibition.

◆

HEAT AND POWER FROM SAWDUST.

An application has been made to the city of Vancouver by ten prominent saw-mill owners for a franchise to sell steam heat and electric light and power generated by burning saw-mill refuse. The application came immediately after the report of a committee of the City Council dealing with the smoke and saw-dust nuisance due to burning mill refuse in the city.

It is proposed to install plants for burning the refuse at each of the various mills, thus permitting a wide zone of distribution and enabling steam heat to be furnished at much lower pressure than from one central plant. The intention is to establish an auxiliary oil-burning apparatus at each mill for use in case of accident to the main plant and also whenever the supply of refuse runs low.

The problem of disposing of refuse without a loss has confronted mill owners for years and with coal selling at $7.50 a ton retail in Vancouver, it is thought that this scheme for utilizing it will prove successful. It is estimated that these mills have 114,000 cords of refuse and sawdust to burn each year. The approximate cost of installing each burner is placed at $30,000, and the annual operating cost at $5,000.

PERSONAL.

MR. C. B. HANDCOCK, construction engineer of the Manitoba Government Telephone Department, has resigned his position. It is reported that he will enter private business.

Capt. R. W. Hunt.

ROBERT W. HUNT, of Chicago, widely known as the head of the firm of Robert W. Hunt & Co., Limited, has been awarded the John Fritz medal for this year. This medal was founded in 1902 in honor of the veteran iron master whose name it bears "to commemorate notable scientific and industrial progress." Capt. Hunt was one of "John Fritz's boys." When about 20 years old he began work in the iron industry at Pottsville, Penn. Later he studied chemistry and became the chemist of the Cambria Co. He was at various times superintendent of steel works in Wyandotte, Mich., Johnstown, Penn., and Troy, N.Y. In 1888 he founded the firm of R. W. Hunt & Co., consulting engineers, inspectors, etc. He served in the Civil War from 1861 to 1865, rising from private to captain. The previous awards of this medal, besides the initial presentation to Mr. Fritz, have been to Lord Kelvin, George Westinghouse, Alexander Graham Bell, Thomas A. Edison, Charles T. Porter, Alfred Noble and Sir William White.

JOSEPH OWEN, late of the engineer's department, London County Council, England, was recently appointed assistant city engineer of Fort William, Ont. Mr. Owen was articled to Mr. T. Aird Murray, consulting engineer, Sheffield (now in practice at Toronto), for four years, and remained in the capacity of assistant for a further period of eighteen months. During this time he was engaged on extensive water supply, sewerage, and sewage disposal works for various municipalities, chiefly in the capacity of resident engineer. He then held for four years the position of assistant district engineer in the city engineer's department, Sheffield, where he left to take up the position of resident engineer on street railway and sewerage works for the Colchester Corporation, in which capacity he remained two and one-half years. Six and one-half years ago Mr. Owen joined the staff of the London County Council as assistant engineer, and obtained extensive experience on street and bridge improvements, and street railways on the conduit and overhead systems. Mr. Owen received his technical education at the Sheffield University, and is by examination an Associate Member of the Institution of Civil Engineers, a member of the Royal Sanitary Institute, and an Associate Member of the Institution of Municipal and County Engineers. Shortly prior to leaving England, Mr. Owen was elected to the Executive Committee of the latter institution, and about the same time was appointed lecturer in road construction, drainage, and sanitation at the Holloway Polytechnic Institute to prepare students for the Surveyor's Institute final examinations.

◆

RALIROAD EARNINGS.

The following are the railroad earnings for the week ended November 7th:—

	1911.	1912.	Increase or Decrease.
Canadian Pacific	$2,493,000	$2,938,000	+$445,000
Grand Trunk	956,818	1,061,984	+ 105,166
Canadian Northern	526,000	590,300	+ 64,300
Temiskaming & N. Ontario...	38,693	32,011	— 6,682

The following are the railroad earnings for the week ended November 14th:—

	1911.	1912.	Increase or Decrease.
Canadian Pacific	$2,486,000	$2,916,000	+$430,000
Grand Trunk	959,980	1,064,317	+ 104,337
Canadian Northern	504,000	609,500	+ 105,500
Temiskaming & N. Ontario...	35,794	28,864	— 6,930

For the quarter ending September 30th the receipts of the Guelph Junction Railway amounted to $12,072.70. The receipts for the other three quarters were $8,794.93, $6,510.36, and $8,840.30, making a grand total of $36,227.29 for the year.

The statement of earnings of the Canadian Northern Railway for October shows a gross increase of $322,300; net increase is $24,900. The four months' figures of the company, from the beginning of the new fiscal year on July 1st last to October 31st, make a more favorable showing in this respect, a gain of $1,096,400 in gross being accompanied by a gain of $218,100 in net.

The statement for the month follows:—

	1912.	1911.	Increase.
Gross earnings.............	$2,351,200	$2,028,900	$322,300
Expenses	1,645,900	1,348,500	297,400
Net earnings	705,300	680,400	24,900
Mileage in operation.......	4,297	3,731	566
	July 1 to date.	July 1 to date.	Increase.
Gross earnings	$7,598,200	$6,501,800	$1,096,400
Expenses	5,604,000	4,725,700	878,300
Net earnings	1,994,200	1,776,100	218,100
Mileage in operation........	4,297	3,717	580

VICTORIA'S BUILDERS ARE BUSY.

When the building permit was issued for Victoria's new high school, costing $416,750, the permits for structures aggregated $7,217,000 to date since the beginning of the current year.

The total building permits for 1911 amounted to $4,025,000.

With the permits for Oaklands and Quadra Street schools, costing nearly $100,000, to be issued next month, and the many private residences and stores now being planned, the grand total will be over eight millions, or twice the total of permits for last year. Oak Bay, Victoria's important residential suburb, has constructed over one million dollars' worth of building this year.

Greater Victoria's permits, including Oak Bay, Esquimalt and South Saanich, amount to nearly ten million dollars.

MEETINGS.

The annual meeting and dinner of the Manitoba branch of the Canadian Society of Civil Engineers were held Thursday evening, December 5th, at the Royal Alexandra, Winnipeg. At the business meeting, over which Col. Ruttan presided, J. T. Legrand, bridge engineer of the G.T.P., was elected chairman; E. Brydone Jack, secretary-treasurer, and W. A. Duff, D. A. Ross, W. L. Mackenzie and Frank Lee, executive committee. At the banquet, Prof. Featherstonhaugh presided in the absence of Mr. Hesketh. This branch has now about 70 members.

The ninth annual convention of the American Association of Manufacturers of Sand-lime Products was held in the King Edward Hotel, Toronto, on December 4th. The convention is held for the first time in Canada, and was largely attended by the foremost manufacturers from the United States and the Dominion. The meetings were presided over by President S. O. Goho, of Harrisburg, and Secretary W. E. Plummer, jr., of Buffalo.

A meeting of the mechanical section of the Canadian Society of Civil Engineers was held in the rooms of the Montreal Club of this society on December 5th last. Mr. Russel S. Smart, A. M. Can. Soc. C.E., entertained those attending by an address on "Patent Law from an Engineer's Standpoint."

COMING MEETINGS.

NATIONAL ASSOCIATION OF CEMENT USERS.—December 12th to 18th. Annual Convention, Pittsburgh, Pa. President R. L. Humphrey, Harrison Building, Philadelphia, Pa.

AMERICAN WOOD PRESERVERS' ASSOCIATION.—Ninth Annual Convention will be held at Chicago Jan. 21-23. 1913. Secy-Treasurer, F. J. Angier. Mount Royal Station, B. & O. R. R., Baltimore, Md.

AMERICAN INSTITUTE OF CONSULTING ENGINEERS.—Annual Meeting, January 14th, 1912, will be held at The Engineers Club, 32 West Fortieth Street, New York, N.Y. Secretary, Eugene W. Stern, 103 Park Avenue, New York.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings,

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh B. Fergusson 911 Rogers Building, Vancouver, B.C. Headquarters: McG University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P. O. Box 1290

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack. Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose. Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. B. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr, G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bioor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W H Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

Place of Work.	Tenders Close.	Issue of.	Page.
Kamloops, B.C., power house equipment	Dec. 19.	Dec. 5.	65

Winnipeg, Man., turbines and governors	Dec. 16.	Nov. 28.	66

TENDERS.

Aylmer, Ont.—Sealed tenders addressed to R. C. Desrochers, Secretary Department of Public Works, Ottawa and endorsed "Tender for public building, Aylmer, Ontario," will be received at the above office until 4 p.m., on Monday, December 30th, 1912, for the construction of a public building at the place mentioned. Plans, specifications and form of contract can be seen and forms of tender obtained at the post office, Lonodon, Ont., at the Post Office, Aylmer, Ontario, and at the Department of Public Works, Ottawa. Ontario.

Fort William, Ontario.—A. L. Farquharson, construction superintendent, is open to receive tenders for the following street railway material:—Steel, angle bars, spikes, bolts, cedar poles, ties, trolley wire, overhead material. Form of tender and particulars can be had at the office of the above.

Hamilton, Ont.—R. C. Desrochers, Secretary Department of Public Works, Ottawa, will receive sealed tenders marketd "Tenders for Hamilton Harbor Improvements," up to 4 p.m. Monday, December 30th, 1912. (See ad. in The Canadian Engineer.)

Halifax, N.S.—C. W. West, Architectural Engineer, 44 Granville Street, Halifax, and 133 Waterloo Street, St. John, also 42 Maywood Street, Boston, Mass., is the designer of a new building to be erected for the Halifax Herald. Tenders are invited, to be received by Monday, December 23rd, for plumbing, engine and direct connected dynamo, steam boiler and steam heating. Plans and specifications may be seen at any of the above addresses, or at the office of the general contractors, Messrs. Thompson and Theakston at the work in Halifax.

Kelowna, B.C.—Sealed tenders will be received by G. H. Dunn, Secretary, Kelowna Board of School Trustees, up to 5 p.m. of the third day of January, 1913, for the erection of a ten-room school at Kelowna, B.C., building to be of brick and to be completed not later than August 1st, 1913.

The plans, specifications, and all necessary information may be had from the Secretary of the School Board, Kelowna, B.C., or G. E. Nobles, architect, Lethbridge, Alta.

Orillia, Ont.—Sealed tenders, marked on envelope "Tender for construction of new drill hall, Orillia, Ont.," and addressed to the Director of Contracts, Department of Militia and Defence, Ottawa, will be received until noon, December 19th, 1912, for the construction of a new drill hall at Orillia, Ontario. Specifications may be seen and full particulars obtained at the office of the General Officer Commanding 2nd Division, Toronto, Ontario, the Town Clerk, Orillia, Ont., and the Director of Engineer Services, Headquarters, Ottawa.

Ottawa, Ont.—J. D. McLean, Asst. Deputy and Secretary Department of Indian Affairs, Ottawa, will receive sealed tenders endorsed "Tenders for Indian Supplies," up to noon, Tuesday, January 7th, 1913, for the delivery of Indian supplies during the fiscal year ending March 31st, 1914. Forms of tenders and all particulars may be obtained from the above at Ottawa.

Ottawa, Ont.—Sealed tenders addressed to R. C. Desrochers, Secretary, Department Public Works, Ottawa, and endorsed "Tender for Re-Erection and Completion of a Lobnitz Rock Breaker," will be received at this office until 4.00 p.m. on Monday, December 23, 1912, for the re-erection and completion of a Lobnitz rock breaker.

Plans, specification and form of contract can be seen and forms of tender obtained at this department and at the offices of T. H. Schwitzer, Esq., mech. superintendent, Birks Building, Ottawa, Ont., and C. E. W. Dodwell, Esq., district engineer, Halifax, N.S.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to ten per cent. of the amount of the tender.

Point Grey, B.C.—Separate sealed tenders for valves, special castings, and hydrants, will be received by C. H. Heighway, Clerk of the Municipal Council of Point Grey, B.C., will be received up to January 6th, 1913. (See ad. in The Canadian Engineer.)

Sarcee Indian Reserve.—J. D. McLean, Asst. Deputy and Secretary, Department of Indian Affairs, Ottawa, will receive sealed tenders up to January 3rd, 1913, for the erection of two school buildings at this point.

Plans and specifications may be seen at the Dominion Land Offices at Edmonton, Calgary, Medicine Hat, and Lethbridge, at the Indian Office, Winnipeg, and at the office of the Indian agent on the Sarcee Reserve.

Each tender must be for both buildings complete and must be accompanied by an accepted cheque on a chartered bank for ten per cent. of the amount of the tender, made payable to the order of the above.

St. John, N.B.—Sealed tenders addressed to R. C. Desrochers, Secretary Department of Public Works, Ottawa, and endorsed "Tender for post office building, St. John, N.B.," will be received at the above office until 4 p.m. on Monday, December 30th, 1912, for the erection of a post office building at St. John, N.B. Plans, specifications and form of contract can be seen and forms of tender obtained at this Department, on application to Mr. G. B. Fairweather, Archt., 84 German Street, St. John, N.B., and at the office of Mr. R. L. Deschamps, 103 St. Francois Xavier Street, Montreal.

Toronto, Ont.—Tenders will be received by registered post by the Chairman of the Board of Control, City Hall, Toronto, for the construction of sewers as per details in the ad. in The Canadian Engineer. The closing date for the above is December 17th, 1912.

Vancouver, B.C.—Sealed tenders addressed to the Secretary of the Y.M.C.A., Cambie Street, Vancouver, will be received up to noon of December 23rd next for the erection of a new association building on Georgia Street. Separate and bulk tenders are invited for the following trades,—

1. Excavation and concrete.
2. Structural steel.
3. Brick work and terra cotta setting.
4. Terra cotta.
5. Carpentering.
6. Plumbing.
7. Plastering.
8. Marble and tile work.
9. Roofing and sheet metal work.
10. Elevators.
11. Ornamental iron.
12. Painting and glazing.
13. Linoleum.

Plans and specifications may be had upon application to the architect. H. S. Griffith, Dominion Trust Building, Vancouver.

Ville-Marie, P.Q.—R. C. Desrochers, Secretary Department of Public Works, Ottawa, will receive sealed tenders endorsed "Tenders for Wharf at Ville-Marie, Que.," up to 4 p.m., January 7th, 1913, for the construction of a wharf at this point.

Plans, specifications and form of contract can be seen and forms of tender obtained at this Department, and at the offices of J. L. Michaud, Esq., District Engineer, Merchants Bank Building, Montreal; and on application to the Postmasters at Ville-Marie, Que.; Haileybury, Ont., and at North Bay, Ont.

Each tender must be accompanied by an accepted cheque on a chartered bank payable to the order of the Honorable the Minister of Public Works, equal to ten per cent. (10 p.c.) of the amount of the tender.

Victoria, B.C.—Sealed tenders, superscribed "Tender for Motor Launches," will be received by the Honorable the Minister of Public Works up to and including 23rd day of December, 1912, for the construction of two 55-foot and four 36-foot motor launches.

Plans, specifications, contract, and forms of tender may be seen at the offices of the Government agents at Vancouver and New Westminster, and the Department of Public Works, Victoria.

Victoria, B.C.—Sealed tenders, superscribed "Tender for Motor Launches," will be received by the Honorable the Minister of Public Works up to 12 o'clock noon of Monday, 23rd day of December, 1912, for the construction of two 25-foot motor launches.

Intending bidders will give full description of the hull, engine, etc.

Delivery. One launch at Arrowhead; the other at Nelson.

Each proposal must be accompanied by an accepted bank cheque, payable to the Honorable the Minister of Public Works, for a sum equivalent to ten per cent. of the amount of the tender.

Forms of tender can be obtained from the Government agents at Vancouver, New Westminster, Revelstoke, and Nelson, and the Department of Public Works, Victoria.

Winnipeg, Man.—Tenders will be received by The Elm Park Company, Limited, for the construction of the steel superstructure of a bridge across the Red River from a point near Jubilee Avenue to Riverdale Avenue, in Elm Park. Plans, specifications and conditions may be seen at the office of Prof. E. Brydone-Jack, 53 Canada Life Building, corner of Portage and Main, Winnipeg, on and after Monday, December 9th. All tenders must be delivered to the company on or before Tuesday, December 17th, accompanied by marked cheque for 10 per cent. of the amount of the tender.

CONTRACTS AWARDED

Brantford, Ont.—It is reported that Messrs. P. H. Seward and Sons have received the contract for all concrete work on the Lake Erie and Northern Railway. The price is reported to be $150,000.

Esquimalt, B.C.—The Esquimalt council has awarded its contract for the lighting of a section of the municipality [illegible] B.C.E.R. and work upon this important civic work will be started at once.

Edmonton, Alta.—The contract for a fourth bridge across the Saskatchewan, to cross at the foot of Fifth Street, has been awarded by the city to the Lyall-Mitchell Company for $97,898.

Fredericton, N.B.—The contract for the sub-structure of the new bridge over the reversible falls at St. John has been awarded to Joseph McVay and Son. The work is to be completed by December 1st, 1913 and the cost will be approximately $50,000.

Grand Forks, B.C.—Contracts to be awarded in the near future by the Hidden Creek Mine management will aggregate about $400,000. About twelve machinery firms will share the order.

Vancouver, B.C.—The tenders submitted for the erection of a police headquarters are so much higher than anticipated that the cheques have been returned to the senders and the matter dropped for the present.

Victoria, B.C.—The Canadian General Electric Company have been awarded a contract for the supply of $3,218 worth of electric cable as required by the fire department.

Victoria, B.C.—The Gamewall Fire Alarm Company have been awarded a contract to supply four large fire gongs and seven relay boxes to the municipal fire department at a cost of $450.

RAILWAYS—STEAM AND ELECTRIC.

Ottawa, Ont.—The Canadian Northern Railway will apply to the Federal Parliament for a time extension on the date for the completion of the following lines:—

Washago to Kincardine.
Arnprior to Gananoque.
Pembroke to Cobourg or Port Hope.
Frenchman's Bay, northwesterly to Owen Sound.
Niagara River to Goderich.
Hawkesbury to a point in the County of Leeds or Lanark.
Parry Sound to North Bay.

Province of New Brunswick.—The Provincial Government will extend the time for the completion of Gibson and Minto Railway for about seven months; it is not likely that much construction work on the line will be done during the coming winter.

Ottawa, Ont.—The Canadian Northern Railway will apply to the Federal Parliament for an act authorizing the construction of the following lines:—

An extension of the Berlin, line, through Guelph, Acton and Brampton to Toronto, southwesterly to Stratford and St. Marys, with a branch to Woodstock.
Sarnia to Chatham.
Orillia to Goderich via Owen Sound, or with a branch to Owen Sound.

Northern Canada.—There is some publicity being given to a scheme called the Porcupine Rand Belt Electric Railway Company, with Mr. C. H. Fullerton as engineer of construction. The first seventy miles of the line are to be surveyed during the coming winter, but the entire plan calls for an electric railroad, with lines stretching from Winnipeg to Quebec and with seven points of contact with the great steam roads of the country. Mr. F. Adalia, Toronto, is first vice-president of the company.

Vancouver, B.C.—The Board of Railway Commissioners, following the hearing of complaints regarding inadequacy of depot facilities, has ordered the British Columbia Electric Railway Company to file statements regarding the intention of that corporation in the erection of terminal for the Lulu Island Line.

Western Canada.—One or two prominent Western Canada railway men have stated that winter work on the Grand Trunk Pacific lines will not be practical.

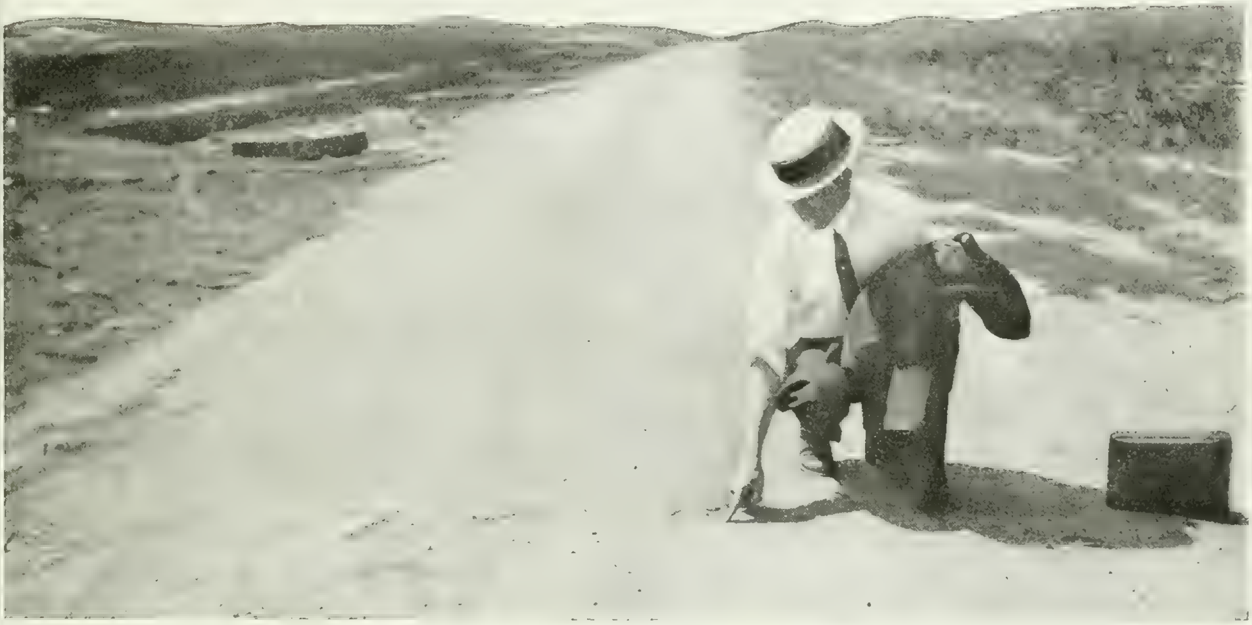
LIGHT, HEAT AND POWER

Clinton, Ont.—Clinton town council have decided to submit a by-law at the municipal election to raise $33,000 to purchase the Clinton electric light plant, erect a transformer station, and accept power from the Hydro-Electric Commission at $39 per horse-power.

New Westminster, B.C.—The British Columbia Electric Railway Company are planning to remodel their electrical distribution system on all existing lines in the Fraser Valley

Tarvia

Preserves Roads
Prevents Dust~



Country Club Road, Greenville, S.C. Built with Tarvia X.

What the Government Found Out About Tarvia

THE Office of Good Roads, U.S. Department of Agriculture, built an experimental road at the country club at Greenville, S.C., in 1909, following very closely our specifications for two-coat penetration work, using "Tarvia X."

After two years the above photograph of the road was taken at a point where it adjoins a stretch of plain macadam. The intention of the Department was to find out just how much difference the Tarvia treatment made.

The picture tells the story. The plain macadam in the foreground is *worn out*. The tarviated surface is in *perfect condition*, and the difference is so great that a clear division line is seen in the above photograph.

This is a typical instance of the success of Tarvia as a road binder. A tarviated road is automobile proof, waterproof, dustless and mudless. It is so much cheaper to maintain that the cost of using Tarvia in the construction is more than compensated for.

Tarvia is made in three grades:

"Tarvia X" for use in constructing roads and pavements.

"Tarvia A" for hot surface applications.

"Tarvia B" (applied cold) for dust prevention and road preservation.

Tarvia Booklet mailed free to anyone interested. Address our nearest office.

THE PATERSON MANUFACTURING COMPANY, LIMITED
MONTREAL TORONTO WINNIPEG VANCOUVER

THE CARRITTE-PATERSON MANUFACTURING CO., LIMITED
ST. JOHN, N.B. HALIFAX, N.S.

and the lower mainland. If these plans are put into action it will involve the expenditure of vast sums of money.

Victoria, B.C.—The Pacific Great Eastern Development Company, which is a subsidiary corporation controlled by the Pacific Great Eastern Railway, is applying to the government for a license to take and use for power purposes 2,000 cubic feet of water per second out of Cheakamus River, a tributary of the Squamish River, in the Howe Sound district. The water will be diverted at a point two miles below North Creek fork.

Winnipeg, Man.—The operation of the civic electrical plant, as shown by a recent report, gives ample ground for hope that 3 cent rate may be established in this city during the next few months. The profit for November was $10,000.

Winnipeg, Man.—Prof. L. A. Herdt has submitted to the board of control his recommendation for the erection of a second transmission line to Point du Bois, adding two units to the plant there and enlarging the facilities at the McPhillips Street sub-station. The whole project would cost $700,000 and would protect the city against all trouble that might occur.

◆

GARBAGE, SEWAGE AND WATER.

Edmunds Burnaby, B.C.—Engineer MacDonald, of the waterworks department of this municipality, has submitted a report to the council wherein he states that $250,000 is the sum required to put the waterworks in satisfactory operating conditions. Pipe, hydrants and an additional pumping unit are the chief items in the report.

Lethbridge, Alta.—The recently installed sewage disposal plant was placed in operation a few days ago.

◆

BUILDINGS AND INDUSTRIAL WORKS

Brandon, Man.—The Canadian Northern Railway will erect a $10,000 freight shed at this point during the coming spring.

Brantford, Ont.—The plans of a new government building to be erected here have been made public; they show a structure of stone, with a clock tower in one corner, 3 stories in height. Mr. W. F. Cockshutt, M.P., is interested in the matter.

Bridgeburg, Ont.—The ratepayers and council are seriously considering the erection of a new town hall.

Fredericton, N.B.—Messrs. D. Fraser and Sons, will have the Victoria Mills rebuilt and enlarged, Mr. W. H. Montague, of Hartford, Conn., U.S.A., will prepare plans for this work.

Galt, Ont.—Mr. W. R. Osborne, Ainslie Street, is considering the matter of erecting a business block; the design that he contemplates calls for red brick construction two stories in height.

Halifax, N.S.—The council of this municipality have selected a plan for a new market prepared by Sydney P. Dumaresq.

Hamilton, Ont.—Messrs. Dixon Bros. have commenced construction work on a new warehouse to be of brick and concrete. It will cost about $20,000. Mr. W. A. Edwards is the architect.

Lethbridge, Alta.—Mr. P. J. McInenly is interesting a number of local business men in a proposition calling for the erection of a covered rink to be used for exhibition hockey games.

Lloydminster, Alta.—The ratepayers of this municipality will erect a new town hall to replace the one recently destroyed by fire. The building is to cost $5,000 or $6,000.

Medicine Hat, Alta.—Mr. E. C. Metzner has purchased a block of property on Toronto Street, and a report states that a six story hotel will be erected.

Niagara Falls, Ont.—The congregation of the First Baptist Church will erect a new church on Simcoe Street. Rev. O. C. Gray, Pastor.

New Westminster, B.C.—Publicity Commissioner C. H. W. Stuart states that there is a probability of a $10,000,000 steel plant locating in this city.

Ottawa, Ont.—A number of Roman Catholic residents in the section of the city known as the Glebe are working for the erection of a new church.

Port Arthur, Ontario.—The Canadian Northern Railway, according to report will erect a new cement dock and a coal shed, together with other improvements. It is planned to have this work well under way by the summer of 1913.

Port Arthur, Ont.—The management of the Soo Falls Brewing Company will erect a brewing plant in the south end of the city.

Sault Ste. Marie, Ont.—The Canadian Northern Railway have placed an order with the steel mills at this point for 15,000 tons of rails to be delivered at Kamloops early in January.

South Saanich, B.C.—The education officials of this municipality will erect two school buildings in the immediate future at a cost of $12,000 and will take steps for the erection of a third building at an early date. This place is not far from Victoria. Captain H. J. Rous-Cullin is architect to the school board.

Vancouver, B.C.—Messrs. A. Grossman and Son have purchased a site and, according to report, will erect a ten-story block.

Vancouver, B.C.—The municipal Park Commissioners will consult an architect on the matter of providing better quarters for bathers at the various civic bathing beaches.

Vancouver, B.C.—Officials of the American Can Company are considering the erection of a branch plant in this city. Mr. F. P. Kendall, of Portland, Or., is western manager of this company.

Victoria, B.C.—The new observatory, to be erected by the federal authorities, will be located on Gonzales Hill, 210 feet above the sea level. This structure is to cost about $20,000.

Winnipeg, Man.—The management of the Dominion Trust Company have recently purchased a site and propose the erection of a large office building.

◆

BRIDGES, ROADS AND PAVEMENTS.

Assiniboine River, Man.—The large wooden trestle bridge of the Canadian Northern Railroad collapsed and fell into the river below. The accident happened on the morning of December 3rd and it is thought that the cause of the collapse may be traced to a Grand Trunk Pacific car that became derailed while crossing and that the vibrations arising from this caused the bridge to loosen some important brace. The car was one of a freight train.

Ottawa, Ont.—The board of railway commissioners has authorized the C.P.R. to construct a bridge to carry its proposed tracks across the Ottawa waterworks aqueduct.

Sault Ste. Marie, Ont.—The bridge over the Michipicoten River, on the Algoma Central Railway system, was completed recently by Geo. Fitzgerald, of Ottawa, just one month ahead of the time called for in the contract. The bridge has cost $100,000, and is 300 feet long.

Vancouver, B.C.—Among the list of by-laws to be submitted to the ratepayers is an item of $100,000 for proposed alterations to the Georgia-Harris bridge.

Vancouver, B.C.—The Board of Railway Commissioners have ordered that the Canadian Pacific Railway construct electrically operated gates at the Columbia Avenue crossing of their tracks. These gates will automatically close when a train approaches and will shut off the passage of vehicles and pedestrians until danger has passed.

Victoria, B.C.—According to an announcement in a recent issue of the British Columbia Gazette, the provincial parliament will construct a highway to be known as the Victoria-Campbell River Trunk Road, this road is to have a width of forty feet and will be about nineteen and a half miles in length. It will commence on the left bank of a branch of the Cowichan River, in the centre of the Clem-Clem-a-letz bridge and runs to a point on the district line between the districts of Oyster and Chemainus.

Victoria, B.C.—The management of the Worswick Paving Company are about to make several improvements to their plant which will cost about $20,000 and enable this company to carry out street paving contracts to a better advantage. The improvements consist of a rock crushing plant and an enlargement to the premises that will give a capacity of 100 tons per day of street paving material.

WETTLAUFER MIXERS

are carried in stock in all sizes; if you need a mixer quickly to finish that work before the really cold weather, telephone or telegraph us, and we will place it on your work immediately.

We have manufactured concrete mixers and concrete machinery of all kinds for many years; also previously had taken contracts for concrete work of all kinds, and have had the actual experience of just what a concrete mixer should do. Wettlaufer Mixers are perfect to-day through the help of the hundreds of contractors who purchased the Wettlaufer Mixers in past years. We have gone personally to them and watched these machines working on all classes of work, asked the contractors their opinions, and so have evolved the present perfect mixer.

If you expect ever to purchase a concrete mixer, write now for our catalogue. Compare the simplicity of our mixer with other makes. The main points in favor of our mixer are its thoroughness, simplicity and durability. The Wettlaufer Mixer is of the heart-shaped drum type; this means quick and positive mixing, also the saving of power

HENRY HOPE AND SONS FACTORY FOR CANADA

Attracted by the number of factories and other buildings being erected in Canada for which metal sash could be used advantageously, Henry Hope & Sons, Limited, of Birmingham, England, have decided to build a Canadian factory. Peterboro, Ontario, has offered a free site and exemption from taxes, excepting educational and local improvement taxes, and if the by-law making this grant is approved of by the electors of Peterboro next January 1st, a factory will be established there.

The site is bounded by Park, Romaine and Monaghan Streets, and is about 2,000 feet by 220 feet. It will be served by both the Grand Trunk and C.P.R. The first building will be a machine shop about 100 feet by 200 feet. It is intended to erect a model plant, with employees' lunch and rest rooms, recreation grounds, etc. About fifty men will be employed at the beginning. The plant will be constructed with the Hope sash and with saw tooth roof construction, with Hope's patent roof glazing. It is intended that the plant be a model daylight factory. Sproatt & Rolph, of Toronto, will be the architects. One of their staff will visit the English factory, of which the Canadian factory will be a duplicate, to get data for preparing plans.

The capital for the Canadian company, which will be called Henry Hope & Sons, Limited, of Canada, has been all subscribed. H. D. Hope, President of the English company, is also President of the Canadian company. A. L. Young, of Toronto, is Vice-President, Secretary-Treasurer and Manager; and David McGill, of Montreal, is a director.

Mr. A. L. Young.

Henry Hope & Sons, Limited, was established in 1818. They ship all over the world, but have been interested in Canada for only about five years. The business in Canada has grown to such proportions, and also that in the United States, which territory they started to invade about three years ago, that it was deemed necessary to have a factory on this side of the water.

In June, 1911, Mr. A. L. Young, who had been for twenty-seven years connected with The Aikenhead Hardware Limited, of Toronto, and who is still Vice-President of that concern, decided to give his entire attention to pushing the sale of Hope sash in Canada, and opened an office at 45 King Street West. Among the more important contracts executed in Canada have been The Bank of Toronto new head office building; McGill University; Union Bank Building, Toronto; Burwash Hall and the library of Victoria University; Saskatchewan University; four buildings for the Consumers' Gas Company; Copp, Clark Co.'s new warehouse; Gage's warehouse; Samuel Benjamin's new warehouse; Rolph & Clark's new factory; B.C. Sugar Refinery; B.C. power house; [illegible] pumping station and power house; power house and transformer station for the Sydney Electric Power Company of Trenton, Ontario, etc.

It is intended, at the start, to manufacture only the steel sash and patent roof glazing at the Peterboro plant, but the firm of Henry Hope & Sons, Limited, also manufacture a very high grade of gun metal sash. This sash is actually manufactured of the same metal that is used for the English battleship guns, and is extremely tough and durable.

Steel sash for factory and mill buildings, power houses, pumping stations, or wherever light, ventilation or fireproof construction is valued, will give 25 to 30% more light to the same size openings than wood sash and is very little more expensive.

◆

FIRES.

Bobcaygeon, Ont.—The power plant of the Bobcaygeon municipality was destroyed by fire with a loss of $5,000. The hydro-electric engineers have been requested to furnish a solution to the problem of temporary lighting.

◆

CURRENT NEWS.

Berlin, Ont.—The Berlin water commission has just completed the erection of the largest water tower in America, which they will use for the first time about Christmas. It is capable of holding 2,500 tons of water. It has a capacity of a half million imperial gallons and cost $23,000.

Fredericton, N.B.—The trustees of the Victoria Public Hospital are considering the purchase of an x-ray machine and if they decide on such a move, will expend $1,500 on such an instrument.

Medicine Hat, Alta.—December 27th next is the date set apart for the vote of the ratepayers on eight by-laws. The money by-laws consist of the following: $65,000 for purchase of land for park purposes; $15,000 for purchase of land for widening streets; $68,000 for the purchase of land for industrial purposes.

Montreal, Que.—Judge Lafontaine recently awarded a workman a pension of $100 per year for loss of a foot that was amputated through being frost bitten while at work for the company with which he was employed.

New Westminster, B.C.—Out of eighteen firms who applied for specifications for work on New Westminster's harbor scheme, but one tender was received. The Westminster Dredging and Construction Company put in a bid of about $600,000 for the work. This was the extreme limit placed for the work. The tenders were called for chiefly for the purpose of ascertaining the advisability of doing the work by day labor.

St. Thomas, Ont.—The ratepayers endorsed a by-law giving certain inducements to the Wright Shoe Company to locate a branch plant at this point.

Welland, Ont.—The total of the building permits issued in this municipality for the past ten months, amount to $458,571.

◆

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

18153—November 20—Postponing to and including December 31st, 1912, the effective date of the Wabash R.R. Co.'s Supplement No. 1 C.R.C. No. 635, and Item No. 10 in C.R.C. No. 654.

18154—November 2[illegible]—Authorizing C.L.O. and W. (C.P.R.) to construct road diversion to connect with road allowance between Cons. 1 and 2, Tp. Hope, Co. Durham, Ont.; and construct road diversion at mileage 130.21 from Glen Tay.

18155—November 28—Authorizing C.P.R. to construct spur for the Stewart Sheaf Loader Company, Limited, Winnipeg, Man.

18156—November 28—Recommending the Indenture of Lease, dated October 2nd, 1912, made between the Quebec Central Railway and the C.P.R. to the Governor in Council for sanction.

18157—November 29—Authorizing C.P.R. to open for traffic its Lauder Extension from Tilson, mileage 28.7 to Alida, mileage 54.72.

18158—November 29—Authorizing C.P.R. to open for traffic the following portions of new second track:—Crete to Sudbury, mileages 75.7 to 78.9, Cartier Subdivision; Devon, mileage [illegible], Chapleau Subdivision, to Fisher, mileage 6.9, White River Subdivision; Depew to White River, mileages [illegible], White River Subdivision; Heron Bay, to Peninsula, mileages 55.5 to 64.2, Schreiber Subdivision; Fire Hill to Ruby, mileages 55.0 to 59.4, [illegible] to [illegible], mileages [illegible] to [illegible], Nipigon Subdivision.

18159—November 28—Authorizing C.P.R. to construct bridge to carry proposed additional tracks across Ottawa Waterworks Aqueduct, Ottawa, Ontario.

18160—November 29—Authorizing C.P.R. to construct spur for L.A.F. and F. G. Crepeau, on Lot Cadastral No. [illegible], Parish of St. Henri, de Mascouche, Co. L'Assomption, Que.

18161—November 29—Approving revised location C.P.R. from mileage [illegible], Sec. [illegible], Tp. [illegible], R. [illegible], W. 4 M., for a distance of [illegible] miles, to a point in Sec. [illegible], Tp. [illegible], R. 15, W. 4 M., Alberta.

18162—November 29—Authorizing C.P.R. to divert highway between S.E. ¼, Sec. 4, Tp. 40, R. 10, W. 3 M. and N.E. ¼, Sec. 33, Tp. 39, R. 10, W. 3 M., Saskatchewan.

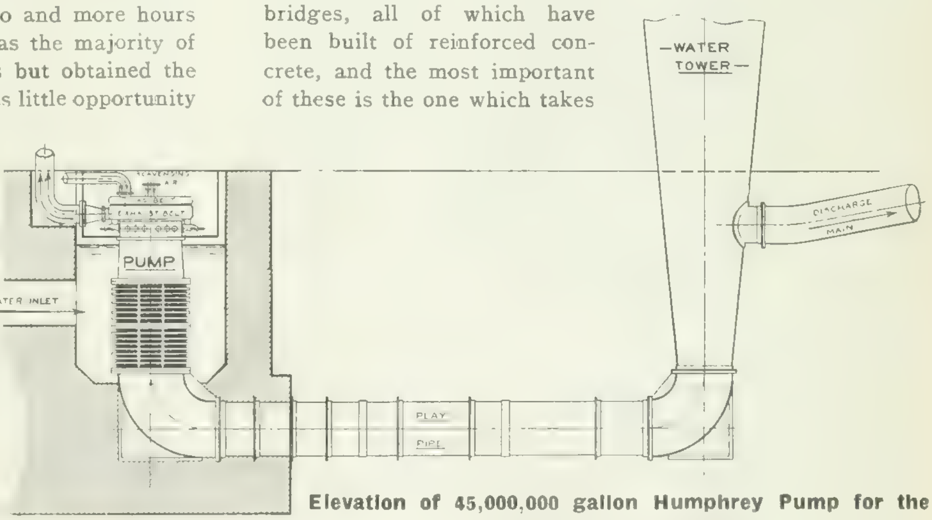
An Engineering Weekly

WATER SUPPLY FOR LONDON—LARGE HUMPHREY PUMPS.

A few years ago the water supply of Greater London was in the hands of various companies scattered throughout the suburbs; consequently, with so many suppliers, which varied in size and influence, and of course monopolized the business in their own particular districts, it is not surprising that the service for such an enormous collection of humanity, as is contained in the London area, left much to be desired. In many instances the companies did not increase the capacity of their plant in proportion to the growth of population, and during the prevalence of drought it was not unusual for the supply to be subject to great irregularity. In one particular area, in the north-east of the metropolis, serious inconvenience and danger to health were caused during dry summers by the supply being so inadequate that the water was occasionally cut off at the mains for 20 and more hours per day for many days in succession, and as the majority of the houses were not provided with cisterns but obtained the supply from the service pipe direct, there was little opportunity for the inhabitants to store any useful quantity. It was not uncommon to find that while conditions prevailed in some districts which closely resembled a water famine, only a short distance away—perhaps in the next street—plenty of water was available owing to the supply having been controlled by another authority who were placed in more fortunate circumstances.

In order to overcome these unsatisfactory conditions the various companies were merged into the Metropolitan Water Board at a cost of about £47,000,000 ($235,000,000), and it may be said that since then vast improvements have taken place in the service, and that, at least in comparison with the former conditions, the supply is now as nearly perfect in its regularity as it could be. However, to avoid a recurrence of the old difficulties the Board immediately started on the reorganization of the various plants and on the construction of several large reservoirs to form additions to those that then existed.



Elevation of 45,000,000 gallon Humphrey Pump for the City of London, England.

The largest of these reservoirs, which is situated at Chingford in the north-east of London, was begun in April, 1909, and is now practically completed. It is anticipated that it will be opened by the King towards the end of the year. The capacity of the reservoir is 3,000,000,000 gallons, as against 2,468,000,000 gallons, which was the total capacity of 12 reservoirs formerly belonging to the East London Water Company who supplied the district. The area of the new reservoir is 416 acres. It has 4½ miles of puddle core embankment, it is 1¾ miles long, about one-third of a mile wide at its narrowest part, and ¾ mile at its broadest. It has been constructed in the valley of the River Lee, a tributary to the Thames, and to make room for it the Lee has been diverted from its course for a length of three miles by a channel 55 ft. wide and 5 ft. deep, with side walls of concrete faced with Kentish rag stone and surmounted by a coping of concrete blocks. A smaller channel 3½ miles long has been provided to divert the contaminated water from the hill side and to discharge it into the old river channel clear of the site of the reservoir. The work has necessitated the construction of several bridges, all of which have been built of reinforced concrete, and the most important of these is the one which takes the public road over the river diversion. This structure is built on the skew and has three spans of 27½ ft. with 5 ft. rise and a width of 40 ft. between parapet walls. The embankment of the reservoir has been formed of material excavated from within its area, and it contains 2,000,000 cu. yds. of earthwork and 253,000 cu. yds. of puddle. The top of the embankment is 15 ft. wide, and is 5 ft. above top water. The outer slope is 2½ to 1, and the inner slope is 3 to 1 for a portion which is lined with concrete, beyond which the slope is 4 to 1. The core is 5 ft. wide at the top—three ft. below bank level—and is battered on both sides for a depth of 23 ft. 6 in., at which point it is 9 ft. wide. This thickness continues for 2½ ft. below the ground surface, and then it batters in with slopes of 1 to 1 on both sides to a thickness of 6 ft. until the London clay is reached. It then slopes in again with ½ to 1 slopes for a depth of 3 ft., forming a key into the clay.

The most interesting feature of the whole work is the installation of some very large Humphrey explosion pumps to deliver the water from the River Lee above the diversion into the reservoir. There will be five of these pumps, and in order to take advantage of sudden floods they will have a total capacity of 180,000,000 gallons of water per day, a quantity that is equal to two-thirds of the daily water supply of London. Four of the pumps will each be capable of delivering 40,000,000 gallons of water per day, while the fifth will have a capacity of 20,000,000 gallons. In normal circumstances the small pump only will be used. The fuel for the pumps will be producer gas, and they will, of course, work on the internal combustion principle with the explosion in direct contact with the water to be lifted. In the larger pumps the combustion chambers and valve boxes are both 7 ft. in diameter with a 6 ft. play-pipe. The vertical towers at the other end of the pipe are in the shape of an inverted cone and are 15 ft. in diameter at the top which is 58 ft. from the bottom of the tower. On each explosion 10 tons of water will be forced into the tower, from which it will flow into the reservoir by gravity. With anthracite at 22s. a ton delivered the guaranteed cost is 0.0196 penny per 1,000 gallons delivered into the reservoir, and the guaranteed consumption is 1.1 lb. of coal per actual water h.p. hour. It is expected that in practice the actual cost will be still lower, or 0.016 penny per 1,000 gallons.

This type of pump is of comparatively recent introduction, and in designing it, the inventor, Mr. H. A. Humphrey, has stated that his object was to produce a pump of great simplicity and strength in which the explosive force is exerted directly upon the water, and in which no fly-wheel, solid piston, connecting rod, crank, bearings, or glands of any kind are required. (See The Canadian Engineer of December 21st, 1911). When the explosion occurs there is a full bore passage from the combustion chamber to the final outlet; some of the water pumped to a high level by the energy of the explosion is allowed to return again in order to compress a fresh combustible charge. When sudden changes of velocity occur in masses of a heavy and incompressible liquid such as water, difficulty is found in controlling the movement of the liquid; all such difficulties, however, are removed in this pump by allowing the movements of liquid to control the pump and by causing the mass of liquid moved to be sufficiently large so that the velocities are never excessive. The mass of water forms a pendulum which swings between the high and low level, and, by its movement alone, serves to draw in fresh water, to exhaust the burnt products, to draw in a fresh combustible charge, and to compress the charge previous to ignition. With the movements of the liquid quite unrestrained by any of the usual mechanical appliances the result is a pump which works with freedom from shock and noise and requires very few working parts. The arrangement consists essentially of a horizontal pipe connected by two bends at its ends with a vertical closed combustion chamber and the open water tower. The parts thus connected are nearly full of water forming a heavy mass or column of liquid which is made to oscillate under the action of the explosion. This oscillation is free and occurs in such a manner that the movement of the water causes the intake of a fresh combustible mixture, the compression of the mixture, the explosion and expansion which give the power stroke, and the exhaust. There are thus four primary movements of the water during each cycle, two being from the combustion chamber towards the tower and two in the opposite direction. The success of the arrangement is due to the use of the momentum acquired by the moving mass of water, for it is this momentum which enables the outward swing of the water under the action of the explosion to continue after the expansive force of the gases has finished and thus to draw in scavenging air and to cause the intake of fresh water from the low level, or supply, during the first outward stroke. On the first inward stroke which takes place under the head to which the water has been lifted, the column of water is allowed to acquire velocity and momentum while merely exhausting the burnt gases, and then the momentum is utilized to compress a cushion scavenging air imprisoned in the top of the combustion chamber above the exhaust valves. Energy is thus stored in the compressed cushion, and the cushion expands giving the second outward stroke and also the momentum which is relied on to carry the water column far enough to draw in behind it a fresh mixture of gas and air. The second return stroke takes place, and the explosive mixture is compressed; once more, owing to momentum, the compression pressure far exceeds that which would be due to the static head of the liquid, and permits a high thermal efficiency. The admission valves for combustible mixture and the exhaust valves for burnt products are placed in the combustion chamber, and the valves for admitting fresh water are placed circumferentially round a vertical valve box situated between the combustion chamber and the bend which connects the horizontal pipe.

Some of the castings for these pumps at Chingford weigh upwards of 20 tons each. The contract price for the pumps and producer plant is £19,388, and they are being built by Messrs. Siemens Brothers' Dynamo Works, Limited. It is expected that the installation, which is the largest of its type undertaken up to the present, will be completed in December and that a test under actual working conditions will then be carried out. The contract has been accepted subject to a fine of £1,000 for every 0.1 lb. of fuel consumed in excess of the guarantee.

◆

COMPETITION FOR MINERS' LAMPS.

Under the auspices of the Acetylene Unions of the different countries, a competition for acetylene lamps for mines not containing fire-damp is opened from now under the care of the International Committee of Carbide of Calcium at Geneva. The prize or prizes will be awarded to the lamp or lamps which most completely fulfil the following conditions: Simplicity and regularity; cheapness; strength and lightness; easiness of upkeep; convenience in cleaning and refilling; resistance to upset; ease of handling and capability of being carried in the hand or being hung on the walls; solid material, light, durable, and unaffected by dampness or the results of the decomposition of the carbide; strong burner of long duration, and placed or arranged so as to avoid extinction from dripping water or by mine violences; production of gas as constant as possible, rational generation from the point of view of purity of the gas as well as the yield of the carbide; utilization of the present sizes of carbide intensity of 5/10 candle power as far as possible; duration of charge as long as possible. The competition will be divided into two categories: (1) Portable lamps for carrying by hand, duration of charge 8 to 12 hours; (2) portable lamps for carrying on the forehead, of extreme lightness, and a duration of at least 4 to 5 hours. At the discretion of the jury either one or two prizes may be awarded; of a total of 5,000 francs, which may be granted if two prizes are awarded, as to 3,000 francs for the best portable lamps for the hand, and as to 2,000 francs for the best portable lamps for the forehead. The models, with description, price of re-sale, &c., must be forwarded before March 20, 1913, to the International Committee of Carbide of Calcium, 5 Rue des Granges, Geneva. The jury will be composed of competent delegates from the different countries nominated by the respective Acetylene Unions.

LIGNITE AND ITS USES.*

By R. O. Wynne-Roberts.

The author, in another capacity, recently had the opportunity of collecting information regarding lignite and of presenting the same in a report to the government.

To-night it may be possible to supplement the report by discussing "Lignite and Its Uses" in a more general sense. It may, however, be necessary to incidentally refer to one or two items in the report because it is unavoidable.

Countless ages ago there were swamps and shallow lakes in which marsh-loving plants grow, deep waters in which algae flourished and aquatic mosses spread over the surface in tangled mats which, under the prehistoric condition, were such that these plants grow with a succulent freedom and rapidity unknown in later days. These plants died and fell into the water and by some preserving action of the water were gradually embalmed and fossilized. In course of time the deposit accumulated, fermentation took place and the vegetable matter was gradually altered in composition and character. This in time, and under increased temperature and pressure, became peat and afterwards converted into lignite and perhaps eventually became coal.

Coal is admitted to be the fossil remains of vegetation that flourished in the carboniferous period of the world's history, while lignite is that of the cretaceous and tertiary periods which are far more recent.

The nature of the compounds which go to build up coal of different kinds is still more or less a mystery, despite the fact that scientists have been investigating this subject for over 100 years. In nature there is a wonderful cycle of processes in continuous action by which the atmosphere is purified of the products of life and decay, through assimulation by vegetation, and under the influence of the sun's ray, the growing plant builds up its tissues from the carbon, hydrogen and oxygen, renders latent and storing the solar energy, and in the countless ages they were gradually converted into fuel.

According to Prof. Vivian Lewis, all the plants which were fossilized consisted of sedges and reeds, tree ferns, club mosses and trees akin to pine. The spores of club mosses of to-day give off a substance of so resinous in its nature as to resist the action of water and perhaps this has contributed to the preservation of plants in water. With some forms of vegetation the essential oils undergo oxidation and form resin and, these being more resistant to change, accumulate in masses of decaying vegetable matter so that large quantities of them are found in peat and lignite beds of Germany in a fossilized but little changed state, but whether they are to be found in this province, no information is yet to hand.

Peat, then, is merely decomposed vegetable matter, consisting chiefly of decayed moss and water plants, and is the lowest grade of fuel recognized in the classification of coals. It varies from yellowish or brown fibrous substance in which leaves and tissues of the plants are quite perfectly preserved through different stages of maceration to a dark brown colored material, in which little of the original structure can be recognized. Peat, after drying, is used for making coke, in gas producers, as domestic fuel, and in some countries it is briquetted. In the province of Schleswig-Holstein, a central power plant has been erected to supply electricity to 60 communities lying within a circle of 16 miles, and all power necessary is furnished by gas producers run entirely on peat.

Dr. Berguis, of Hanover, recently made some experiments in the artificial formation of coal. He made an apparatus consisting of a bomb bored out of a block of steel and having a coned lid, etc. He placed peat containing 85 per cent. of water in this bomb, and heated the same by an electric furnace to 660 degrees Fahrenheit and succeeded in obtaining coal similar to natural bituminous coal.

This experiment is confirmatory of the statement already made and it will be interesting to give the figures:

Material	Temperature in degree Fahrenheit	Time Taken Hours	Composition of the resultant Coal			
			Carbon	Oxygen	Hydrogen	Nitrogen
*Peat..	...	..	52.4	41.4	5.50	0.70
Peat...	480	8	74.3	19.4	5.20	1.07
Peat...	570	8	77.0	16.9	5.00	1.07
Peat..	645	8	81.2	13.3	4.65	0.89
Peat..	645	24	84.0	10.4	4.62	0.95
Peat..	660	11	85.2	10.4	4.50	....

* Composition of dry peat before treatment.

Lignite, again, is also formed by a mass of compressed and partly altered vegetable matter. Sometimes stems are found in it presenting the appearance of undecomposed wood. Lignite contains a larger proportion of oxygen than does coal. It is sometimes called fossil wood, wood coal and brown coal. Some lignite, however, so closely resembles good bituminous coal as to be indistinguishable. There are many varieties of lignite, ranging from soft and plastic substance that can be spaded like peat, to hard layers which have to be blasted. Some contain more than 40 per cent. of water. Its color ranges from brown to pitch black.

According to the 1911 report of the Canadian Commission of Conservation, there are 7,500 square miles and 20,000 tons of lignite in Saskatchewan, of which about two-thirds are located in the southeast portion.

The map exhibited will show the district where lignite deposits are found. That on the west is known as the Belly River formation and that on the south as Laramie formation. There appears to be in the neighborhood of Estevan, several lignite deposits down to a depth of about 600 feet; whether such layers extend into other parts of the province it is difficult to say, but it is probable they do.

Before discussing the uses of lignite, it will be desirable to refer to its quality. The quality of any fuel is dependent on the proportion of combustibles it contains. These consist of fixed carbon, and volatile matter. Sulphur is a combustible, but owing to its being present in lignite in such small quantities, it can be ignored. The impurities consist of shale clay and other inconsumable materials which give rise to ash, and this differs greatly with various kinds of fuel. Some fuels are now used containing over half their weight of impurities. Another item which has an important bearing on the use of lignite is the quantity of water which it contains.

Fixed Carbon.—Vegetable tissues are composed of carbon, hydrogen and oxygen. As these tissues, in the formation of coal, are not exposed to atmospheric conditions but are altered out of contact with air, the three chemical elements named rearranged themselves. For instance, carbon combining with oxygen forms carbon dioxide; carbon and hydrogen formed inflammable gas and hydrogen with oxygen formed water. The conditions which facilitate the formation and escape of these gases also favor the formation of coal having a high percentage of fixed carbon. Such conditions are pressure, heat, folding and erosion of the local bearing strata. So, in the Rockies, where great disturbances have occurred by tilting of the rocks, folding of the bed plane, and generally causing a tremendous pressure to take place, the coals found there have a higher percentage of fixed carbon than in those found on the east of the mountains, where no such disturbances have taken place, and this is one reason why lignites are relatively low in fixed carbon.

---

* Paper read before Regina Engineering Society, December 5th, 1912.

Volatile Matter.—Anthracite from Bankhead contains about 11 per cent. of volatile matter, and 85 per cent. of fixed carbon, while Souris lignite from Sutherland mine, for instance, contains 35 per cent. and 39 per cent. respectively. It will therefore be seen that in the anthracite the high percentage of fixed carbon gives off a hot, sustaining fire under steam boilers, whilst in the case of lignite the gases constitute one-half of the combustibles.

It is instructive to compare lignites from various countries and to contrast the same with American coal.

	Moisture	Computed to dry Bases			Heat value of coal as fixed
		Vol. Mat.	F. Car.	Ash	
1. Saskatchewan lignite	29.7	49.0	42.9	8.0	7520
2. Alberta lignite	8.3	37.5	51.5	11.0	10740
3. North Dakota lignite.	35.78	45.00	45.05	10.0	7279
4. California	17.36	46.5	35.0	18.8	8530
5. Texas	33.71	44.0	45.0	11.10	7348
6. Italy	12.5	38.0	45.5	15.16	9350
7. Hungary	24.0	48.6	24.3	21.2	5750
8. Germany	52.7	44.5	43.8	12.3	4500
For comparison with best American coal from West Virginia	1.36	15.0	78.0	7.7	14420

It will be observed that the moisture content varies greatly. In one case it was as much as 52.7 per cent., and yet the gas produced from it was good.

8. From Kerpely catalogue.

The production of lignite, according to information received, is as follows:

		Tons.
1911	Saskatchewan	204,000
1910	North Dakota	400,000
1910	Alberta	784,000
1910	Texas	881,000
1911	Germany	8[illegible],000,000

The use of lignite in this province has not yet become extensive. One of the principal consumers in the Robin Hood Mill Company, where a new type of furnace will shortly be installed to consume it. Estevan Power Steam Plant is run on lignite. The Rouleau Electric Plant is operated by means of producer gas from lignite.

Lignite is occasionally consumed at the power plants in Regina and Moose Jaw. Special tests were recently made at Weyburn and Estevan in connection with the use of lignite under boilers. Alberta lignite is used at Edmonton, Calgary, and Lethbridge for raising steam; these three employing chain grates and mechanical stokers.

The Canadian Mines Branch in 1908 carried out a series of tests in raising steam and with gas producers, with a large number of Canadian coals and lignites. These tests were made at McGill University, Montreal, and are dealt with in reports published recently.

Collecting the results obtained at those places where relative figures are reported, they can be tabulated as follows:—

Steam Plant.—Estevan—One pound of lignite as fired, equivalent evaporation was 3.76 pounds of steam from and at 212 degrees Fahrenheit. Weyburn—One pound of lignite as fired, equivalent evaporation was 4.13 pounds of steam from and at 212 degrees Fahrenheit. Montreal—One pound of lignite as fired, equivalent evaporation was 3.91 pounds of steam from and at 212 degrees Fahrenheit. Average, ⅓ of 11.80, 3.93 pounds.

Thermal efficiency based on combustible consumed·

Estevan	50.85%
Weyburn	56.01%
Montreal	52.5 %

Average, ⅓ of 159.36, 53.12%.

Reference will later on be made to results obtained elsewhere, but it will be seen that in very instance the evaporation and efficiency were low. In each case the furnace and grade were practically the same as for superior coal. It is evident that much better results ought to be and are, no doubt, obtainable by adopting furnaces and grates better adapted for the consumption of lignites.

The United States Bureau of Mines conducted tests at Williston, North Dakota, steam plant, where a semi-producer furnace was built; superheated steam was used with Argand blower, and air was preheated in coils at the back of the boiler. The equivalent evaporation from and at 212 degree Fahrenheit was 3.17 pounds of steam and the overall thermal efficiency was 53.79 per cent. The moisture content of the lignite averaged 42.61 per cent.

Other steam tests were made at St. Louis, but the results were not so good.

Enough has been stated regarding the results of test obtained in raising steam with raw lignite.

It is well now to refer to results obtained with gas producers.

Two tests were made at the McGill University, Montreal, with the result that one brake horse-power per hour was obtained on a consumption of 2.58 and 2.70 pounds of lignite or an average of 2.64. These are the only tests made in Canada of which information has been received. Reference will be made to American tests later on.

Assuming that 18 pounds of steam are required per indicated horse-power hour to run a first-class steam turbine, then at least 4½ pounds of lignite are required, and with gas producers at least 2⅔ pounds.

The American gas producer tests will now be referred to.

So that this paper will not be overloaded with statistics, it may be stated that at St. Louis (Mo.) a large number of American coals and lignites were tested under steam boilers and in gas producers, and it required 8.46 pounds of lignite similar to that locally produced to generate one electrical horse-power at the switchboard when consumed under a steam boiler as compared with an average of 2.93 pounds of various lignites when used in gas producers.

In Texas the average consumption of raw lignite during last year at a 5,000 h.p. gas producer installation was 4 pounds per kilowatt hour, after allowing for all contingent losses, etc.

In these cases, with the exception of Williston, where the air was preheated, no attempts were made to utilize the waste heats.

You will readily understand that after the coal has been converted into gas and consumed under the boiler or in the gas-engine, there is much sensible heat left. If means were adopted to utilize the same by way of economizers, waterheaters, etc., the fuel consumption would doubtless be reduced.

It will be interesting now to discuss what is being done in Europe.

As has already been stated, peat is the forerunner of lignite, and if it can be used for any purpose with efficiency, then it is reasonable to expect equal, if not better, results with lignite.

Mond gas plant has been installed at Orentana (Italy) to consume 100 tons of peat per day. Part of this gas is used in three 500-b.h.p. double-acting gas engines driving alternators in parallel. The current is distributed over the surrounding district and to the town of Pontedva, 14 miles away. Another plant gasifies German peat containing 40 to 60 per cent. of water and producing 85,000 cubic feet of gas having a heat value of 150 B.t.u. per cubic foot out of every ton of theoretically dry peat.

Mond gas plant is economical if the ammonia can be recovered, but so far as the information extends at present, the cost of commercial sulphuric acid delivered in Regina is too great for this.

Reference may be made to the Volcker furnace, which is shown on cartoon. A test was made at Leipziger Cotton Mills, Leipzig, Linderau, Germany, in 1903. There were three boilers, each having a water heating surface of 302.5 square meters and in 1908 another test was made at the Renate Mines, Germany. The general results are given below:—

	Leipzig.	Renate.
Water heating surface of boiler	907.5 sq. m.	267. sq. m.
Superheater heating surface ..	107.5 sq. m.	87.8 sq. m.
Grate area	25.92 sq. m.	10. sq. m.
Heat value of lignite combustible	2503 cal.	2019 cal.
Duration of test	7¾ hrs.	8 hrs.
Coal consumed	34,620 kg.	19,900 kg
Coal consumed per sq. m. grate area and per hour	....	247 kg.
Water evaporated	101,012 kg.	41,324 kg.
Water evaporated per sq. m. heating surface per hr. ..	....	19.19
Actual evaporation	2.86	2.08
Water from 0 deg. C. to steam 100 deg. C.	2.91	2.34
Steam pressure	10.8 atms.	12.8 atms.
Temperature of feed water....	....	36.4 deg. C.
Temperature of superheated steam	245 deg. C.	356.2 deg C.
Percentage of C.O. in flue gas	15%	12.7%
Heat absorbed in calories per kg. of combustible	1,826.3 cal.	1,489 cal.
Net thermal efficiency	72.9%	73.7%

As no information is given as to the proximate or ultimate analysis of the lignite, it is not possible to express any opinions to the similarity of the lignites used to that found in this province. Even allowing for some difference in quality, the results obtained are high.

In connection with gas producers, it is possible to obtain a certain quantity of steam as well as gas by means of water jackets on producers, economizers on gas engine exhausts, etc. With regard to water-jacketed producers, this has been adopted to a small extent in the States and in England, but apparently this arrangement has been more developed in Germany. One of the cartoons on the wall depicts a Kerpely producer encased in a Marischka boiler, in other words, the producer is provided with an enlarged water jacket, while the fire brick lining which is usually found inside producers is entirely absent in this case.

A large installation of these combined producers and boilers have been erected in connection with the Vienna municipal gas works, at Leopoldau.

Coke breeze is used as fuel; this has a calorific value of about 10,000 B.t.u. per pound and contains 11.75 per cent. water and 15.8 per cent. ash.

These producers are 2 metres or 6 feet 8 inches in diameter, and have 55 square metres or 600 square feet heating surface. One kilogram of coke evaporated 1.13 kg. of water, and 11.4 kg. of steam were obtained per sq. metre of heating surface per hour at a pressure of 76 lbs. per sq. in.

The temperature of the feed water was 45.9 deg. C. or 114.6 deg. Fahrenheit, and that of the gas at the outlet of the producer was 220 degrees C. or 428 degrees Fahrenheit. As the temperature of the hot gas in other producers is ordinarily about 1,100 degrees Fahrenheit, it will be seen that a large absorption of sensible heat had taken place. The net value of the gas was 1,218 cal. per cubic metre, or 134 B.t.u. per cubic foot.

The gas had the following average composition:

Carbon dioxide	CO............	2.78%
Carbon monoxide	CO............	29.84%
Hydrogen	H............	9.12%
Marsh gas	CH............	0.8 %

The loss of carbon in ash was 1.43 per cent.

The heat contained in the steam was 689 caloric; 3.8 cubic metres of gas were produced per kg. of coke, the specific heat of which was 0.31, and the heat value obtained was 3.8 c.m. × 220 deg C. × 0.31 — 259 calories.

To gasify the coke 0.18 kg. of steam was required per one kg. of coke.

The efficiency of the combined producer and boiler may be calculated as follows:—

Heat value of coke	5,636	calories
Heat value of steam used	110	”
	5,746	calories
Heat obtained from steam	689	calories
Heat obtained from gas	4,628	”
Heat obtained from temperature of gas......	259	”
	5,576	calories

The total net efficiency of combined producer and boiler was $\frac{5,576 \times 100}{5,746}$ equals 97 per cent.

The heat balance may be struck off as follows:—

11.99%	in producing steam.
80.54%	in the gas produced.
4.51%	sensible heat of hot gas.

When the gas was cleaned and cooled ready for use in gas engines, the efficiency was reduced to 92,53 per cent. as compared with about 85 per cent. in other producers. As one kilogram of coke produced 1.13 kg. of steam of which 0.18 kg. was required in the generation of gas, the balance —0.95 kg.—was available for other uses. For example, as in this case, if 15,000 kg. of coke were consumed in 24 hours, the 600 kg. of steam per hour is available, which is equal to at least 60 h.p.

As this test was made with gas coke, it is a question that requires answering, whether equal results could be obtained with the consumption of raw lignite.

Another test made with the same make of producer, but without the encasing boiler, is stated to have resulted in a net thermal efficiency of 86.87 per cent., when consuming Syrian lignite of Austria.

Saskatchewan lignite is stated to correspond approximately in quality to the lignite of Bohemia and Upper Hungary. One German firm of engineers claim that the efficiency of their producers average about 80 per cent. and state that the efficiency of gas-fired boilers averages from 80 to 85 per cent., so that the combined efficiency of separate producer and boiler will therefore be 68 to 72 per cent. And, further, if Bonecourt surface combustion is applicable, then the combined efficiency would be in the neighborhood of 90 per cent. Whether Bonecourt's system can be applied depends on the quantity of dust and carbonaceous matter that may be discharged with the gas from the producer.

There is another method of using lignite for raising steam, and this is by using dust fuel. Lignite, in this case, would have to be dried and pulverized and the makers claim this can be done effectively and cheaply. The appliance which disintegrates the coal also acts as a fan and blows the fuel along into a burner fixed in the centre of a specially designed vertical boiler, and there ignited.

Four tests were made in Johannesburg, South Africa, with coal of the following composition:—

Moisture	2.15%
Volatile matter	22.80%
Fixed carbon	57.55%
Ash	17.50%

The average results of these tests were:—

Duration of tests in minutes	95
Steam pressure, in lbs. absorbed	189
Steam temperature, in deg. Fahr.	576
Feed water temperature, in deg. Fahr.	70
Percentage of CO_2, in flue gas	16.8
Factor of evaporation	1.265
Coal fixed per hour, in lbs.	3,451
Water evaporated per hour actual, in lbs.	25,190
Water evaporated from and at 212 deg. F., in lbs.	31,860
Water evaporated per lb. coal actual, in lbs.	7.30
Water evaporated from and at 212 deg. F., in lbs.	9.24
Net efficiency, per cent.	80.4

It will be unnecessary to discuss further the question of generating power by means of steam boilers or gas producers and sufficient proofs have been submitted to show that it is possible and in view of the cost of imported fuel and local conditions it is also cheap.

Before proceeding to another phase of the problem of using lignite, it may be desirable to submit a few points which might be profitably debated.

1. Lignite is a highly oxygenated fuel, containing a large proportion of volatile matter and moisture.

2. The efficient consumption of lignite for raising steam is dependent on the furnaces and boilers being specially adapted for its use.

3. If lignite is used in the solid form, there should be a large grate area, deep, fuel bed, efficient air preheater, and an ample sized combustion chamber.

4. Lignite is adapted for generating power by means of gas producers and engines. The producers, etc., must be designed for this particular fuel, as the grate area must be larger, fuel bed deeper, less steam is required and less tar is produced.

5. Ample provision should be made for reducing the formation of clinker and for its removal by mechanical means, because, barring by manual labor is both inefficient and expensive.

6. More economical development of power from lignite appears to be possible when the surplus heats are absorbed by suitable economizers, etc.

7. The most promising method of developing power from lignite on a large scale is by gas producers and engines with the installation of waste heat utilizers, together with steam boilers and engines.

8. Every unit of increase thermal efficiency obtained with any type of power plant means a tangible saving in dollars and cents for the steam user.

There is another method of using lignite and that is by converting it into gas by ordinary distillation process. This has been fully set out in the report and consequently only a general reference to this subject can be made to-night.

It is a question for the public to decide whether they want artificial gas of the same quality as is made in other Canadian cities, which can be used for lighting, cooking, heating and power, and which will cost more to supply owing to the great distance from which the gas-coal must be brought, or an artificial gas possessing small illuminating power but of good enough quality for heating, cooking and power, made from local fuel and costing less to supply. Natural gas is, of course, superior to both.

Lignite gas, which name is applied advisedly to differentiate it from ordinary coal-gas, can be made in an ordinary gas works plant, but the heat required for distillation will probably be less and therefore the cost of production will be less. Moreover, as lignite distils more quickly than ordinary gas coal, more gas can probably be made in a given time, and therefore smaller plant will be necessary. If the public should desire the lignite gas to be richer in lighting power, then it can be enriched at small cost.

Gas work may not be so familiar to some of you as steam and producer plants and therefore a short elementary description will be given of the process.

The gas works plant consists of retort benches, exhauster, condensers, scrubbers, washers, purifiers, station meter and gas holder with tanks for tar and ammoniacal liquor, all of which are connected together by pipes.

The retort benches are virtually ovens in which are placed a number of fire-clay retorts built over a furnace. These retorts are either circular, D shaped, or oval, in cross section. They are often "singles," that is, they are closed at one end and fitted with a cast iron mouthpiece at the other; in other places two retort benches are placed back to back and the retorts are "throughs," that is, they are open from mouthpiece to mouthpiece. There are flues from the furnace beneath surrounding these retorts to heat them. These furnaces, in small work, are direct fired with coke, but in larger work regenerative and producer furnaces are built with passages to preheat the air so that when the gases from the furnace meet and mix with the hot air, and burn in the combustion chamber, intense heat is generated. This is circulated around the retorts and finally passes up the chimney stack.

Retorts are usually laid horizontally but sloping retorts are in use, as well as chamber retorts. The latest development is the vertical retort, which consists of fire-clay rings surrounded by flues. These verticals are heated by producer furnaces, and as the coal is carbonized into coke, it gradually falls in the chamber. Outside the lower part of the vertical retort there are flues to preheat the air, and this at the same time cools the coke, so that when it is discharged it requires very little quenching.

Returning again to the horizontal retort, coal is charged into it, and the lid on the mouthpiece closed and made airtight. The externally applied heat causes the coal to be carbonized or distilled, gases and vapors are driven out and as there is but one outlet they perforce must travel up the ascension pipe from the mouthpiece into the hydraulic main when the heavier hydrocarbons and some vapor are condensed and deposited.

As the gas would, in the absence of pumps, have to force its way through water in the hydraulic main and through the condensers, washers, scrubbers, purifiers, meter and into the gas holders. There would naturally be some back pressure thrown on the retort and this would reduce the quantity and quality of the gas produced from each ton. So, an exhauster is installed, the function of which is to pump the gas out of the retort and thereby to keep the pressure on the retorts at a minimum, and also to drive the gas through the various clearing appliances and into the gas holder.

The gas, then, after it passes through the hydraulic main, flows along the "foul main" into the condenser, in both of which more tar and ammoniacal liquor are condensed. It then has to pass through washers and scrubbers where the remainder of the tar and ammonia are extracted, as well as some of the impurities, such as carbon dioxide and hydrogen sulphide.

The next step is to purify the gas, and this is done by means of lime or oxide where the remainder of the carbon dioxide and sulphuretted hydrogen are removed.

The gas, after passing through the various processes of purification, is stored in a gas holder and delivered to the cities as it is required.

There is another process by which gas can be manufactured, and that is by means of coke ovens where a large quantity of coal is distilled at one time.

The gas obtained from lignite by any of these methods will be equal to about two-thirds of the heat value of first-class coal gas, but much less so far as illuminating power is concerned. But in these days gas is not consumed in old-fashioned flat flame burners. It is burned in mantles which are heated to incandescence, thus causing the rare-earths to give off the brilliant light which we all know. Lignite gas used in this manner will yield a fair amount of light, and if desired, can be so enriched as to give any candle-power. The principal aim of gas engineer is to supply good and cheap heating gas. In many places in Europe coal-gas is now supplied of practically the same heating value as that to be obtained from lignite, because it is cheaper to make.

In the United States two-thirds of the gas supplied is made by another process, namely, the carburetted water gas. The plant for making this gas consists of generators which are similar in many respects to producers. Regenerators, which are chambers filled with checker or baffle brickwork, are in duplicate. The generators are heated to incandescence by means of air blast; the gas passes up out the regenerators, where they are burned, and the brickwork raised to a very high temperature. Steam is then admitted into the generator and in passing through the hot fire in the producer and then through the regenerators, it is converted into its component parts, namely, hydrogen and oxygen. The latter combine with the carbon to form carbon monoxide and the hydrogen is made free. Thus two gases are obtained, hydrogen and monoxide, which have higher values than producer gas, but not much lower than lignite gas. With gas producers, however, the process is continuous, whilst with water gas plant, owing to the fire being cooled by the injection of steam, it is intermittent.

The water gas burns with a blue flame and will yield no light, but oil is carburetted by volatilizing and fixing it and this raises its lighting power to that of the best coal gas.

Although examples of the production of water gas by consuming lignite is not yet to hand, there does not appear to be any reason why it should not be as feasible as when using coal. Until further information is collected, it will not be wise to dogmatize on this subject.

Reference might here be made to Bonecourt surface combustion. Gas is made to pass through a porous plate of, say, fire-clay, and is ignite on the outer side. The flame is of the ordinary white kind you see when burning coal gas. Then air is admitted with the gas and the flame alters in appearance and finally disappears, but gas continues to be consumed, maintaining the surface white-hot, whilst the inner surface remains cool. This form of heating can be applied to grilling, evaporating, etc.; the latest domestic application is to toast a few million pieces of bread per day in large cafés. This system can be applied for industrial purposes, for instance, it can be used to welt lead, to heat crucibles, muffled furnaces. The heat obtainable can be made so intense that it is difficult to find a material that will withstand it.

Steam boilers can be heated by this method, and when gas is made available it may be used to heat hot air, steam or hot water boilers for house warming.

What appears to be a simple adaptation of surface combustion is an arrangement for fitting ordinary drawing-room or other fireplace with a gas fire. The gas in this case passes through a bed of loose sand or granulated substance and the gas burns on the surface as already described.

This method of consuming gas results in high efficiency and economy.

Much is heard to-day of cooking by electricity and, as an incidental feature of this paper, it may be interesting to make a simple comparison.

Electricity sold at, say, 3 cents per kilowatt, having a heat value of 3,400 B.t.u., which equals 113,300 units for each dollar, and allowing an efficiency of 75 per cent., then the available heat is about 850.00. Coal at $7 per ton, having a heat value of, say, 10,000 B.t.u. per pound, will give 2,860,000 heat units for one dollar, but as the efficiency in this case is as low as two per cent., then the available heat is 57,200 per dollar.

Artificial lignite gas, sold at, say, $1 per 1,000 cubic feet, having a calorific value of 450 B.t.u. per cubic foot, will theoretically yield 450,000 heat units per dollar. The efficiency in this case is about 25 per cent., so, only 110,000 units are obtained per dollar. If Bonecourts system is applied, then the efficiency will be, say 50 per cent., in which case the heat value available will be 220,000.

The comparison will consequently be:—

Electricity at 3 cts. per kw.....	85,000	heat units per dollar
Coal at $7 per ton............	57,200	" " "
Lignite gas at $1 per 1,000 cubic feet	110,000	" " "

The water, which is condensed from gas and the additional quantity used for washing gas, contains ammonia This ammoniacal liquor is distilled and the ammonia drawn off and passed over acid.

The product, sulphate of ammonia, is an excellent fertilizer, and can also be used for rendering wood less inflammable. Ammonia is also used in connection with refrigerating plant, and by another process is used for the manufacture of explosives.

Having disposed of the question of developing power by steam producer-gas, lignite-gas and water-gas, we may now turn our attention to briquetting of lignite.

This is not so easy of solution. In raw lignite, one-third of its weight consists of water, and when it is air-dried, about one-half of the water is evaporated, but the lignite breaks up or crumbles and in that condition it is not so easily handled. Stokers object to it because it means more labor in firing and needs more careful watching. This can be obviated by using mechanical arrangements. Steam users object because at present full steaming capacity of the boilers are not secured, and there is more loss due to the small particles falling between the fire bars. This may be improved upon by installing lignite consuming furnaces. Householders object because it is too flashy when burned, and requires more attention, and this can be improved by using briquettes.

In this province we have no available asphalt supply; there are no gas works to provide coal-tar-pitch; but it is quite possible to utilize local material which will answer as agglomerations or binders for making briquettes.

If a lignite gas works is installed, some distillates from the tar, such as pitch, paraffin, wax, etc., may be useful.

A sample of local lignite was sent to a briquette machine maker and this he made into briquettes which are on view to-night. Owing to the smallness of the quantity of the sample, the maker referred to found he was unable to carry out the experiment as efficiently as he would wish. Consequently, the briquettes before you are not good specimens. Samples A and B have been briquetted by a certain special steaming process without the use of any binder, but these briquettes do not appear to be satisfactory. Samples C to F are made with five per cent. pitch, sample F being the best. It is hoped that further experiments will be made. Other experimenters are endeavoring to find a cheap and simple process by which raw lignite can be satisfactorily briquetted.

What promises to be a solution of this problem is the carbonization of lignite at low temperatures. Although North American lignite has not been subjected to this treatment, non-coking Illinois coals have, and a few of the results obtained may be stated.

When the coal was distilled for an hour at a temperature of 500 degrees to 900 degrees Fahr., the percentage of fixed carbon was increased more than 25 per cent., and there was a corresponding decrease in volatile matter, and furthermore, the fuel became smokeless. Another feature of low distillation of Illinois coal is the production of gas of exceedingly high heating value, almost equal to that of natural gas. Illinois coal is not of high quality, nor has it the propensity of making coke, and in these respects it is similar to lignite. Prof. Lewis, in another experiment, found it was cheaper to manufacture gas at low temperature of 720 deg. Fahrenheit and the value of the gas was higher, whilst more coke and ammonia products were obtained. The temperature of ordinary gas-coal distillation is about 2,200 deg. Fahrenheit and the composition of the tar produced is quite different from that at low temperature. The latter yield paraffin oils valuable for lubrication and power purposes.

In Germany thousands of tons of tar are annually produced by the distillation of lignite at low temperature. Gas oil extracted from the tar is used for making oil gas, and it is stated to be equal in value to the residuum of crude petroleum, known in the States as Pennsylvania gas oil, such oil could probably be used to enrich lignite gas. The German manufacturers also obtain paraffin wax from lignite tar, also the following:—

Solar oil is obtained by distillation of tar, and this oil is used for driving motors.

Putrol is a yellowish cleaning oil, used for cleaning greasy metal, for extracting and producing wagon grease.

Gas oil is a reddish brown oil used for producing oil gas.

Paraffin oil is used principally for driving Diesel motors.

Creosate oil for impregnating timber.

Peat, as far back as 1786, was converted into gas and coke and the tar more or less resembles lignite tar. Fifty years ago gas was made from peat in New England, New York and Jersey States, but the cost and quality of peat rendered the process unprofitable in these and other places.

There is, however, no known process by which lignite coke can be made into a coherent mass like gas-coke, metallurgical coke. As there are plenty of coals in the Eastern States which will produce good coke, very little attention has been paid to solving the lignite-coke problem.

In response to enquiries, the author has interested a number of people in different parts of Europe and America in this matter, and it is to be hoped that a process can be found whereby the raw lignite and lignite-coke can be made into serviceable fuel.

It will have been observed that low-temperature distillation of lignite promises to be the solution, and it may be advantageous at the point to outlive what the author considers the possible scheme.

The lignite should be partially distilled at low temperature, the gas to be either distributed for use in the district or in firing the furnace. The tar distilled to extract the paraffin and oils. The coke to be briquetted with some binder obtained from local products and waterproofed with paraffin, and made into a fuel which will equal any imported coal, and probably at a much less cost.

It will doubtless be recognized that whilst the information given to-night is limited, and necessarily supplementary to the report, which the author has prepared, it will require more time, funds and facilities to develop the enquiries and carry on experiments.

Lignite is out local fuel and it will manifestly be to the advantage of the community if fuller use can be made of it. If a central power plant is erected, its value will be circumscribed by the range to which it can be economically transmitted, and the increase in the consumption of lignite will be, say, 50 per cent.; but every farmer, householder and industry requires fuel, and the cheaper it can be supplied, so much the better. If, however, its quality can be improved for transportation and general use, then the demand will doubtless increase greatly, because it has the advantage over imported fuel, inasmuch as less freight has to be paid.

THE NEW CANADIAN PACIFIC LINERS.

Two new vessels for the Pacific service of the C.P.R. are now being completed at the Fairfield Works in England; the second, which was launched last week, is the eighth constructed by the Fairfield Company for the same owners. It will surprise no one who knows of the courage of the Canadian Pacific Railway, to learn that the new vessels will be by far the largest trading between the American continent and Japan and China, and, further, that they represent in their design the highest achievement in naval architecture, alike from the standpoints of safety, comfort, and economy. As regards the first, the water-tight bulkheads are more closely spaced than has hitherto been usual, so that four compartments can be opened to the sea without affecting the flotation of the ship. As to comfort, the 200 first-class, 100 second, and 800 third-class passengers to be carried are ensured every convenience which experience can suggest. As we hope later to illustrate the vessels, we need only here remark that one—namely, the Empress of Russia—is decorated in the Louis XV. and Louis XVI. styles, whilst the second, the Empress of Asia, is treated according to the Georgian period. The first-class cabins are all in a deck-house, 340 ft. long, on the bridge deck. Whilst the rooms are nominally for two persons, the arrangement is such that when one person is occupying a room, all evidence of the other berth is hidden, leaving only a single brass bedstead with the other stateroom furniture. In nearly every case each pair of cabins can be converted into a suite. The vessels are of 15,000 tons gross, the length being 590 ft., the beam 68 ft., and the depth 46 ft. A considerable amount of freight, particularly of the perishable type, can be carried. There is an innovation in connection with the form aft, as the vessels have been given a cruiser stern, which increases the water-line for a given over-all length and facilitates the propulsion, while adding to the available deck area aft. There is the further advantage that many of the lifeboats can be carried over the poop, and here it may be noted that boats are provided for the maximum number of passengers arranged for. The vessel is propelled by turbines, with the construction of which the Fairfield Company have had very large experience. A high degree of propulsive efficiency is thus sure to result.

THE RISE OF TEMPERATURE ASSOCIATED WITH THE MELTING OF ICEBERGS.

By Prof. H. T. Barnes, D.Sc., F.R.S., McGill University.

In a letter to Nature, published in the issue of December 1, 1910, I showed by means of microthermograms taken on a trip to Hudson's Straits that an iceberg melting in salt water produces a rise of temperature. The experiments were performed on the Canadian Government steamship "Stanley," and indicated that when approaching ice a rise of temperature occurred followed by a rapid fall of temperature a quarter of a mile abeam of the 'berg.

During the past summer I had an opportunity of examining in detail the temperature effects of icebergs. The Canadian Government placed its steamship "Montcalm" at my disposal for the tests, and three weeks were spent through the Straits of Belle Isle. Careful records were made of the temperature effects of icebergs and land. These tests have shown conclusively that it is the rise of temperature which is the direct action of the melting iceberg, and that when a fall of temperature is observed near ice it is due to the action of a colder current in which the iceberg is floating, and is not due to the cooling influence of the ice. Cooler currents may exist throughout the Arctic Current, whether accompanied by ice or not, but the presence of the ice causes a zone of warmer water to accumulate for a considerable distance about it.

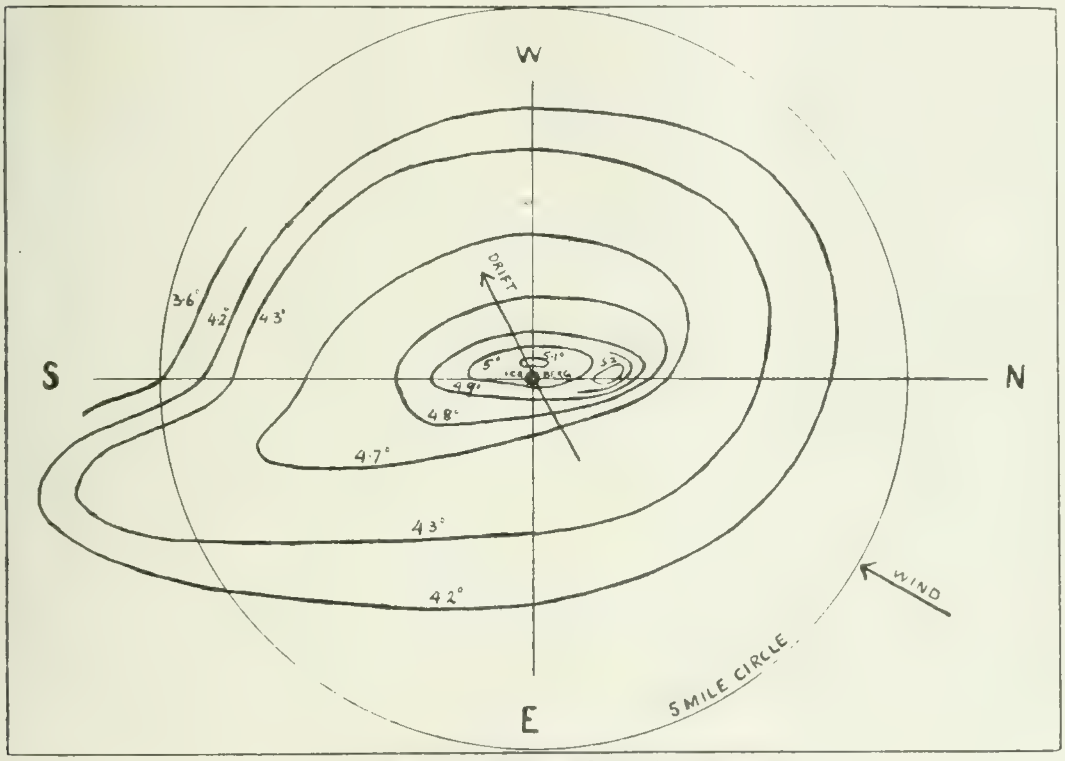

Fig. 1.—Isothermal Lines Around an Iceberg.

The icebergs I studied in the Straits of Belle Isle and off the eastern end of the Straits in the Labrador Current showed no appreciable cooling, even within a few yards of them. The rise of temperature approaching an isolated 'berg was somewhat over two degrees Centigrade. In Fig. 1 I show the isothermal lines about a typical 'berg off the eastern end of the Straits of Belle Isle. This diagram was obtained by arranging a number of courses for the ship from all sides up to a radius of six miles.

As a good illustration of how icebergs and groups of icebergs affect the water temperature I show a microthermogram in Fig. 2, taken from the records made passing westward through the Straits of Belle Isle. In every case the approach to ice caused a rise of temperature.

The explanation of this effect which I gave at my Friday evening discourse at the Royal Institution last May was founded on Pettersson's theory of ice melting in salt water. By this theory, which can easily be verified by a simple experiment, ice melting in salt water produces three currents: (1) A current of salt water cooled by the ice which sinks downward by gravity; (2) A current of warm salt water flowing towards the ice; and (3) A current of light fresh water from the ice rising and spreading out over the surface of the salt water.

I at first thought that it was this surface current of fresh water that influenced the microthermometer. The fringe of this lighter water would be warmer than the sea water on account of the action of the sun and scattered radiation, which is very strong at sea. The lighter water would retain the heat because it could not mix readily with the sea water. Near the iceberg I considered that a fall of temperature would result from the cooling influence of the surface current of fresher water.

My recent tests have shown, however, that an iceberg melts so slowly that no effect of the dilution can be detected, even right beside the berg. I took a number of samples of sea water at different distances from icebergs as well as samples taken far from ice. These samples I carefully bottled and brought home to the laboratory, where they were most accurately tested by the electric conductivity method in the Physico - Chemical Department by Dr. McIntosh and Mr. Otto Maass. No possible error could result in this way, and the tests, being carried out at a constant temperature under the most favorable circumstances, there is no reason to doubt their correctness. The comparison shows no dilution due to the icebergs, which goes to show how quickly the melted water from the 'berg is mixed with the sea water. Larger variations were found at different parts of the sea than were obtained in the proximity of ice.

It is evident that an iceberg in melting causes only two of the Pettersson currents, i.e., a cold current which sinks downward carrying with it all the melted ice water, and a horizontal surface current of sea water flowing in towards the ice to cause its melting. By this means we should expect the sea in the immediate proximity of icebergs to be warmer than further away, because the sea surface current is moving in towards the 'berg and does not share in the normal vertical circulation which tends to keep the sea surface temperature cooler.

The iceberg, in causing its own current of warmer water, provides for its own disintegration. Abundant evidence is at hand to show the melting process going on under the water line.

In my observations of icebergs I was greatly struck with the large amount of air dissolved in the ice. The white color of the 'berg is due to innumerable air bubbles in the ice, and not to snow on the surface. An iceberg is very deceptive in this way. While it looks quite soft, the ice is so hard as to make it difficult to chop it with an axe. Ice water which I prepared for drinking on board ship with iceberg ice appeared to effervesce like soda water, merely due to the liberation of the air from the melting ice. It is possible that the sudden disappearance of 'bergs with a loud report is due to their explosion from accumulated air in the interior. I passed close to one berg which was casting off small pieces, apparently by the pressure of the pent-up air.

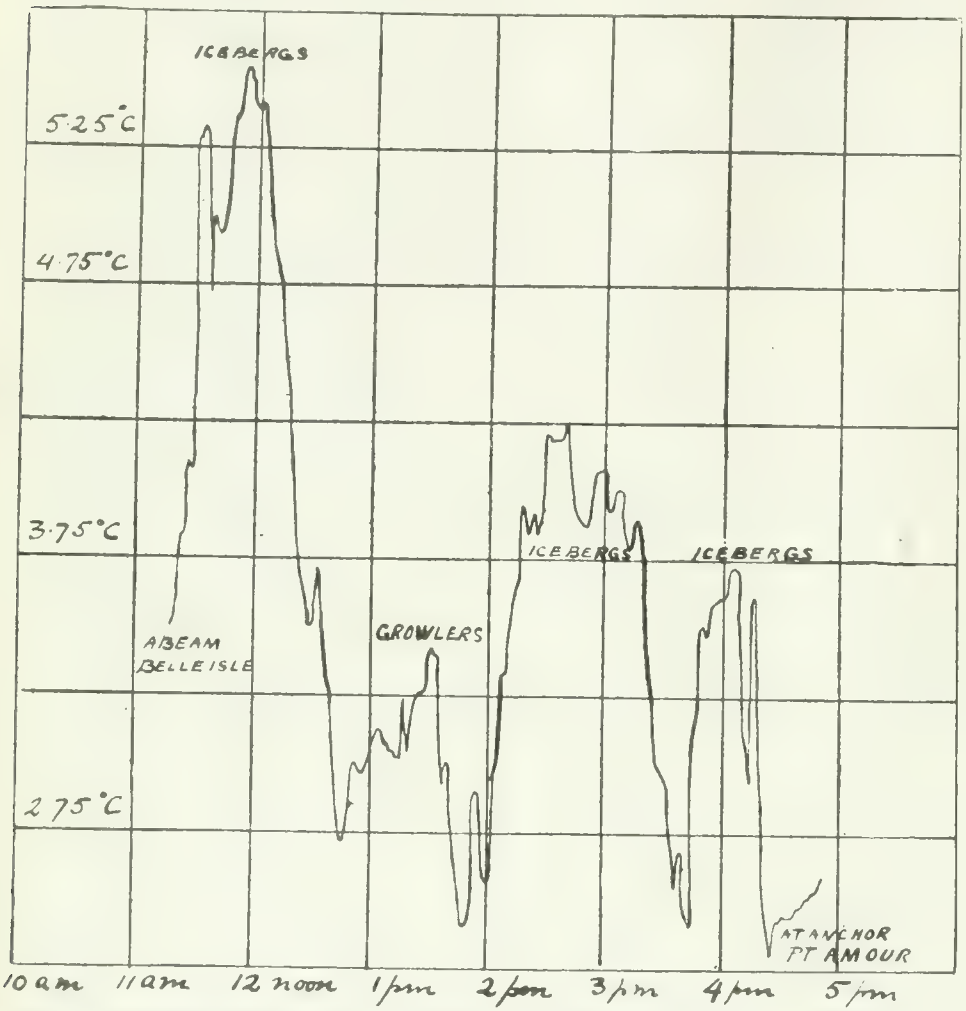

Fig. 2.—Microthermogram Taken Through the Straits of Belle Isle, Showing Effect of Iceberg Meeting.

While icebergs send the temperature of the sea up, land and coast line send it down. This was observed all along the coast in the Straits of Belle Isle. This effect is due to the action of land in turning up the colder under-water by the action of tides and currents. A great deal of work remains to be done in studying the effect of land and shoals on the temperature of the sea, but observations show the effect not only here, but on the Irish and English coasts.

From the point of view of the safety of our St. Lawrence route, the effect of land is most important. The iceberg causes us little worry because we have only a very short ice track, but to find means whereby the proximity of land can be determined is of the greatest importance.

WATER RATES.

The question of water rates comes under two heads, the engineering and the financial. The latter has probably been as productive of discussion as any single feature of waterworks operation. A few of the broader aspects of this subject particularly in the case of communities of 30,000 population or less were dealt with by Mr. Philip Burgess, consulting engineer of Columbus, Ohio, in a paper presented before the recent annual meeting of the Central States Waterworks Association. A summary of his remarks is given below.

In making an adjustment of the proper rates to be charged for water it is necessary to consider the three branches of service rendered, namely, domestic consumption, fire protection, and industrial use. The total annual revenue received must always at least equal the sum of (1) interest on investment, (2) operating and maintenance costs, and (3) annual fund required for replacement, commonly called depreciation. In considering these three factors every engineer knows how difficult it is to obtain from officials even a reasonable approximation of the cost of the first and third items. The books do not show a statement of the capital invested in the works nor is any attempt generally made to make the necessary corrections of the capital invested as may be required by replacements or even of extensions. Consequently, in making an adjustment of rates, the first step necessary for the expert is to determine the value of the works, generally assumed on the basis of the cost required to replace the works as they exist with other proper allowances.

In regard to the operating and maintenance costs, the former are comparatively easy to determine with accuracy. Maintenance, however, frequently is neglected or is charged to depreciation or replacement.

Waterworks and municipal officials may do a great deal of good towards the securing of equitable rates by seeing that the books are properly kept. The financial condition of the works may well be made public so that the consumers may know whether or not the water rates are reasonable and fair.

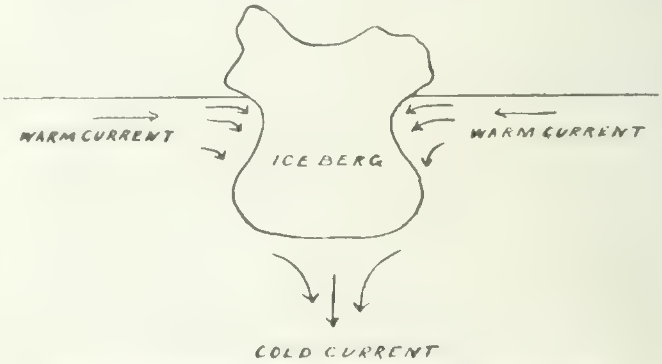

Fig. 3.—Currents due to Melting Ice in Salt Water.

In determining these rates it is understood that the total revenue is to be made up of that for domestic and industrial uses and for fire hydrants. The total amount received annually may be determined from the factors mentioned above, but the proper charge for individual service must always be determined by a very thorough study of local conditions by an expert.

In considering the matter of charges for fire hydrants and for other services directly of benefit to the community at large, it is now coming to be understood that the value of all such general services should be properly determined and charged for in all plants whether municipally or privately owned. In the case of a municipal plant, the charges for fire or hydrant and other public services should be met by a general tax levy in an amount equal to the value of the services rendered and the fund so received placed to the credit of the water department. The present more or less general policy of basing the charge for public service on so much per hydrant frequently results in poor service as well as poor compensation for the general public services rendered, and may place an unwarranted expense on the domestic consumers.

In the adjustment of rates for domestic service municipal officials may save much trouble for themselves and, perhaps, for the consumers by advocating and working for the installation of meters, which afford the only equitable basis for selling water.

The water served to a community must be of good quality. If it is thought desirable to correct a fallacious estimate of the cost of furnishing filtered water, as it is frequently stated that filtration of a public water supply necessitates rates at least 25 per cent. greater than would be required without filtration. The average cost of installation and operation of works, with and without purification, for a city of 30,000 population is shown.

Representative Waterworks Data for City of 30,000 Population.

	Without Purification.	With Purification.
Total cost of investment	$600,000	$675,000
Interest at 5 per cent.............	30,000	33,750
Replacement at 2 per cent.........	12,000	13,500
Probable cost of operation and maintenance	35,000	41,000
Total annual revenue required..	$77,000	$88,000

These figures show that the total annual revenue must be approximately 15 per cent. greater with filtered water than without. It should be noted, however, that the operating costs are less than one-half the total annual cost and it is well known that a plant may supply water at less cost per million gallons up to its full capacity than is possible at less than full capacity. Consequently, a waterworks should aim to get all the business possible, and it is believed that a filter plant will always bring in more revenue than it will cost. In fact, experience shows that the filter plant frequently is the only salvation for the waterworks, because you cannot make people buy poor water at any price.

As evidence of this fact the following figures refer to the waterworks situation at Niles, Ohio, a city which last year constructed a filter plant, under the direction of the writer: Ownership, municipal; population served, 8,000; estimated value of works, $125,000; investment per capita, $15.63; miles of mains, 21; number of hydrants, 125; source of supply, Mahoning River, unfiltered; quality of water, very poor; lift of pumps, 200 ft.; number of consumers, 900; consumers per mile of main, 43; total annual income, $8,758; total annual expenses, $14,942, including interest, depreciation, operation and maintenace.

In the above statement it is of interest to note that the waterworks were not self-sustaining although the rates charged for service compare fairly well with those charged in the neighboring communities. Attention is called to the low number of consumers per mile of main, namely 43, or about one-half of what might reasonably be expected were the supply of good quality. It is believed that the installation of the filter plant, although increasing the annual cost, will result in placing the works on a sound financial standing, due to increased business.

As compared with the above, the following data relate to the waterworks at Warren, Ohio, where there is in use one of the oldest mechanical filter plants in the United States: Ownership, private; population served, 10,000; estimated value of works, $268,000; investment per capita, $26.80; miles of mains, 31; number of hydrants, 161; source of supply, Mahoning River, filtered; quality of water, excellent; lift of pumps, 150 ft.; number of consumers, 2,300; consumers per mile of main, 74; total annual income, $38,783; total annual expenses, $34,466, including interest, depreciation, operation and maintenance; rates charged for service, 6-room house, $6, 1 bath and 1 basin, $2.75, 1 closet, $2.50, total annual, $11.25; sprinkling 50 ft. and street, $5.00.

In comparing the situations at the two plants, it is of interest to note that the Warren water supply has been maintained of excellent quality for many years, and that consequently the water is in general use, resulting in an excellent financial standing for the plant. It should be added, however, that the annual income at Warren contains a hydrant rental of $6,675 and that no hydrant rental is credited to the plant at Niles. As previously stated, however, there is a growing appreciation of the fact that all water departments, whether private or municipal, should be credited with and funds placed to their account for all public services rendered. Even on this basis, the conditions at Niles clearly warranted and required the installation of the purification plant even from a purely business standpoint, and not considering the health of the consumers.

EXPERIMENTS WITH KEROSENE FUEL.

An investigation of kerosene fuel is being conducted by the Engineering Experimental Station at the Pennsylvania State College under the direction of Prof. J. A. Moyer, of the mechanical engineering department. With the increase in the price of gasoline has come the demand for some cheaper fuel that will give as good results. Kerosene would meet the demands if a satisfactory carburetor can be designed, and it is with a view of determining the merits and defects of various types of carburetors that the investigation is being carried on. The price of gasoline has nearly doubled in this country in the past year, while in England the price has risen to 50 cents a gallon for "motor spirit." Many of the writers in the trade journals in England advocate the use of a mixture of gasoline and kerosene, but point out that without an efficient carburetor no such mixture may be used. Professor Moyer, who has made numerous experiments on smoke washing and electrostatic treatment of smoke, has already installed at the college a motor built to utilize the energy from either of the two fuels mentioned which is suitable for use on farms and country estates. Experiments will also be made on various mixtures, and a carburetor valve will be designed to shift the fuel supply automatically from a small gasoline tank, used only for starting, to the main kerosene tank. These experiments should be of interest to manufacturers and users of gasoline motors throughout the country.

IMHOFF TANKS.*

By **Henry N. Ogden.†**

The Imhoff tank is said to throw down 95 per cent. of the "capable-of-settling" suspended solids, and the advocates of the tank explain that the term "capable-of-settling" refers to that proportion of suspended matters in the sewage which will settle out in a measuring glass when allowed to stand quiescent for two hours. If Mr. Fuller's estimate of the amount of colloidal matter in sewage not capable of settling is 30 per cent., then the remainder, 70 per cent., is that which remains as precipitable after the use of chemicals; and if the Imhoff tank will throw down 95 per cent. of this it means that, of the total suspended solids, it will remove 66.5 per cent. This should be compared with the 50 to 55 per cent. which is obtained from strictly domestic sewage, and it is probably correct to say that the increased efficiency of the Imhoff tank due to the separation of the rising gas increases the deposit of solids from 10 to 15 per cent.

The second principle of the Imhoff tank is its remarkable performance in taking care of the sludge. Three reasons are assigned for this. In the first place, below the settling tank proper there is provided a large compartment in which the sludge is allowed to remain three to six months, during which time decomposition proceeds and effectively destroys the organic matter so that when finally the sludge is removed it is odorless and much reduced in quantity.

Perhaps no single element has worked more against a greater use of the septic tank than the fact that during the septic process offensive gases are given off. It is to the elimination of these odors that the energies of the inventor of the Imhoff tank were directed, and for this purpose he provides a separate tank for disintegration of solids, but he carries on that disintegration without producing odors. His second point, therefore, was that there must be through the sludge compartment no moving or renewed fresh sewage. The construction of the tank seems to solve this problem.

In the septic tanks the liquid sewage and the deposited sludge undergo decomposition together, while in the Imhoff tank all supernatant liquid passes through the tank so rapidly that no septic action is obtained, although in the sludge underneath a very high degree of septicization may be going on. It is said, therefore, that the organic matter in solution, either true or colloidal, is that part of any decomposition that is responsible for offensive gases, and that the deposited solids not subjected to renewed application of fresh sewage do not in their decomposition become offensive. This may explain why the Travis tank smells and the Imhoff tank does not.

The third point which seems to be fundamental in the design is that the deposited solids shall be overlaid with 25 or 30 ft. of liquid. Shallow tanks do not seem to be as effective as deep ones and the reason assigned for this is that the gases of decomposition which are produced in the lower strata must, on account of the high pressure, accumulate in greater volume and in their escape produce a greater separation of the sludge particles than in shallow tanks. It is to this action of the gases in the lower layers of the sludge deposits that Dr. Imhoff ascribes the marked porous condition of the sludge which gives it its rapid drying properties after being taken from the tank. The decomposition which goes on at the bottom of the Imhoff tank also gasifies and liquefies a large proportion of the solids originally deposited.

Based on experiments of Dr. Spilner and Mr. Blunk, chemist and engineer respectively for the Emscher Association, the fresh sludge deposited in the lower compartment contains, on an average, 95 per cent. of water. After remaining several weeks or months in the septic chamber it will contain only 75 per cent. of water, and about one-third of the original organic matter will have been either gasified or liquefied. Through these two agencies an original volume of 100 cu. yd. of fresh sludge will be reduced, according to their experiments and figures, to a volume of 16 cu. yd., a shrinkage in volume of about 84 per cent. They assert that through septic action only an original 5 cu. yd. of dry sludge matter will be reduced to 3.92 cu. yd., a reduction of 22 per cent. The largest part, therefore, of the reduced volume is gained by the loss in water, this being pressed out on account of the great depth of tank, or indirectly by the greater pressure of entrained gas.

Instead of being compact, non-porous and in texture much like asphalt or rubber, the Imhoff sludge is so porous that the contained water disappears readily, drying out so that it can be spaded in about five days and is thereby still further reduced in volume so that its volume is about 40 per cent. less than when emptied from the tank.

Since sewage disposal plants are generally built on the lowest ground where foundation soil is the poorest and where the ground saturation is most complete, it is inevitable that the cost of tanks 30 ft. down will be high. Wisner estimates the Imhoff tank to cost twice that of shallow tanks for the same volume of sewage, although the actual volume of the Imhoff tank is perhaps only one-fourth that of ordinary tanks in volume, but the storage compartment for sludge underneath is so great that the total volume of the tank is nearly that of an ordinary settling tank. Apparently the practice of Dr. Imhoff is to make the upper compartment large enough to hold about two hours' flow and to make the lower one twice this size. This makes the Imhoff tank large enough to hold about six hours' sewage flow, which is about the capacity of the more recently built septic tank.

The cost of the Imhoff tanks is higher even with smaller capacity because of higher unit prices in both excavation and masonry linings. The question, therefore, resolves itself into this: Is the greater sedimentation, the freedom from odor at the plant and the vastly reduced labor of disposing of the sludge sufficient justification for an increased cost of construction of the tank and for the patent fee which the inventor very properly claims? It has been said that there is no opportunity for equalizing the variable flow in so small a tank and that for best results a large sedimentation tank ought to precede the Imhoff tank action. But with every criticism considered, and with full appreciation of the difficulties of the deep tank construction, the boon of an odorless sewage disposal plant is so great and the elimination of the sludge problem so gratefully appreciated, that its rapid installation in this country cannot but follow its European successes.

---

STREET RAILWAY FOR PRINCE ALBERT.

An estimate of the probable cost of a street railway at Prince Albert, Saskatchewan, consisting of eight miles of track and eight or ten cars to start, has been submitted to the civic authorities by Mr. J. S. Townsend, of the Messrs. Stone and Webster Engineering Company of Boston, placing the figure at $275,000.

SEWAGE DISPOSAL IN ALBERTA.

In our issue of August 4th, 1910, we published a copy of a resolution passed by the Provincial Board of Health of Alberta calling upon municipalities to delay any contemplated sewage disposal undertakings until the Government had completed a plant, demonstrating what is purported to be a new system of sewage disposal, invented and patented by the engineer to the Board of Health under the name of "The Live Earth Bed System." In a further issue of September 1st, 1910, we published a description of the system, together with drawings, and also in an editorial called attention to the fact that the system was not new, but was apparently an adaptation of "Dibden's Slate Bed System," in vogue at several places in Great Britain for the treatment and digestion of the solids in sewage.

"The Live Earth Bed System" has been adopted by the Alberta Government in connection with the drainage of Ponoka Asylum. The system has created no little interest in the Province, especially as it has had the strong backing of the Provincial Board of Health. We have been informed on several occasions that engineers have had difficulty in getting plans passed by this authority unless such plans are in line with this system.

It is a somewhat unique position for any central authority having control over stream pollution to dictate or attempt to dictate as to the particular method of sewage disposal to be adopted by municipalities. We have always understood that expert authority is inclined to agree that there is no one system of sewage treatment which will meet all local conditions, and that it is only after a study of the particular conditions appertaining to a district that it is possible to define the system which will give the required efficiency. This is not, however, the policy of the Provincial Board of Health of Alberta, as is evident by the following letter, signed by R. B. Owens, the advising engineer to the Board. The town of Macleod, Alberta, having determined to treat its sewage before discharging into the river which eventually forms the water supply to Lethbridge, etc., further down stream, addressed a letter to the Provincial Board of Health, asking if the government had yet come to any conclusion with reference to "The Live Earth System."

This is the reply which the Provincial Board sent on:—

[Copy.]
Dated March 15th, 1912.

G. H. Altham, Esq., City Engineer, Macleod, Alta.:

Sir,—I am in receipt of your letter of the 11th inst.

The Provincial Board of Health are very well pleased with the showing made by the Live Earth Bed system installed at the Ponoka Asylum. The latest report, dated March 7th, from the general building foreman on the Ponoka Asylum works is as follows:—

"The amount of solids now distributed over the face of the slates is about fifty per cent. less than it was the first of December. This alone shows an increase in efficiency of more than 100 per cent. now in comparison with the same time two months ago.

"The temperature in the building has been very even, never ranging over ten degrees of a variation during the winter. Our lowest inside temperature was 36 and our highest 46, while the outside has ranged from 47 below zero to 46 above zero. There is always two degrees difference between the inlet and outlet of the tank."

This system can be constructed for much less than any other; it can be operated for less than any other; every other system will freeze solid in winter in the filter portion; it is the only system odorless in its operation; it fulfils the requirements of the Provincial Board of Health, and the certificate that it can be constructed, operated and carried out without injury or danger to the public health will be granted to those installing it. The sterilization process used in connection with it ensures the total destruction of pathogenic organisms. There is practically no sludge, which is practically the whole of the solids in sewage, to be pumped out and removed, a filthy and costly job, as is the case in others such as, say, the proposed Lethbridge plant. What more could you wish?

The proposed Lethbridge plant, on an old, out-of-date system, is to cost $63,522, and is supposed to give an effluent free from pathogenic organisms, but it will certainly leave practically the whole of the solids to be dealt with by pumping out and drying in the atmosphere, thus creating a serious menace to health, whereas my system could be installed in Lethbridge for less than $40,000, and would give an effluent free from pathogenic organisms and would leave practically no sludge to be dealt with.

I unhesitatingly recommend the Live Earth Bed System for Macleod.

Messrs. Dutcher, Maxwell & Co., Civil Engineers, who are now installing a sewage disposal plant, etc., in Camrose, are making a speciality of sewage disposal, and should you feel that you would like a firm of consulting engineers to help you out in this work, you communicate with them. Their address is Camrose.

I am, Sir,
Your obedient servant,
(Signed) R. B. Owens.

From the above letter it would appear that the Provincial Board of Health of Alberta has come to the definite conclusion that the "Live Earth Bed System" of sewage disposal is the only one on earth which deserves any consideration, and is, further, the only system which warrants a certificate from the Board that it can be constructed, operated and carried out without injury or danger to the public health. This Board of Health appears to have finally solved the much-discussed sewage disposal problem upon the strength of a single experiment made at Ponoka Asylum, and apparently upon the report of the general foreman, dated March 7th, 1912.

We know that up to March 15th, this year, no chemical or bacteriological examination of the effluent from the Ponoka Asylum had been made by the Provincial bacteriologist attached to the Board of Health.

We know that even up to May 23rd, this year, an examination of two samples of the treated and untreated sewage at Ponoka Asylum showed results for removal of solids as follows: Sample No. 1—Untreated sewage, 603 parts per million of suspended matter; treated sewage, 570 parts. Sample No. 2—Untreated sewage, 500 parts per million of suspended matter; treated sewage, 448 parts per million.

It will be noted, however, that the remarkable letter to Macleod above quoted is signed on behalf of the Board of Health by the patentee and inventor of this system.

Two independent examinations and reports have been made with reference to the Ponoka Asylum plant, one by Mr. Child, the late City Engineer of Calgary, dated April 17th, 1912, and another by Mr. T. Aird Murray on behalf of the Bureau of Public Health, Saskatchewan Government. These reports, published in this issue, will be read with interest, and generally bear out the remarks and criticism which *The Canadian Engineer* thought fit to make in the 1910 issues referred to.

TORONTO AND HER SIX MILLION DOLLAR WATER BY-LAW.

A by-law for the provision of $6,000,000 for an additional water supply for Toronto is one of the items to be voted on by the citizens on the first of January. The Board of Commissioners, who reported a few months ago on Toronto's water supply, emphasized the necessity of an additional and alternative supply to the present system now operating on the Island.

The plans, as outlined by the Commission, for which funds are now being asked, contemplate the establishment of the duplicate system on the heights at Scarboro, about twelve miles east of the Island plant.

The Scarboro plant, if installed, will cost about five and one-half million dollars, and will give an additional capacity of sixty million gallons per day.

The city is voting at the same time, on money by-laws for other purposes, with a total of six million dollars. The present state of the money market is such that the prospects for floating twelve millions of bonds this coming year are rather dubious.

Before the citizens are asked to provide the money for this duplicate system, they must be assured that the very best location has been picked for the plant, and that adequate returns in the way of an abundant supply of pure water at the lowest possible cost will be secured.

Is the report of the Commission, recommending the location of the new plant at Scarboro, the solution of the problem? Are the public satisfied that the conclusions of the experts as outlined in their reports, are justified? In next week's issue we hope to deal with some features of the report which have been overlooked.

SPELLERIZED PIPE.

Spellerized pipe has been on the market for some time, but no explanation has heretofore been offered as to what the process consisted in. The method is now explained by the National Tube Co. as follows: Spellerizing consists in subjecting the heated bloom to the action of rolls having regularly shaped projections on their working surface, then subjecting the bloom while still hot to the action of smooth-faced rolls, and repeating the operation, thereby working the surface of the metal to a uniformly dense texture, adapted to resist corrosion, especially pitting.

This process is, of course, of most service on 4-in. pipe, or smaller, because of the thin walls. The larger sizes, because of their thickness, do not require so much extra work of this character.

REPORT OF MR. CHILD, CITY ENGINEER, AND DEPUTATION OF CITY COUNCIL AFTER VISIT TO SEWAGE WORKS AT PONOKA

COPY.

Dated Calgary, April 17th, 1912.

City Commissioners,
Calgary.

Gentlemen,—Re the live earth system recommended by R. B. Owens, B.A., sanitary engineer for the province of Alberta.

This system of dealing with sewage appears to be adapted entirely to the retention and decomposition of the solid matter in sewage and takes no cognizance of the purification of the sewage liquid.

The system consists of a series of tanks, generally three in number, as illustrated by a plan submitted by Mr. Owens. The first two tanks are simply rectangular receptacles filled with layers of concrete slabs. The third tank is a rectangular receptacle for holding the liquid sewage after it has passed through the first two tanks. In the last tank provision is made for disinfecting the liquid sewage by means of the addition of chlorine.

The theory upon which the first two tanks is based is apparently the well-known attraction of matter to matter, and it is held that the concrete slabs attract the solids from the sewage which settles on the surface of the slabs and then gradually undergoes putrefaction until it becomes like ordinary earth. The essential difference between these tanks and ordinary sedimentation tanks exists in the adoption of the concrete slabs producing a greater surface area on to which the solids may settle. I understand that the system has been put forward in England by Mr. Dibden, who uses layers of slate instead of concrete slabs, and that in 1902 the Massachusetts State Board of Health carried out several exhaustive experiments with tanks similarly constructed filled with layers of slate about a half inch apart. Quoting from the State Board of Health, I find as follows: "The effluent was never of good quality. During May and June anaerobic conditions were noted and later became strongly marked and the experiment was discontinued. The filter lost open space rapidly and showed signs of choking." Mr. Owens claims that the action is aerobic and not anaerobic.

It is generally reported in England that the system has gained no ground, as the beds invariably choke and are difficult to flush or clean. The system of sludge removal, as now being adopted, appears to be based upon an entirely different process from that which is adopted in the concrete or slate bed systems. It appears to be recognized in all the newer forms of tank that the chief aim should be the immediate removal of the putrefying sludge from contact with the flowing sewage. This is exemplified in such forms of tanks as the Emscher or Imhoff types, the Traver's tanks and the forms as adopted at Lethbridge. With the slab system the liquid sewage must pass over the surface of the decomposing sludge and in this way much of the finer matter in recollected and the products of decomposition such as the sulphides, etc., are carried away with the liquid. Thus there is produced a septic effluent which it is acknowledged is most difficult to purify or disinfect. In fact, there is little essential difference between this form of tank and the old septic tank. It is simply a septic tank filled with concrete slabs. Mr. Owens claims that the tanks are essentially contact beds, and this form of tank has been shown to be simply a septic tank when it stands full of sewage and the air driven out.

Apart from the question as to whether the tanks are based upon a good working principle or otherwise, they are not suited to conditions at Calgary. Gravel here of any size and quantity is available for filtering purposes, and would be out of the question to substitute for gravel expensive concrete slabs, of which an enormous quantity would be required.

While the system may be suitable for some small installation it certainly does not lend itself to any large plant where extensive contact beds would be required.

One of the main difficulties in connection with the system appears to be the difficulty of removal of the settled sludge between the concrete slabs. While this may be possible in a small tank, it appears almost impossible in any large tank consisting of a huge body of such slabs. The slabs, once being put into position, it would be most expensive to remove them and reset them, and it does not appear possible that any working principle of flushing can be adopted for a large area.

All the newer systems of sewage disposal with which I am acquainted appear to aim at the immediate and automatic removal of sludge by means of slow velocities and secondary sludge storage receptacles, into which the precipitated sludge at once gravitates.

Another and very vital objection is the amount of fall requisite. Mr. Owens' plans show 15 feet. The tanks as proposed at Lethbridge for the removal of solids require only 1 foot, the difference between inlet and outlet weirs.

From personal observations obtained whilst visiting the Ponoko asylum sewage disposal works, one is able to deduce the following: The works, according to Mr. Owens' own statement, is overtaxed four times its capabilities, that is to say, instead of 300 people accommodated these works would be overtaxed with anything over 75 persons. The cost of the system was $6,236.10. Proportioning this to a city of 75,000 the cost would be $6,236,000.

The noticeable features in connection with the Ponoka system are, that an objectionable odor is very apparent, caused by putrefactive process in connection with the sludge retained on the slabs, and that the effluent is far from clear. The discharge is into an open ditch extending some 300 yards, and depositing onto a ploughed field. The bottom and sides of this trench are lined with slime and the effluent itself has a distinct odor. This, no doubt, is accountable to the system being overtaxed, still, without filtration as a final treatment before discharging into our rivers, there are grave doubts as to the health authorities allowing this city to adopt a system of this nature without filters, which, after all, are the essential points of sewage disposal works.

Respectfully submitted,
[Signed] J. T. CHILD,
City Engineer.

REPORT UPON PONOKA ASYLUM PLANT BY T. AIRD MURRAY TO THE BUREAU OF PUBLIC HEALTH, SASKATCHEWAN

July 26th, 1912.

Dr. M. M. Seymour,
Commissioner of Health,
Regina, Sask.

Dear Sir,—You informed me on the 19th of April last that you had received enquiries as to whether you would accept, as satisfactory, proposals to install schemes of sewage disposal within your provincial jurisdiction of Saskatchewan similar in principle to a scheme recently installed under the auspices of the Provincial Board of Health of Alberta in connection with the government asylum at Ponoka. I informed you that I had no personal actual knowledge of this plant, but that I had seen plans and a description of it, but had not seen any data referring to its working efficiency.

You commissioned me to proceed to Alberta, visit the plant at Ponoka asylum and confer, if possible, with the authorities of the Provincial Board of Health with reference to this matter and report direct to you upon this plant.

I inspected the plant in question on the 22nd of April, and interviewed the provincial bacteriologist at Edmonton on the 23rd.

I took two samples of the sewage, one representing the raw sewage influent as it entered the works, and the other representing the sewage effluent as it left the works after treatment. These samples I divided, leaving a portion of each with the provincial bacteriologist, and the other two portions I had sent direct to my analyst in Toronto. I considered this a proper course to pursue, as I take it, that more accurate results would be obtained by immediate analysis at Edmonton than I could obtain after sending samples over so long a distance occupying the considerable period of time between sending off from Edmonton and arrival at Toronto. The provincial bacteriologist promised to examine the samples left with him and report to me the nature of the results obtained. He has done so, and a copy of his results are appended.

The System of Sewage Disposal as Installed at Ponoka Asylum.

I met at Ponoka the foreman in charge of the works, who kindly went over them with me and freely gave me all the information which he could. It appears that the system of disposal has only been in vogue for about 10 months; it treats of the sewage, which is purely domestic, from the asylum, representing about 300 people, with a normal discharge of about 24,000 gallons per 24 hours, or 80 gallons per head per day.

The location of the disposal works is a considerable distance from the Asylum buildings, and is upon falling ground forming an ideal site for treatment of sewage upon the modern biological methods, there being ample fall. The character of the site presents ideal conditions which are not often met with in the prairies, as the main difficulty is, generally, lack of fall.

The plant consists of duplicate primary contact beds, each with a capacity of 1,000 gallons, rectangular in shape, 19 feet 9½ inches x 11 feet 11½ x 3 feet deep, and one secondary settling tank of 1,000 gallons capacity. The sewage first enters the primary tanks and is held there for a period of about 4 hours, when a valve is operated and the sewage allowed to flow into a channel pit and then into the secondary or final settling tank. From the latter tank the effluent discharges into an open channel and terminates in a hollow forming a small slough, from which it appears to percolate and evaporate. The soil is sandy and very friable, and will probably continue to absorb sewage effluent for some considerable time.

Laid longitudinally in the entrance channel to the secondary tank is a perforated zinc pipe which is periodically filled with chloride of lime, the object of this is, that the flowing sewage may absorb chlorine from the lime and be disinfected.

The whole of the works are extremely simple and compact and are housed in a roofed building.

The cost of installation was reputed to be $6,236.10, and the intended capacity designed for 300 persons, representing a sewage discharge of 24,000 gallons per day. The plant has, however, been found to be too small and incapable of producing satisfactory results, and work was in progress for doubling the capacity of the system and building similar tanks alongside the present ones.

The chief feature in connection with this plant is the adoption of what is called in England "Dibden's Slate Bed System"; the only difference being that instead of slates, concrete slabs are used. The concrete slabs are laid in the tanks in layers. Each slab is 24 inches x 12 inches with square openings 8 inches x 6 inches in each slab. Concrete rests are placed between each layer to keep the slabs apart. In the primary tanks the slabs are 4 inches apart, and in the secondary tank 2½ inches apart.

I understand that the system has been patented in Canada by the sanitary engineer to the Alberta Provincial Board of Health, under the name of "The Live Earth Bed System."

I have read certain descriptions and explanations of the working of the plant sent out by the Alberta Provincial Board of Health, and it is claimed chiefly that the presence of the slabs in the tanks will effect the retention and collection of the solids contained in the sewage, which will be transformed into some substance resembling live earth, because of the great number of worms and other living organisms which will be germinated in the retained solids. It is claimed that these organisms have the faculty of turning the solids into an inoffensive material and that the sludge difficulty is thus obviated. I suspect that what is really meant is that the sludge undergoes very rapid decomposition and is charged into a humus state resembling the thoroughly septicized material resulting from a septic tank or tanks of the Emscher design, where decomposition of the sludge is aimed at.

I was informed that no analyses of the effluent had been made up to the date of my visit, and no actual data existed as to the results, but that it was acknowledged that the capacity was too small for the amount of sewage under treatment.

On entering the building in which the tanks are located, the odor peculiar to septic tanks, when covered in, was at once apparent. In the primary tanks the top slabs, which only were visible, were well covered with sewage solids. The secondary tanks presented a sewage which appeared to be highly charged with solids also. The ditch leading away from the tanks was very black with sewage solids and slime, and the slough at the terminus of the ditch was simply a lagoon of sewage solids. For all practical purposes the tanks did not appear to be doing anything more than might be expected from an ordinary septic tank and the effluent had all the appearance of an ordinary septic tank effluent. Owing to the lack of any collected data relating to periodic examination of the raw sewage and effluent, nothing more can be said as to efficiency in this particular instance, except that the samples which I personally took showed distinct signs of septic action, but that owing to distance of travel they were of little value for basing conclusions.

With Reference to the System in General.

The system is termed by the Alberta Provincial Board of Health to be essentially one of contact beds, with laminated concrete slabs in lieu of ordinary filtering material. The action of filling the beds and retaining them full of sewage for a period of time excludes all oxygen, and tends to rob the sewage of any dissolved oxygen it may originally contain. The action is essentially septic and not one of oxidation as with the percolating filters, where air is always present. It is universally acknowledged that the percolating system has decided advantages over the contact system, see Dunbar's "Principles of Sewage Disposal," fifth report of the British Royal Commission on sewage disposal and recent research work of the Lawrence Experiment Station, Mass.

The tanks may be described as merely septic tanks with the exception that they are periodically emptied, when oxidation may take place in connection with the matters retained on the slabs. The object of the system cannot be to obtain a non-putrescible liquid effluent, as such cannot be done without oxidation.

I do not consider that there is any efficient or economic reason for the use of the slabs, which add a very great expense to the tanks, and must in the case of large installations make it difficult to clean out the tanks. I believe that just as satisfactory results are obtained by such tanks as the septic tanks at Moose Jaw and Indian Head which are being superseded by more modern methods. The method of disinfecting the sewage by means of a pipe filled with chloride of lime and laid in the flowing sewage is too crude and so obviously inefficient, that it is not necessary to remark further with regard to this unless to say that I was informed that the pipe was freshly charged with the lime once a week, and it is apparent that the whole of the disinfecting efficiency of the lime must be lost almost immediately it came into contact with the sewage liquid. Except for about one half-hour during the week this disinfecting process must be valueless.

Assuming the present installation to be sufficient for 300 people (it is acknowledged that it is not) then the cost per head for sewage treatment is over $20. At the same proportion the cost for 4,000 population would be $80,000; and for 10,000 population $200,000. As the system requires doubling in capacity it really works out at $40 per head. Efficient sewage disposal consisting of removal of solids, putrescibility and disinfection should not exceed $5 per head unless under very exceptional circumstances. It may be pointed out that small installations cost more per head than large ones, at the same time with the ideal situation as presented at Ponoka, it is safe to estimate that an efficient system of sewage disposal could have been installed at a cost of under $3,000. In fact, the Northumberland and Durham Counties have a system of sewage disposal in vogue consisting of sedimentation, sprinkling filters, and slow sand filtration for removal of bacteria for a similar institution at a cost of less than $2,000.

I may conclude by stating that I cannot recommend the system as an efficient one from what I saw at Ponoka or from what one would naturally expect as results from such a system. It does appear apparent that the system even as one for the treatment of solids is not in accordance with modern recognized sedimentation tanks. The principle which is being adopted very generally in connection with sedimentation tanks and removal of solids is to separate immediately precipitated solids from all contact with flowing sewage, so that the flowing sewage may not come into contact with solids which are undergoing decomposition. The opposite of this principle is attained by the Ponoka plant.

Allow me to sum up what I consider the various points of objection to the "Live Earth System" as inspected at Ponoka Asylum:

(a.) That it is only a system for removal of solids and not for treatment or putrification of the liquid sewage.

(b.) That the liquid sewage is certain to be putrescible and septic in character owing to, 1st, no oxidation, and, 2nd, contact with the decomposing sludge.

(c.) That even if a large proportion of the solids are retained by use of slabs inserted in the tanks, that there are other less expensive methods of retaining a sufficient proportion of the solids to allow of the remaining liquid sewage being efficiently dealt with by means of oxidizing filters.

(d.) That even if the retained sludge undergoes decomposition so that it resembles earth of humus, that there are other methods more simple and less expensive of obtaining similar results (as per experiments at Chicago and elsewhere).

(e.) That the system does not lend itself to efficient disinfection, and that disinfection is more efficient and less expensive when an oxidized effluent is obtained.

(f.) That similar systems have been tried and experimented with by the Massachusetts Board of Health and others and have failed in results.

(g.) That a similar system has been tried in Great Britain, but that recent reports are not of a favorable nature unless with very small installations, and that such systems in Great Britain do not pretend to do anything more than treat with the solids contained in the sewage and are not for the final purification of sewage.

(h.) That the cost, owing to the provision of the slabs, causes the system to be prohibitive.

(i.) That the great amount of fall required by the depth of the primary and secondary tanks would in most localities prohibit its use unless the sewage was pumped.

Your obedient servant,

(Signed) T. AIRD MURRAY,
Consulting Engineer.

* * * *

COPY.

May 23rd, 1912.

Mr. T. Aird Murray,
Consulting Municipal & Sanitary Engineer,
303 Lumsden Building, Toronto, Ont.

Dear Sir,—I have yours of the 17th inst., and am glad to furnish you with the results shown by the two samples of sewage which you left with me.

Estimation of the suspended matter gave the following:

No. I. (Influent).

Unfiltered	603 parts per million.
Filtered	570 parts per million.
Difference	103 parts per million.

No. II. (Effluent).

Unfiltered	500 parts per million.
Filtered	448 parts per million.
Difference	52 parts per million.

As the capacity of the beds at Ponoka is, I understand, being greatly exceeded by the daily amount of sewage the above figures cannot be regarded as a test of the work of this type of bed in the removal of suspended matter put through them. This deficiency, however, I believe is being made good by adding more beds.

I shall be very pleased to have the promised copy of your report.

Yours very sincerely,
(Signed) D. G. REVELL.

CANADIAN NORTHERN MAKES OFFER TO LONDON.

Judge Phippen, Colonel Davidson, and Engineer McCrea, representing the Canadian Northern Railway, have made a definite offer in regard to the leasing of the London and Port Stanley road, which is owned by the city.

They offer to lease the road for 99 years at $20,000 a year for the first ten years, and $25,000 a year for the balance of the time. They agree to run a line of steamers to Port Stanley, and make London a divisional point, with shops that will employ from 150 to 250 men. They promise also to place London on their main line

Michigan Central Railway and Pere Marquette will be given running rights over the system and summer excursions to Port Stanley.

CONSTRUCTION OF CONCRETE-LINED WATER TUNNEL.

The municipal aqueduct tunnel for the city of Santa Barbara through the Santa Ynez mountain range in California is nearing completion. The tunneling, now practically completed, involved many difficulties in the form of poor rock and large inflows of both water and inflammable gas. The tunnel construction was begun under contract and abandoned when about half finished. The following account of how the work then was taken up by the city directly and carried to a successful conclusion under force-account methods is from a paper presented recently before the League of California Municipalities by Mr. Lee M. Hyde, supervising engineer.

The peculiar topographic conditions surrounding Santa Barbara have presented difficult barriers to water development and have demanded expensive and drastic treatment for solution. Paralleling the coast for a distance of 75 miles is the Santa Ynez range of mountains, leaving between it and the ocean a narrow strip of tillable lands. This range at the crest has an average height of from 3,500 to 4,000 ft. elevation, but on account of the steep slope southward affords a very small area of watershed. The creeks are in consequence short, having very little summer flow and on account of their severe grades prohibit reservoirs for impounding winter flood waters.

However, the early water supply was gained by diverting water from two creeks north of the city and later by driving a tunnel 5,000 ft. deep into the Santa Ynez range. This first tunnel is located about 4 miles west of the tunnel now under construction and was projected merely for the purpose of developing water in the Santa Ynez mountains. During construction the constant tapping of new water strata maintained a very good flow, but as soon as work ceased the saturative power of the formation was reduced to a small normal output which would soon be insufficient to meet the city's needs. Moreover, the lowering of the water plane in the mountain depleted the surface flow and the city was soon confronted with legal complications brought by riparian owners on the creeks affected.

It was at this time that public officials, realizing that the city's growth was being jeopardized by an insufficient water supply, called into consultation Mr. J. B. Lippincott, of Los Angeles, who has since been consulting engineer on Santa Barbara's water supply. The result of Mr. Lippicott's investigation was the acquiring of two reservoir sites in the upper Santa Ynez River basin below a water-shed of 210 square miles, the rights of way for a tunnel through the Santa Ynez mountains and the purchasing of power plant locations immediately north of the city.

The city immediately prepared for the construction of the tunnel 19,560 ft. in length, and contracts were let in accordance with the provisions of the city charter. The contractors drove a little less than 50 per cent. of the tunnel and were then forced to relinquish their contracts by the city Water Commissioners and Council. Their inability to prosecute the work properly, Mr. Hyde states, was partially the result of adverse conditions of formation, gas and water encountered, which had not been given sufficient weight in preparing their estimates, but for the most part was the direct result of inefficient equipment. For economical and rapid progress there must exist a high state of organization, both as to equipment and labor forces, and to this end the best of mechanical appliances should be purchased and duplicate plants installed, to eliminate delays from breakdowns of machinery. Such delays are expensive and have a discouraging effect on the workmen. To secure and retain the most energetic and skilled workman the camp should provide clean boarding houses, comfortable and sanitary quarters and good change rooms.

The city after taking over the work was occupied for some time in the installation of equipment, both surface and underground, and also in remodeling and adding to the camp quarters. On the north portion of the tunnel poor ventilation had resulted in a fungus growth vigorously attacking the timbers, causing dry rot, and it was necessary to line immediately with concrete about 2,600 ft. The timbers, in a great many places where heavy ground was being supported, were dangerously weak, and great care was necessary to protect the workmen as well as the tunnel. In certain portions, smaller sets, reinforced by sprags, were put in and the weakened 8 x 8-in. sets removed. In many places it was also necessary to centre post the caps. Under ordinary conditions the original lagging was not removed, although there were places where the fungus had caused such a severe rot that the ground had broken through. In these places the lagging was replaced and such additional timbering done as was necessary to withstand the ground weight during concreting.

The tunnel section is 6 ft. wide at the bottom, 4 ft. 6 in. wide at the top and 7 ft. high in the clear. The concrete forms, therefore, required a design occupying as little space as possible. The forms consisted of steel ribs placed on 5-ft. centres which supported 2-in. lagging. These ribs were made of 5-in. channel steel with 1½-in. web and were bent to conform with the tunnel section, being cut in two in the centre of the arch and the two halves joined together by an iron strap and four bolts. Form setting and concreting followed very closely the timber repair. The steel ribs were set on wooden foot-blocks and at the bottom were braced from the track rails. They also had additional braces at the spring line and arch centre, only these braces were to the rib and back of the tunnel. Before the forms were set a trench was excavated on each side of the tunnel to solid formation for the foundation. The width of this excavation depended on the thickness of wall to be placed, although it was always from 6 in. to 2 ft. wider than the wall.

When ready for concrete the bottom board behind the steel rib was not placed lower than the grade line of the tunnel floor. This allowed the concrete to fill the foundation excavation outside of the forms. The concrete was delivered to the shovelers in a specially designed watertight galvanized-iron box, built on a flat car. This box was 3 ft. wide, 14 in. deep and 9 ft. long with an outward slope at each end of 1 to 1, which facilitated shoveling. This car also was used to remove the foundation trench cleaning, being hosed out before again filling with concrete. After the foundation was in the walls were carried up to a point that left about 14 in. of key. Then the lagging was placed over the arch and the key of 5 ft. in length rammed from the end. A stiffer mix of concrete was used in the key than the walls. The average thickness of concrete lining was from 6 to 8 in., although in some of the loose or swelling formations the lining was heavily reinforced with steel and had a thickness of 12 to 20 in. It was in these sections and where temporary sets were used that centre posts and sprags were placed.

In order to get a good uniform thickness of lining, it was necessary to take out sets of 10 x 10 in. and 12 x 12 in. or trim them down to one-half or even one-third the original size. The sprags were placed above the cut to be made and supported the weight until the weakened portions could be covered with concrete. If necessary, these sprags could be concreted in and removed after the forms were taken down. Considerable precaution was taken when concreting a section where the water inflow was a perfect rainstorm.

Sections have been concreted where the flow of water in 5 ft. of tunnel was 25 or 30 miners' inches. In these places wood strips of ½ or 1 in. in thickness were nailed to the lagging of the timbers and then covered with sheets of tin. This tin would entirely cover the section and the water was conveyed down the sides to the foundation trench. Here pipes were placed to carry the water through the concrete wall. Ordinarily, a hole was cut through the timber lagging and the pipe placed so the intake was on the outside. Then a rich concrete or cement filled the trench above the tin and forced the water through the pipes.

The average cost of placing 4,614 ft. of concrete lining in the north portion of the tunnel was $9.79 per foot. This included a teaming charge from Santa Barbara to the north portal of $3.75 per barrel of cement and $28.12 per 1,000 ft. on lumber. Gravel from the Santa Ynez River bed was hauled about three-quarters of a mile. The divisions of cost were as follows:

Cost of Lining Per Foot of Tunnel.

Administration and labor	$4.63
Cement	3.64
Forms	.18
Sand and gravel	.24
Miscellaneous supplies	1.10
Total	$9.79

Santa Barbara's tunnel has presented many expensive and difficult problems. The Santa Ynez range generally is a highly stratified shale and sandstone alternating from one to the other in layers of a few feet to several hundred feet in thickness. The tunnel attack is at a strike and dip, ranging from 75 to 85 deg. The formation at contact points is ordinarily quite shattered and this loose condition is aggravated in water-bearing sections. When the north portion had been driven to a depth of 4,800 ft. from the portal a highly inflammable gas in large quantities was encountered. This gas section extended for a continuous distance of 1,300 ft. The formation for the first 700 ft. was shale, followed by 400 ft. of oil sand. Here the formation was badly faulted at its contact with the shale, which was the formation to the end of the gas section.

The quantity of gas at first was not alarming, although as a safeguard against accident safety lamps were used to test the heading after each blast. Small accumulations of gas located in the higher portions of the tunnel would then be burned out by touching them off with a torch. This done, the seepages would be lighted and if the inflow was sufficient would maintain a constant flame during the next shift, being extinguished by the next blast in the heading. As the heading neared the oil sand gas was encountered in larger quantities, and finally when this formation was opened up a larger amount of gas accumulated in the tunnel immediately following the blast and was accidentally exploded by the workmen. The force of the explosion was terrific and those not severely burned were hurled along the tunnel. Besides one killed, all the men were seriously injured. This was an exceptionally large quantity of gas, being about 25,000 cu. ft., and had been released by opening up 5 ft. of ground in the heading. It was not the seepages of gas in the tunnel that gave trouble, but the unknown quantity that was released by advancing the heading.

To guard against and safely dispose of this unknown inflow, Mr. Lippincott and Mr. Hyde placed a system of electric arcs in the tunnel which were used to ignite the gas after firing a round in the heading. The arcs were specially made, being designed to withstand the concussion of the blasts and explosion of gas. When the round was ready to fire these arcs were placed in high points along the tunnel about 200 ft. apart, the first one being located about 150 ft. back of the heading. The round was then fired and the crew retired to the portal. A fire boss and helper then took charge of the tunnel and 4 hours were consumed in testing before the next heading crew went on shift. The fire boss waited for about 30 min. after the blast before turning an electric current into the arcs from an outside switch. This wait allowed a better chance of gas removal by the blowers, which were always reversed to exhaust from the heading after blasts. An ammeter was used at the switch to indicate whether the arcs responded or not, and all the arcs were connected in series.

After obtaining results of arcing from the portal the fire boss and helper advanced to another arcing station 3,500 ft. from the portal. Here the electricity was again turned into the arc circuit. If there was no gas explosion the fire boss with a safety lamp tested the entire tunnel ahead. If no large pockets were discovered he returned to the station, where he again switched the electricity through the arcs. This time with the arcs burning, he returned to the heading and placed torches at intervals of 100 ft. through the gas section, which were kept burning during the next shift.

Ordinarily the muck pile would burn like coal for some time, and on one occasion was ablaze for fourteen hours. Drilling and firing a round of holes was often quite spectacular and required a great deal of care. As soon as the hole was drilled the gas from it would be lighted, sustaining a good sized flame. I have seen as high as six out of eight holes on the top round burning like blow torches. Before loading a round the holes had to be cooled. For this purpose two lines of water and two of air, each under 100 lb. pressure, were turned into them. This extinguished the flame, and as soon as the accumulation of gas reached a point 20 or 30 ft. back of the breast it was exploded and then immediately put out at the holes again by the air and water. This operation was repeated until the holes were cooled sufficiently to load and were then immediately fired. Driving through the gas section using the sparking devices was comparatively safe and not very expensive. Two heading shifts were maintained, and aside from the two 4-hour periods of fire boss shifts the work was uninterrupted.

The north portions of the tunnel required timber for about 71 per cent. of its total length, and although spiling and breast-boards were necessary in a great many places, most of the timbered sections offered no particularly severe problems on account of the absence of water. Good average progress was maintained by city force account during the entire work, and one very good record was made when the heading was advanced 337 ft. in thirty days by two drilling and three mucking shifts. About 48 per cent. was timbered.

After passing through the gas section, water was continually encountered until the inflow was taxing to their capacity the pumps and water columns. This meant the installation of larger pumping equipment or abandonment of the tunnel. As the distance to be driven did not justify the expense and moreover could be easily accomplished from the south side, the latter course was followed. Before abandonment the tunnel was concreted in sections where the ground was loose and heavy. The equipment was then transferred to the south portion of the tunnel and all work has been prosecuted from this end since.

The cost of driving 2,779 ft. of the north portion was $25.55 per foot, including the cost of timbering 1,736 ft. The distribution of this cost was as follows:

Cost of North Tunneling Per Foot.

Administration	$ 1.68
Labor	10.90
Power	3.81
Explosives	1.30
Timber	2.25
Track and pipe	1.76
Miscellaneous supplies	2.94
Drill parts	.62
Bonus	.20
Total	$25.55

The south portion of the tunnel differs very little in formation from the north, only larger bodies of sandstone have been penetrated. The sandstone contains crevices, and large water courses have been opened up in this formation. This blocky ground is the saturated portion of the mountain, and the intervening shale bodies act as the sides of what might be termed vertical reservoirs. The average flow for the past two years has been from 350 to 400 miners' inches.

In passing through sandstone, particularly after the tunnel had gained a depth of about 1,000 ft. vertically from the surface, the pressure of water in drilled holes has at times been very severe. Instances where drill steel was forced tight against the machine, requiring two or three men with Stilson wrenches to release it from the chuck, were frequent, and jets of water shooting down the tunnel in a horizontal line for a distance of from 25 to 75 ft. are not uncommon. Some of the main crevices yielded a flow when first tapped of from 75 to 150 miners' inches of water, and one main water course released a flow of 350 miners' inches. This drained down rapidly and within a week had diminished to about one-half this volume.

In driving from one point of contact to the other in sandstone the water follows the heading to a large extent and is a general handicap to the work. In drilling rounds, extra holes are required to release the pressure of water from the ones to be loaded. Even then it is necessary to load the holes by inserting stick after stick without tamping and then wedging at the collar. Mucking and track laying is also a task on account of the shifting sand which collects along the floor of the tunnel and over the rails for hundreds of feet back of the heading. All of the large water strikes were made in loose caving formation and greatly increased the difficulties of timbering problems. Through these sections spiling was necessary, and sometimes breast boards.

The large volume of water constantly flowing through the tunnel has had a severe effect on transportation of muck trains, as the track is always covered with water from 8 to 12 in. or more in depth. It is difficult to do repair work on the track, and besides floaters are being constantly encountered, causing wrecks. The depth of water is also a hardship on the motor cars, causing shorts and grounds in the fields, armatures, resistance and wiring, which have to be continually repaired. Water has been the most embarrassing feature of the construction. However, good progress has been maintained, the heading having been advanced 439 ft. during one period of thirty days, the average progress by city force account in the last 4,800 ft. being about 275 ft. per month at a cost of $26.16 per foot.

On April 7 of this year one of the timbered sections caved in at a point 7,360 ft. from the portal. The total collapse of the entire string of timbers 33 ft. in length occupied but a short time, and the workmen at the heading 4,500 ft. beyond had barely room to escape by the time they reached the caved portion. Special mention is due Frank Fizer for his presence of mind and heroic action in notifying the workmen of their danger. Mr. Fizer was acting as motorman and discovered the case on his outward trip. On account of breaking a trolley pole it was necessary for him to wade through water to the heading. A short time after the crew reached the portal side the tunnel filled with muck. The total water flow of the tunnel at this time was 395 miners' inches, of which about 300 miners' inches was coming into the tunnel on the heading side of the cave. This water was immediately shut off by the impervious nature of the muck pile which was mostly a mixture of soft clay and running shale. In a few hours the large volume of water had entirely filled the tunnel between the cave and heading and then on account of the small displacement necessary to resaturate, the formation above gained headway rapidly and soon exerted a pressure against the muck pile. This carried the muck pile toward the portal of the tunnel and forced the workmen back. The water then would gain a greater pressure, which would again overcome the resistance of this muck pile and move it down the tunnel. This process continued until the tunnel was filled with muck for a distance of 437 ft., at which point further action was blocked by two bulkheads, a temporary wooden one to protect the workmen while the permanent concrete bulkhead was placed.

By placing a pressure gauge on the compressor air line some idea of the pressure was gained during the early stages, but on account of the line giving way few readings were obtained. However, these showed a gain from 19 to 122 lb. per square inch in 14 hours.

A side drift was then projected around the caved and filled portion of the tunnel, and opposite the soft caved stratum was 100 ft. distant. At this point 12 x 12-in. timbers with 4 and 6-in. spiling and 3 x 12-in. breast boards were used. It was necessary to hold every inch of ground in place, as a slight movement might allow the terrific water pressure in the main tunnel to cause a general movement of the loose muddy formation, separating the two bores, and in this case the muck could very quickly slide into the side drift and duplicate the muck shifting process following the cave. The progress through this section was very slow, but the results obtained were most satisfactory. However, it was necessary to concrete this timbered section immediately after passing through the ground to insure safety.

The side drift was then advanced and turned toward the main tunnel again so the approach was at an angle of 41 deg. The side drift is 785 ft. in length, some of this distance being necessary to gain a location in the old tunnel where the formation was considered solid enough to tap through. When the side drift had gained a location that left 18 ft. of wall between the two tunnels the heading was stopped and preparations made for tapping the main tunnel. The formation was a tight and tough slate shale and was practically dry, but owing to its brittle nature was flaking off with loud, quick reports for the last three days before the tap on account of the water pressure, which was probably 500 lb. per square inch. In order that the attack might be at right angles with the main tunnel, a cross cut of 7 ft. in length, carrying a 3-ft. 6-in. bench, was made. The tapping holes, 11 ft. long, were drilled in this face. Four holes were drilled from a cross-bar. These were collared about 20 in. apart and brought together at the bottom. A pilot hole was kept 2 ft. in advance of these four to indicate the exact location of the main tunnel rib. When this was determined the holes then about 12 in. from the rib were charged with 50 lb. of 40 per cent. powder and fired. Fifty-foot fuse was used, which allowed plenty of time for the shift to get out of the tunnel. The results of the blast were particularly successful, the water being gradually reduced. The connection of the side drift with the main tunnel was then made and the clearing of the main tunnel to the heading started. The main tunnel has suffered somewhat on account of the action of the long storage of water, the full extent of which has not yet been determined.

Timbered and untimbered sections have been affected, and it will probably be sixty days before the heading is reached.

The cost of driving 6,215 ft. in the the south portion was $26.16 per foot, including the cost of timbering 1,075 ft., distributed as follows:

Administration	$ 1.55
Labor	12.15
Power	2.98
Explosives	2.35
Timber	.57
Track and pipe	1.41
Miscellaneous supplies	3.30
Drill parts	1.32
Bonus	.53

THE DURABILITY OF GROUTED GRANITE PAVEMENTS.*

By William A. Howell.

In the city of Newark, N.J., on November 1 there were 12.54 miles of completed grouted granite pavement covering 235,825 sq. yd., laid under public contract at a cost, including inspection and advertising, of $922,214. About 0.8 mile of this pavement has been in service three years and 3⅔ miles is at least two years old. The important part of the work of producing a satisfactory grouted granite pavement, with close joints, is the preparation and application of the grout mixture. In Newark the specifications for grouted granite pavements are those adopted by the Association for Standardizing Paving Specifications. The grout mixture must be at least as rich as one part of cement to one part sand; the exact proportions depend upon the hardness of the granite used, and this quality should be ascertained by experiment so as to produce a grout which will wear down uniformly with the granite.

The very hard granites are not well adapted to this type of pavement, but there is no question as to the durability of the grouting where comparatively soft granite is used and where the specifications are rigidly adhered to. Horses very seldom fall on grouted granite block pavement, even when the grades are moderately steep. The grouted granite pavements in Newark are wearing exceedingly well under heavy traffic, and even along street railway tracks the results are good. The New Hampshire granites appear to give the best satisfaction, for they are soft enough to wear down without polishing and becoming slippery.

To secure good grouted pavement of granite blocks, the following points should be kept in mind: Be sure the sub-grade is well rolled and all soft places eliminated. The concrete base should not be too rough and there should be a uniform thickness of 2 in. of sand under the blocks. The blocks should be carefully culled and well rammed. A small percentage of loam in the sand, not over 5 per cent., is desirable as a builder. The sand and cement should be mixed in the proper proportions, and the mixture should be continually agitated. The blocks should be thoroughly sprinkled immediately before grouting. Grouting should not be attempted during cold weather; good results are seldom secured after November 15 in the latitude of New York City. If grouting is done during very hot weather the finished work should be covered with ½ in. of sand and kept moist. Traffic should be kept off grouted pavements for at least seven days after completion. The use of a moderately soft granite, similar to New Hampshire granite, is recommended.

---

* Abstract of paper delivered before American Society of Municipal Improvements, Nov. 12-15.

FACTORY GROWTH IN WESTERN CANADA.

Some figures relative to factory growth in Western Canada are given and are of interest, showing as they do that real estate is not the only form of investment open to the residents in that section.

Manitoba.

(1910 Compared with 1905).

	Per cent.
Establishments: Increase	24
Capital: Increase	74
Employees: Increase	70
Salaries and wages: Increase	100
Value of products: Increase	90

Saskatchewan.

(1910 Compared with 1905).

	Per cent.
Establishments: Increase	116
Capital: Increase	77
Employees: Increase	125
Salaries and wages: Increase	170
Value of products, Increase	151

Alberta.

(1910 Compared with 1905).

	Per cent.
Establishments: Increase	142
Capital: Increase	432
Employees: Increase	241
Salaries and wages: Increase	265
Value of products: Increase	266

Manitoba.

The following tabulates the specific details:—

	1900.	1905.	1910.
Establishments	324	354	439
Capital	$ 7,539,691	$27,517,297	$47,941,540
Employees	5,219	10,333	17,325
Salaries and wages	$ 2,419,549	$ 5,909,971	$10,912,866
Value of products	$12,927,439	$28,155,732	$53,673,609

Saskatchewan.	1905.	1910.
Establishments	80	173
Capital	$3,973,075	$7,019,951
Employees	1,444	3,250
Salaries and wages	$ 721,875	$1,936,284
Value of products	$2,520,172	$6,332,132

Alberta.	1905.	1910.
Establishments	120	290
Capital	$5,545,821	$29,518,346
Employees	2,045	6,980
Salaries and wages	$1,167,107	$ 4,365,661
Value of products	$5,116,782	18,698,826

SUBWAY AND BRIDGE COSTS.

A reinforced concrete highway bridge spanning two railway tracks, waterproofed, paved with vitrified brick and designed for a moving weight of 100 lbs. per sq. ft. of floor area, or a 10-ton road roller, can be built for $1.65 per sq. ft. of floor, including the spans, supports and ordinary foundations, according to a statement made by H. N. Rodenbaugh, assistant engineer, Southern Railway, Atlanta, Ga., in a paper read before the Engineering Association of the South. Such a structure is only slightly higher in first cost than the typical steel girder bridge of similar capacity with a wooden floor, which costs about $1.50 per sq. ft. of floor area complete. A very satisfactory wooden Howe truss bridge of modern design has been built by one railway at a total cost of $45 per sq. ft. of floor area, and as between the latter two structures. Mr. Rodenbaugh very much favors the wooden bridge. Commenting on shallow floors, which are very common in subway design, he states that a typical open floor—that is, one having ties resting on steel stringers without ballast—will have a depth from base of rail to under clearance of about 3 ft. 4 in., and will cost about $1.20 per sq. ft. of floor area. A transverse steel I-beam construction with ballasted deck on flat plates will have for the same span a depth of 3 ft. 1 in., and will cost about $1.90 per sq. ft. of floor area. A transverse steel rectangular trough floor will have a depth of 2 ft. 10 in., and will cost about $2.50 per sq. ft. of floor area. The last two designs are assumed to have waterproofed floors with a minimum of 8 in. of ballast under the ties, the cost given being for the steel work only.

INCREASED PRODUCTION OF STRUCTURAL MATERIALS

Canada's mineral production includes these important and valuable structural materials:—Cement; clay products of various kinds, such as brick, sewerpipe and tile pottery, etc.; lime; sand-lime brick; sands and gravels; slate; and stone for building and other purposes, including granite, marble, limestone, sandstone, etc. No complete record of production of sands and gravels throughout Canada has been obtained, but statistics of exports are published. The statistics of stone production do not include the stone used in making cement or lime, but are as complete as possible for all other established stone quarries; but there is a large production of stone for foundation work, road-making, and railway construction of which no record is available.

The total value of the production of these structural products in 1911 according to the record obtained was $22,709,611, as compared with a value of $19,627,592 in 1910, an increase of $3,082,019, or 15.7 per cent. The total production in 1909 was valued at $16,533,349, as compared with which the 1910 production showed an increase of $3,094,243, or 18.7 per cent.

The Canadian consumption of products of this class is apparently increasing at an even more rapid rate than the production. The consumption based upon the above figures of production in conjunction with the record of exports and imports was in 1911 only a little less than $30,000,000, as against about $25,250,000 in 1910 and $20,350,000 in 1909, the increase in 1911 being 18 per cent. and in 1910, 24 per cent.

The large increase in production and consumption of structural materials is only a natural accompaniment of the great national development taking place in Canada. The normal growth of population supplemented by the large immigration now constantly in progress has resulted in a great wave of construction in the building up of cities, the construction of railways, highways, and public works of all kinds.

The building permits issued in a number of the principal cities and towns are but one proof of this growth.

Building permits in thirty-four cities in 1911 aggregated nearly $32,000,000 in value, as against $29,000,000 in 1910, an increase of over 28 per cent. and the year 1910 shows a similar increase over 1909 in permits issued of nearly 46 per cent.

A summary of the production of structural materials and clay products since 1907 is shown below:—

	1907 $	1908 $	1909 $	1910 $	1911 $
Cement	3,781,371	3,709,954	5,345,802	6,412,215	7,644,537
Clay Products	5,772,117	4,500,702	6,450,840	7,629,956	8,359,933
Lime	971,595	712,947	1,132,756	1,137,079	1,517,599
Sand-lime Brick	167,795	152,836	201,650	371,857	442,427
Sand & Gravel (exp'ts)	119,853	161,387	256,166	407,974	408,110
Slate	20,056	13,496	19,000	18,492	8,248
Stone	2,027,262	2,088,613	3,127,135	3,650,019	4,328,757
Total	12,863,049	11,339,955	16,533,349	19,627,592	22,709,611

The increase in the value of cement sales in 1911 over 1910 was 19 per cent.; clay products show an increased production of 9.6 per cent.; stone an increase of 18.6 per cent.; lime an increase of nearly 29 per cent.; sand-lime brick an increase of 15.6 per cent. The production of slate is at no time large, but shows a falling off in 1911.

The export of products of this class is comparatively small being valued at only $484,047 in 1911, of which over 90 per cent. was made up of sand and gravel. The imports, on the other hand, aggregated $7,710,552 in value, and included Portland cement, $834,876; clay products, $5,156,544; lime, $161,985; sand and gravel, $246,613; slate, $169,685; and stone, $1,140,846.

CANADIAN CAR AND FOUNDRY REPORT

Gross sales amounting to $16,500,000 are shown in the Canadian Car and Foundry Company's third annual report, and the profits for the year available for dividend purposes after providing for the first instalment of the bond sinking fund, as shown by the profit and loss account, were $1,040,000.

At the close of the fiscal year, the unfilled orders amounted in value to over $15,000,000, and at the date of the report the value of unfilled orders is $16,000,000.

An analysis of this year's statement shows that the total capital assets have grown from $11,607,734.91 to $13,384,212.65. The current assets have increased from $5,217,699.36 to $7,334,492.82. The capital liabilities amount to $15,088,306.67 as against $13,875,000 in the previous report. Current liabilities are increased $1,784,710.90 to $3,561,418.79. An increase of $383,932 is given in the balance carried forward.

A further increase in working capital is shown will be a need of the company, but until the Fort William plant is completed the directors prefer temporary banking accommodation to supply the requirements.

The comparative figures for 1912 and 1911 of the company's assets and liabilities follow:

Assets.

	1912.	1911.
Property account	$10,652,747.95	$10,147,297.41
Investment account	2,621,299.39	1,460,437.50
Cash in hands of trustees for bond sinking fund	275.31	....
Current assets	7,334,492.82	5,217,699.36
Deferred charges to operations	188,396.25	199,918.01

Liabilities.

Capital stock	$10,075,000.00	$ 9,975,000.00
Bonds	3,933,306.67	3,500,000.00
Platt & Letchworth Co.	780,000.00	....
Purchase money notes	400,000.00	400,000.00
Canadian Steel Foundries Bonds	3,650,000.00	3,650,000.00
Current liabilities	3,561,418.79	1,784,710.90
Reserve funds	707,219.47	309,307.14
Surplus	1,440,266.00	1,056,334.00

When the Fort William works are finished the company will own eight complete plants, in addition to the Rhodes-Curry building and contracting business, extending from Sydney, Cape Breton, N.S., to Fort William, Ontario, and will probably be the most self-contained car building company in the world, manufacturing, as it does, nearly everything that enters into the construction of railway cars.

The number of employees on the pay rolls and its subsidiary companies at the present time is about 7,500, and this number will be materially increased when present enlargements are completed and the Fort William Works are in operation. The pay-rolls aggregate about $500,000 per month.

◆

The Canadian Porcelain Company, Limited, has been incorporated with a capital stock of $300,000 to manufacture vitrified white porcelain for electrical and other purposes. They have purchased a 20-acre site in Hamilton, Ontario, and will erect a plant, the first unit to cost $150,000. The buildings will be of steel and brick and will be ready for operations next spring. Messrs. John Alden and Chas. Palmer, of Rochester, N.Y., and Mr. Fred D. Palmer, of Galt, Ont., are the principal directors.

COAL OF THE UNITED STATES.

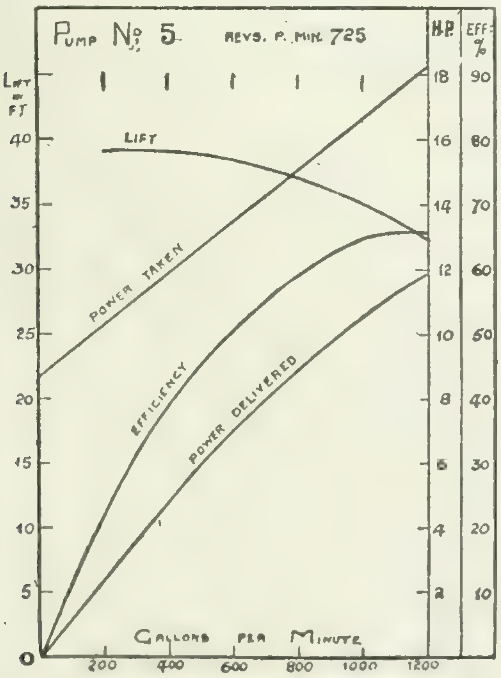
The known coal fields of the United States embrace a total area, according to the U.S. Geological Survey, of 310,296 sq. mi., to which may be added something over 160,000 sq. mi., of which little is known, but which may contain workable coals, and about 32,000 sq. mi. where the coal lies under heavy cover and is not considered available under present conditions. The supply of coal before mining began is estimated to have been 3,076,204,000,000 short tons, of which 1,922,979,000,000 tons were considered to be easily accessible and 1,153,225,000,000 short tons to be either so deep or the beds so thin that they are accessible only with difficulty. Classified according to the character of the coal, the original supply consisted of 21,000,000,000 short tons of anthracite, 1,661,457,000,000 tons of bituminous coal, 650,157,000,000 tons of sub-bituminous coal, and 743,590,000,000 tons of lignite.

The total production of coal to the close of 1911 has amounted to 2,270,798,737 short tons of anthracite and 6,468,773,690 tons of bituminous coal, or an aggregate of 8,739,572,427 tons. This total production to the close of 1911 represents including the waste of coal in mining, an exhaustion of the beds equal to 14,181,980,000 short tons, or somewhat less than 0.5% of the original supply. In other words, the quantity of coal still remaining to be mined amounts to 3,062,022,020,000 short tons, or a little more than 99.5% of the original supply. The annual rate of exhaustion at the present time as represented by the production in 1910 and 1911 is 0.025% of the supply. The quantity of coal still in the ground at the close of 1910 was 6,000 times the production of that year, or, estimating a half ton of coal lost for every ton recovered, the supply is equivalent to 4,000 times the present annual rate of exhaustion.

◆

THE STEREOPHAGUS PUMP IN OPERATION.

An eight-inch Stereophagus pump, manufactured by Messrs. Hathorn, Davey & Co., Limited, of Sun Foundry, Leeds, has been installed at The Knostrop Sewage Purification Works, of Leeds, England, with the object of testing its action under conditions exactly parallel with those prevailing with the centrifugal pumps of ordinary type now in use.



The Stereophagus pump is placed in such a position that its suction pipe dips into the stream of crude sewage issuing from the main sewer before the sewage is subjected to any screening or treatment whatever. A quantity of sewage, amounting to 500 gallons per minute, is lifted by the Stereophagus pump and deposited into a tank where it can be examined and measured.

The remaining sewage is passed on to the main centrifugal pumps, which are of large size, but before arriving at these pumps the sewage is carefully screened, so as to remove from it all substances likely to impede the action of these pumps. In spite of this, however, they require opening out for cleaning almost daily, while the Stereophagus pump, on the other hand, has not once needed cleaning, although the sewage pumped by it is unscreened.

The Stereophagus pump, which is driven by an electric motor, gave, when installed, an efficiency of over 60 per cent., as is shown by fig. 1, and that this has been maintained is proved by the fact that the quantity of sewage delivered is undiminished. The speed of the pump, and consequently the power, have, therefore, remained constant, showing an unimpaired efficiency in the pump, although during the trial a considerable amount of road grit has passed through it.

The Stereophagus Pump and Engineering Co., Ltd., 39 Victoria St., Westminster, S.W., have acquired from the Hon. R. C. Parsons the rights for the sale in Great Britain and abroad of the Stereophagus pump which was patented by him. They therefore control the Canadian rights.

◆

CANADA SOUTHERN RAILWAY BOND ISSUE

The holders of the first and second mortgage bonds of the Canada Southern Railway Company are being given the opportunity to reinvest the proceeds resulting from the payment of their maturing bonds in the company's new issue of $22,500,000 consolidated guaranteed fifty-year 5% gold bonds, Series A, dated October 1, 1912, and maturing October 1, 1962, at 105¾ and accrued interest, for each $1,000 bond of the new issue. At this price the new bond, if held to maturity, yields approximately 4.70% per annum. Messrs. J. P. Morgan & Company are authorized to handle the matter.

The consolidated guaranteed fifty-year 5% bonds upon the payment early in 1913 of a total of $20,000,000 first and second mortgage bonds now outstanding will become a direct first mortgage lien upon all of the property of the Canada Southern, except for the first mortgage of $130,000 upon the Leamington Branch, about fourteen miles in length.

Subject only to this divisional issue, the consolidated mortgage bonds after March 1, 1913, will be a first mortgage upon the 380 miles of railway lines extending with branches from the Niagara to the Detroit River. Two hundred and twenty-six miles are standard double-track trunk line railway of exceptional strategic importance, being the integral indispensable part of the Michigan Central Railroad Company route, connecting the manufacturing and distributing centres of Buffalo and Detroit, and forming with the Detroit Tunnel Company and the Michigan Central Railroad Company a part of the shortest line of the New York Central system from New York to Chicago.

The property of the Canada Southern Railway Company includes the entire main line between Suspension Bridge, Ontario, and Windsor, Ontario, opposite Detroit, with branches running to Courtright, Leamington, Amherstburg, Old Fort Erie and Niagara-on-the-Lake. Its road is of modern construction, with low gradients, easy curve, and is equipped with electric automatic block signals, etc. The lines of the Canada Southern were leased to the Michigan Central Railroad Company for a period of 999 years from January, 1904.

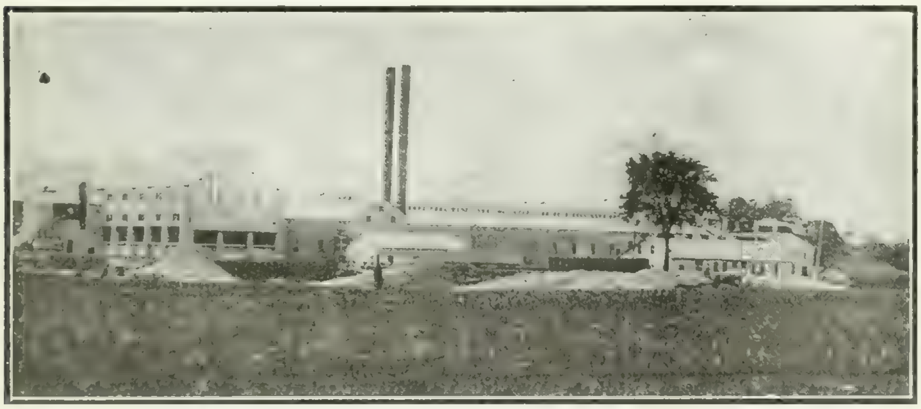
THE PLANT OF THE ST. MARY'S PORTLAND CEMENT COMPANY.

The plant of the St. Mary's Portland Cement Company is located at St. Mary's, Ontario. Its daily capacity is 1,500 barrels, and storage capacity has been provided for 75,000 barrels.

The illustration shows the buildings, but the photograph was taken before they were completed.

The quarry for limestone and the clay beds are contiguous to the mill. The plant is operated by hydro-electric power, 550-volt, 25 cycle, three-phase current being used. The company have their own substation, and find the power very satisfactory.

At the raw end a No. 8 Kennedy crusher is set over a No. 5 Jumbo Williams mill. The limestone is crushed by this to 1½ inches down. The clay is washed as it goes to the mill. The machinery includes two large size kominuters with Trix separators; two large size Smidth tube mills, and five concrete tanks. The kilns are two in number, and are 8 ft. by 160 ft. The coal is brought in on elevated tracks, is dried in a Cummer dryer, and is ground in a 42-inch Fuller Lehigh mill. Two coolers, 6 ft. by 70 ft., are provided, with a fan attachment which is used for blowing the cold air in at the lower end and using the hot air from the upper end of the cooler both for the kilns and drying the coal.



View Showing Plant of the St. Mary's Portland Cement Company During Construction.

In the finished product end, there are three Dreadnought Fuller Lehigh mills for finishing the cement.

The mill is provided with two electric cranes, one in the raw end and the other for handling the clinker. For shipment by rail, the company has both Grand Trunk and Canadian Pacific Railway connections.

The president of the St. Mary's Portland Cement Company, Limited, is Mr. Geo. H. Gooderham, and the secretary-treasurer is Mr. Mark H. Irish, both of Toronto. Mr. John G. Lind, the manager of the plant, is located at St. Mary's.

ROLLING STOCK FOR THE C.P.R.

The Canadian Pacific Railway will spend $18,000,000 in new rolling stock ordered this year. This money will secure them 467 locomotives and 28,671 cars of various descriptions. When this large order is completed the company will have in commission [illegible] locomotives and 98,804 cars. The new locomotives ordered cost nine millions, the balance of forty-eight millions being expended for cars of various kinds. This equipment will be operated over a trackage of more than 12,500 miles.

PANAMA CANAL TOLLS

Now that President Taft has proclaimed the basis of the Panama Canal toll rates to be paid by foreign shipping and ships under the American flag trading with foreign ports, steamship men in the New York shipping offices are busy figuring out estimates of what total sum an average ship may have to pay.

Owing to the many technical considerations involved it has been impossible for shipowners to make their calculations with any degree of assurance.

The provisions of the proclamation as regards merchant vessels are:

On merchant vessels carrying passengers or cargo, $1.20 per net vessel ton—each 100 cubic feet of actual earning capacity.

On vessels in ballast without passengers or cargo, 40 per cent. less than the rate of tolls for vessels with passengers or cargo.

This still leaves many important points still in doubt, and the proclamation must be taken as merely the preliminary announcement, since the rules for the measurement of vessels have still to be drawn up by the Secretary of War. Until it is known definitely whether the Panama rules of measurement will follow the British, American or Suez Canal systems of measurement for calculating the net vessel tonnage, only rough estimates can be made.

The basic rate is made to correspond closely to the Suez Canal toll, the $1.20 being practically the equivalent of the 6.75 francs, the rate which is to become effective on the first of the new year, showing a reduction of 50 cents from the present toll. It is probable that the American system of measurement will be followed, and as the American measurements come nearer to the Suez rules than to the British some clue may be obtained from ships which have the American measurement as trading with this port and have actually paid Suez Canal dues.

A steamship company's agent, in speaking of the subject, said that he was engaged on making mileage and tonnage calculations so that he could form some judgment on what it would cost his boats through the Panama Canal in order to compare the relative expenses of the alternative routes, namely, through the Straits of Magellan or by the Panama Canal. He said: "No positive or definite working criterion can yet be made. Only a rough approximation is possible, but every line knows what the net register means sufficiently to be able to take it as a guide. The American government assesses its tonnage dues on a given measurement capacity known as the American net register, and this, as I understand it, will be the measurement used in the rules to be issued by the government.

"The British net register is less than the American owing to a different basis of calculation. The British measurement does not include every available space that might be used for cargo such as extended bridge compartments, etc., but exempts those spaces when they are not used for cargo. The American measurement charges for those spaces whether used or not. It is an important technical point that should a vessel at any time go through the Suez Canal with merchandise of any kind, or lumber, coal, or stores of any description, the whole of that space is added to the net tonnage and can never more be exempted from measurement.

"The consumption of coal and the use of temporary or permanent bunker space are important items in the calculation, and shipowners using the canal for their boats will probably have to allow for permanent bunkers, as they will wish to make use of every foot of space for the cargo the ship can carry."

Another New York shipowning firm gave as a specific instance the case of a steamer having a measurement capacity of 392,958 cubic feet. Allowing 100 cubic feet as the arbitrary unit for a register ton the amount of the toll to be paid, at the rate of $1.20 a ton, would be $4,716.

Professor Emory Johnson, in his evidence, January 30, 1912, before the House Committee on Interstate and Foreign Commerce, printed in Volume II. of the Hearings, gave this rule for determining the net register tonnage of a vessel:

"There is deducted from the entire capacity of the hull the space occupied by the crew, master's cabin, steering and anchor gear below deck, boatswain's stores, chart house, and spaces occupied by propelling power (engines, boilers, shaft, tunnel, fixed coal bunkers). These deductions having been made, the net registered tonnage is ascertained by dividing the number of cubic feet in the remaining space by 100. In an up-to-date freight steamer, as measured by British, American or German rules, the net register is somewhat less than two-thirds the gross register. In the case of a high speed passenger vessel, so much of the ship is taken up with propelling machinery, fixed coal bunkers, crew space, etc., that the net register tonnage may be less than half, sometimes not more than one-third of the gross register."

To this evidence of Professor Johnson, it may be added, were appended exhibits showing tables of distances via the Panama Canal and alternative routes, number of days saved from various ports, Suez Canal data, comparative data of a ship, the Santa Rosalia, built in 1911, showing net tonnage on all three systems, viz.: British, 3,488; American, 4,392; Suez, 4,452; average price of coal at Panama and detailed statements on the relation of tolls to the volume of Panama Canal traffic.

RAILWAY RECEIPTS AND EXPENSES FOR SEPTEMBER.

The business of the railways for September while showing a considerable improvement over that of September, 1911, does not maintain the rate of increase set by the record-breaking month of August. The total net operating revenue of 90 per cent. of the steam railways increased $5,896,840 for September, while the increase for August was $13,865,622. This increase in net operating revenue was at the rate of $21 per mile of line for the month or at the rate of 70 cents per mile of line per day.

The total operating revenues per mile of line for the month increased 6.5 per cent., the operating expenses 7.3 per cent. and the net operating revenue 5.1 per cent.

The foregoing statistics are from the summary made by the Bureau of Railway Economics from the reports of the railways to the Interstate Commerce Commission. A special committee of the railways having headquarters in Chicago reports that bills now pending in the Federal Congress providing for an increase in the number of employees of the railways and for the rapid substitution of steel for wooden equipment will, if enacted, place the railways under an additional expense of approximately $12,000,000 per annum for the former, and a total expense of $632,746,000 for the latter purpose. Without compulsion, the railways in the course of three years have increased their steel equipment 750 per cent. and their steel underframe equipment 256 per cent.

UNIT COSTS OF FILTERING WATER IN FOUR SLOW SAND PLANTS AT PHILADELPHIA.

The data here given with reference to the unit costs of filtering water in four slow sand plants at Philadelphia are abstracted from the annual report of the Bureau of Water for 1911. The Queen Lane plant was not put in service until the first of December, so no results are here given for that plant. The costs and other operation data follow for the four plants in service in 1911:

Upper Roxborough Filters.—This plant comprises a storage reservoir giving a sedimentation period of 9.71 days, eight covered filter beds, and a covered clear water basin. The average rate of filtration throughout the year was 238,000,000 gals. per acre per day. The average cost of filtration was $2.98 per 1,000,000 gals., which included 65 cts. per 1,000,000 gals. for the laboratory cost. The average cost given includes all items connected with the operation of the station, but does not include the cost of pumping water from the storage reservoir to the filters. The average number of cleanings for the year was five for each filter. The average amount filtered between cleanings was 159,320,000 gals. per acre. The filters were washed for the entire year by the Brooklyn method. The cost of labor and wash water was 57 cts. per 1,000,000 gals. of water filtered, and 1,870 gals. of wash water were required per 1,000,000 gals. filtered. The results of the preliminary sedimentation in the storage reservoir are very good, the turbidity being reduced from 45 to 17 by the sedimentation. The filter removed 99.9 per cent. of the bacteria in the raw water drawn from the Schuylkill River.

Lower Roxborough Filters.—This plant consists of a storage reservoir which gives a sedimentation period of 1.29 days, five covered filter beds, eleven preliminary filter tanks, and a covered clear water basin. The average rate of filtration was 3,800,000 gals. per acre per day. The filters were operated at a rate of 508,000,000 gals. per acre per 24 hours. The cost of operation, including the preliminary filters, but not including the cost of the wash water, was $5.55 per 1,000,000 gals. filtered. This figure includes 85.4 cts. for laboratory expense. The preliminary filters were operated at an average cost of $2 per 1,000,000 gals. of water filtered by the sand filters. The sand filters were washed for the entire year by the Brooklyn method, the number of washings averaging 12.8 per filter. The average time between scrapings was 26.2 days, and the average amount filtered between cleanings was 107,550,000 gals. per acre. The average reduction of the bacteria in the raw water was 99.73 per cent. The corresponding figure for reduction of turbidity was 99.82 per cent. These figures refer to the complete treatment.

Belmont Filters.—This station is composed of a sedimentation basin giving 1.69 days' sedimentation, preliminary filters consisting of 9 filter tanks having a capacity of 40,000 gals. per 24 hours, 18 covered sand filters, and a covered clear water basin. The filters were operated at an average rate of 293,000,000 gals. per acre per 24 hours. The preliminary filters were started on October 23, 1907. They were operated at a rate of 75,000,000 gals. per acre per 24 hours this year, and have materially increased the length of runs or time between scrapings of the slow sand filters without any decrease in efficiency.

The cost of operation was $2.90 per 1,000,000 gals. filtered, which included a charge for operation of the preliminary filters and for laboratory expenses, the cost of preliminary filtration being 52 cts. per 1,000,000 gals. and the laboratory charge 33 cts. per 1,000,000 gals. The reduction in turbidity and bacteria by the action of the preliminary filters was 44.4 per cent. and 48.0 per cent., respectively.

There were 151 runs or cleanings during the year; 142 of these runs were on filters cleaned by the Brooklyn method and nine by the other methods. The average length of runs was 40.18 days, the amount filtered between runs being 94,146,000 gals., or 125,194,000 gals. per acre. While the length of runs and quantity filtered with the Brooklyn method was not so large as with the usual method, it proved economical on account of the short time it was necessary to have the bed out of service, the low labor cost of cleaning and the saving in not having to replace the sand.

Seventeen filters were operated for the entire year by the Brooklyn method. The items of cost, etc., in the process of cleaning were as follows.

Number of runs	142.
Average length of runs, days	40.4
Average m. g. filtered per run	94.53
Average m. g. filtered per acre per run	125.71
Average cost of water to wash per m. g. filtered	0.05
Average cost of labor to wash and spade per m. g. filtered	0.55
Total cost of washing and spading sand in place (water and labor) per m. g. filtered	0.60
Average gallons water used to wash sand in place per m. g. filtered	4,109

One filter yas operated during the year by the "Nichols Separators" method.

Number of runs	9.
Average length of runs, days	37.38
Average m. g. filtered per run	88.02
Average m. g. filtered per acre per run	117.05
Average cost of labor, scraping, raking and spading per m. g.	0.262
Average cost of labor washing per m. g. filtered	0.266
Average cost of water per m. g. filtered	0.02
Average cost per m. g. labor, spading, scraping, washing, water, etc.	0.55
Average gallons of water used to wash per m. g. filtered	1.336
Depth of sand scraped per run, inches	1.42
Cu. yds. sand scraped per m. g. filtered	1.590
Daily average turbidity of applied water	14.0
Daily average bacteria in applied water	21.630

Comparing the effluent from the Belmont filters with the applied water, the reductions were as follows:

	Per cent.
Average reduction, turbidity	99.34
Average reduction, bacteria	99.19

Comparing the efficient from the plain sand filters and the water from the Schuylkill River, the reductions were as follows:

	Per cent.
Average reduction, turbidity	99.74
Average reduction, bacteria	99.66

A Blaisdell Filter Washing Machine installed in 1909 for cleaning the preliminary filters has been in operation for the entire year, and has been of great benefit to the filters.

Torresdale Filters.—The Torresdale Filter Station consists of 65 0.75 acre covered beds, a covered clear water basin, preliminary filter plant consisting of 120 concrete tanks, approximately 60 x 20 ft. each, containing 1,140 sq. ft. of filtering surface, with a capacity of 240,000,000 gals. of water per 24 hours; a low lift pumping station, containing eight 40,000,000 gal. centrifugal pumps; three 150 kw. generators and four sand washing pumps, with full complement of boilers, economizers, mechanical stokers, etc.

The amount of water filtered during the year was equivalent to an average rate of 4,270,000 gals. per acre per day. The entire cost of operation, not including the expenses of the low lift pumping station, or the cost of the wash water, which are included in the expenses of the pumping station, and which amounted to $2.17 per 1,000,000 gals. of water filtered, was $1.66 per 1,000,000 gals. of water filtered, making the total expense of pumping the water from the river and filtering it, $3.83 per 1,000,000 gals. filtered, a reduction of 16 cts. over 1910. Of this amount 28 cts. was for operating the preliminary filters, and 16.8 cts. the cost of the laboratory. The filters are operated at rates approximating 6,000,000 gals. per day per acre.

The number of runs or cleanings was less than ten per filter per year, and the average length between cleanings was 35.33 days.

The standard method of cleaning adopted for 1911 was washing the sand in the filters by ejectors and Nichols Separators, the cost of which was as follows:

Number of cleanings by Nichols method	613.
Average lengths of runs, days	35.31
Average m. g. filtered per run	121.21
Average m. g. filtered per acre per run	161.61
Cost of water to wash per m. g.	0.01
Cost to rake, scrape and wash per m. g., labor	0.62
Total cost to clean	0.63
Average gallons water used to wash per m. g.	1,924.
Cubic yards scraped per m. g. filtered	1.62
Average turbidity of applied water	5.
Average bacteria in applied water	2,610.

The resanding was done during the year by Bureau labor, using Nichols Separators. There were replaced 11,017 cu. yds. in filters, at a cost of 30.6 cts. per cu. yd.

Comparing the effluent from the Torresdale final filters with the water taken from the Delaware River, the reductions were as follows:

	Per cent.
Average reduction, turbidity	99.58
Average reduction, bacteria	99.67

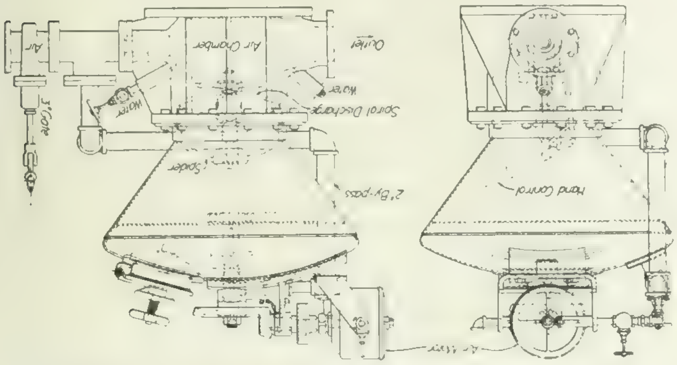
The Torresdale preliminary filters were placed in service on January 21, 1909, and since this date all water filtered by the sand filters has passed through these filters. They normally filter at the rate of 80,000,000 gals. per acre per day, but have given satisfactory results from rates of 100,000,000 gals. per acre per day. The daily average reductions in turbidity and bacteria for the year were 66.98 and 65.45 per cent. respectively. The average turbidity of the applied water to the pre-filters was 16 and the maximum 97. The per cent. of wash water used for the year averaged 0.57 per cent. of the amount filtered. The number of cleanings for the pre-filters was an average of 190 cleanings to each filter, or about 1.9 days between cleanings for the year.

GRAND TRUNK AND NEW HAVEN RAILWAYS.

In connection with the proposed traffic agreement between the Grand Trunk and the New York, New Haven & Hartford, it is stated that the final settlement of the points at issue is remote. The agreement is still in the hands of Mr. E. J. Chamberlin, president of the Grand Trunk, and his officials, and any changes which they may consider necessary will have to be submitted to the directors of the New Haven and approved by them. When all interested parties in Montreal and New York are in accord, the agreement must then be sent to London for ratification by the Grand Trunk board of directors. It is felt that all difficulties will be overcome in time since some kind of arrangement between the two roads is desirable for both.

IMPROVED DEVICE FOR DELIVERING CONCRETE.

The management of the firm of W. Van Whitall, New York, are the perfectors of a new system for concrete distribution by means of compressed air furnished by a blower as illustrated in the accompanying illustration. The blower consists of a steel drum or receiving hopper bolted to a cast steel discharging pan. A shaft, passing through the drum, is connected by suitable gears and bevel to an Ingersoll-Rand four-piston air motor. The air is admitted through a hand-controlled valve to a flanged pipe leading directly to the air chamber. A 2-in. by-pass leading to the air motor is placed in this pipe in front of the air chamber. In this way the operation of the machine starts simultaneously with the admission of air to the line. Globe valves are placed on this by-pass line to permit of proper control of the pressure. Water is admitted through two connections at the front and back of the air chamber. The concreting materials are spread in alternate layers of stone, cement and sand and shoveled directly into the drum. As they pass from the latter into the air chamber the water spray is encountered and the combination of air and water results in a thorough mixing.



Blower for Transporting Concrete by Compressed Air.

◆

CROSS-WISE BENDING TESTS OF RAIL FLANGES.

The failure of the rail which caused the wreck on the Wabash Railroad near West Lebanon, Indiana (U.S.A.), on March 7th, seems to have been caused by the seaminess of the metal in the base of the rail. Mr. James E. Howard, engineer-physicist of the United States Bureau of Standards, in a report of his investigation issued by the Interstate Commerce Commission, writes: "The steel was seamy, and the initial line of rupture occurred along the line of a seamy streak. Herein is exhibited a structural defect which is prevalent, to a marked degree, in many rails. It is a defect, the presence of which is well recognized and admitted. Notwithstanding these circumstances, rails are accepted under specifications and tests in which this, the most comman cause of breakage, is not guarded against." Mr. Howard mentions the fact that this seaminess of the metal can be revealed by cross-wise bending of the flanges. About 27 per cent. of the head of the rail in question was worn down, and careful track inspection should have revealed this, but the seamy streak in the base, which, no doubt, caused its rupture, could not have been detected by inspection. As the author states, this was a defect of manufacture which current specifications and tests are not adequate to discover, though not less than 80 per cent. of broken rails reported, covering certain periods, are of the type here encountered.

COMPRESSED-AIR SEWAGE DISPOSAL.

Some interesting details concerning the compressed-air plant for removing the sewage of the small town of Allenstein, in Eastern Prussia, are given by R. Luckhardt, the director of the municipal gas and waterworks of the town, on the strength of thirteen years' experience. The town of Allenstein, though still a small country place of not more than 35,000 inhabitants, has rapidly grown in the last four decades; in 1870 the population barely amounted to 6,000 people. The River Alle, on which the town is situated, runs through a hilly country, and there are level differences of more than 100 ft. in the main streets. The Shone system of canalization having been shown at the Berlin Trade Exhibition of 1896, its municipality sent a committee over to England to study this system, and the contract was entrusted to the Gesellschaft Hydow, of Berlin. The plant was completed in 1899. There were difficulties at first, but on the whole the system has answered, and, as little has been published on the subject, Luckhardt's report in the "Zeitschrift des Vereines Deutscher Ingenieure" of November 2nd, 1912, will be found of interest. The working expenses amount to 0.67 mark per head per year, and the annual cost of the whole plant, including interest and depreciation and settling-tanks is estimated at 2.66 marks (58 cents) per head.

◆

LARGE GAS ENGINE ORDERS.

The Mesta Machine Company, Pittsburg, Pa., have received two orders for gas engines in the past month which are worthy of particular mention on account of some features not usually encountered in this class of work.

The first order comprises three single tandem, horizontal double-acting, four-cycle engines, having cylinders 28-inch diameter by 36-inch stroke, to operate at a speed of 150 r.p.m., each arranged to drive direct connected a 500-kw., 60-cycle, 3-phase, 600-volt, alternating current generator. These engines are to be installed by the Canadian Car and Foundry Company, at their new Fort William, Ontario Province, plant, and will be the largest producer gas engine plant in Canada.

The main gas plant consists of four double bituminous coal generator sets furnished by the R. D. Wood & Company,, Philadelphia, Pa. The gas plant was originally intended for fuel gas purposes, but as it is necessary to intermittently change from water gas operation to producer gas it was decided to utilize the waste, or producer gas, for power purpose. This gas will contain more than 10 per cent. hydrogen by volume, and is particularly suitable for use in gas engines.

The fuel gas which will be used for furnace work will have a heat value of 300 B.t.u. per cubic foot, and will contain 50 per cent. H and 30 per cent. CO. The operation of the producers will be such that it will be practically impossible to mix the gases, that is to say, the regulation of the gas will be automatic, eliminating any liability of water gas being carried to the engines. In the use of double generator sets the gas is drawn off the top of one generator and down through the incandescent mass of the other, the tar being consumed and converted into gas, thereby increasing the efficiency of the plant. Soot, of course, will be the resulting deposit. This soot will be disposed of through Thiesen washers.

The other order comprises three engines of exactly the same size for the Alpha Portland Cement Company, Easton, Pa. The engine will be located at Cementon, N.Y., near Catskill, and will operate in parallel with four producer gas engines now in service. Gas is generated through R. D. Wood & Company's superimposed pressure type producers, using bituminous coal as fuel.

COAST TO COAST.

Montreal, Que.—The Montreal harbor revenue for the past season was $461,396.43, an increase of $30,000 over those of 1911.

Calgary, Alta.—Payment of a small fee as rental to the city for the use of the street while building operations are being carried on is being considered by the commissioners.

Brantford, Ont.—Slush and ice clogged the intake of the power house supplying this municipality with light, and as a consequence the town was in darkness during the nights of December 11th and 12th.

Sydney, C.B., N.S.—The output for the Dominion Iron and Steel Company for the month of November was as follows: Coke, 46,660; pig iron, 28,670; steel ingots, 28,010; blooms, 27,060; rails, 15,385; rods, 7,250. Total shipments, 26,520 tons.

Toronto, Ont.—The steady advance in the mineral production of Ontario is strikingly shown by the annual report of the Bureau of Mines for 1911. The total production had a value of $41,976,797, an increase of 6.7 per cent. compared with the previous year. From 1906 to 1911, Ontario's output of minerals increased in value by 87 per cent.

Welland County.—Engineer C. Gardner, who has had charge of the work on the good roads throughout the county, submitted his report to the county council at their last meeting. Five and a half miles of good roads have been built in the county during the past year at a cost of $2,700 per mile. In Bertie township thirty-five days' work was done, in Thorold one hundred and forty-seven days, and in Stamford one hundred and forty-five days.

Dauphin, Man.—The members of the Board of Trade met in session last week, President R. Lilly presiding. The various items of work accomplished, and in hand, were explained, showing much time and labor having been spent in obtaining all particulars for the erection and operation of a hydro-electric power plant at Meadow Portage, where it is estimated 25,000 h.p. can be obtained. Government engineers have interviewed the board and reported favorably, and the city council have now the project in hand with a view of having it installed at the earliest moment. The installation of such a plant will give cheap light and power for manufacturing purposes.

Dauphin, Man.—At the last meeting of the city council a report was brought up by the Fire, Light and Power Committee. It was explained that owing to the rapid growth of the city, the power plant was being worked to its capacity, and it was impossible to undertake any more installations. Various suggestions were made for temporarily relieving the pressure. It was the unanimous opinion of the council that a new plant should be built with three times the capacity of the present outfit, and so arrange that a heating plant be connected for the purpose of supplying heat to the business and residential blocks from the exhaust steam The contractors of the sewerage and water plant were granted an extension of time to complete the few outlaying points that are necessary to finish their contract. Building permits for the month ending November 31st total $135,425, as against $58,255 for the same time last year.

Victoria, B.C.—To raise the status of the logging engineer and to provide for the training of more men for the industry is the object of Mr. G. M. Cornwall, a well-known lumberman, of Portland, Ore., and proprietor of the "Timberman." With such a purpose, Mr. Cornwall called on Mr. F. L. Carter-Cotton, chancellor of the new British Columbia University, recently, to urge upon him the necessity of establishing a course in logging engineering in connection with the university. Mr. Cornwall pointed out that the Pacific Logging Congress was doing its utmost to raise the occupation of logging engineer to the status of a profession, and that the inclusion of a course designed to turn out qualified men from the university would be a great advance.

Toronto, Ont.—On a report by the engineer, Mr. E. L. Cousins, the consulting engineer, Mr. J. G. Sing, and the secretary, Mr. Alex. C. Lewis, regarding the separation of grades along the waterfront, the Toronto Harbor Commissioners unanimously decided that the property of the commissioners would be irretrievably damaged by any of the proposed solutions of the problem other than the viaduct order of the Dominion Board of Railway Commissioners, or by any deviation from the viaduct plans as approved by the board. The chairman, Mr. L. H. Clarke, was given authority to take whatever action he thought necessary to safeguard the interests of the commissioners.

Stratford, Ont.—At a special session the city council, by a unanimous vote, gave the street railway by-law its second reading, and it will go to the ratepayers on January 6th. The by-law grants the Stratford Railway Company a twenty-five-year franchise, and leaves the builders free to obtain their power elsewhere than from the Hydro-Electric Commission if cheaper. It provides for construction to begin by June 1st, 1913, if the by-law is confirmed by the Legislature. The power clause was explained by the city solicitor as requiring the consent of both council and ratepayers before the company can sell of lease electric power in the city. The Canadian Northern Railway, through Sir Wm. Mackenzie, has pledged itself to build the railway.

Toronto, Ont.—The Toronto Railway Company will be asked by the city to place in service 150 new motor cars of approved modern type, as recommended by the transportation experts, Mr. Bion J. Arnold, of Chicago, and Mr. J W. Moyes, of Toronto, in their report, as well as to construct the lines in the older portion of the city suggested by the experts. They state that 150 modern motor cars are required at present to give a reasonable service on the lines. They also recommend that the company be asked to undertake to add new motors as fast as it builds new lines. The experts recommended the extension of Victoria Street north to Bloor Street "at any reasonable cost." They say: "This would prevent the crowding of traffic on either Yonge or Teraulay Street, these three streets offering sufficient transportation facilities for many years to come." The company will be asked to construct and put into operation at once a number of other lines.

GOVERNMENT SHIP RETURNS FROM ARCTICS.

The Canadian Government's ship "Arctic," which left Quebec on June 29th last, under the command of Commander Jackson, returned to Quebec on Saturday, November 16. All on board were well, and there were no complaints made by the members of the crew. The commander said he had been employed most of the time taking surveys in Hudson's Bay Straits, and as a result of the work there would be considerable changes in magnetic variations. He also took soundings and observations for ice conditions. He refused to express an opinion as to the practicability of the Straits as a route for grain.

◆

Fort William's new industrial plants are making much progress toward completion. Additional elevator capacity and harbor facilities are being planned. When these various developments are completed the citizens will be claiming largest manufacturing city of the west.

PERSONAL.

JOHN McGILL has been appointed assistant manager by the Berg Machinery Manufacturing Company, Toronto.

A. S. GOING has been appointed engineer of construction for the Grand Trunk Railway System, with headquarters at Montreal, Que.

GORDON KRIBS, B.A.Sc., graduate of the University of Toronto, formerly assistant to the chief engineer of the Pacific Power & Light Company, Portland, Ore., is now assistant to the chief engineer of the Texas Power & Light Company, Dallas, Texas.

SUPERINTENDENT WHITE, of the Eastern Canada Power and Pulp Company's ground wood mill at Murray Bay, Quebec, has been appointed superintendent of the new one-hundred-ton ground wood mill, which will be erected by the Abitibi Pulp and Paper Mills.

T. R. DEACON, O.L.S., M.Can.Soc.C.E., has just been elected mayor of Winnipeg. Mr. Deacon is a graduate of the University of Toronto in civil engineering of the class of '91, and is president and general manager of the Manitoba Bridge and Iron Works, Limited.

G. SYLVESTER, of Calgary, Alta., has been elected one of the executive of five officers representing the various divisions of the American Association of Manufacturers of Sand Lime Products, the annual convention of which was held at the King Edward Hotel, Toronto, December 3rd and 4th.

ALFRED E. ROSEVEAR, recently appointed assistant to vice-president of the Grand Trunk, with headquarters at Montreal, Que., was born on February 20, 1863, at Montreal, and was educated at Montreal Academy. He began railway work on May 1, 1879, as a clerk in the motive power department of the Grand Trunk. The following year he was made clerk in the general superintendent's office, and from 1885 to 1890 was stenographer in the general manager's office. From 1890 to 1892 he was with the West Shore Fast Freight Line at Chicago and at Detroit, Mich., and then for six years was in the accounting department of the Reading Despatch at Detroit, becoming acting manager of the same line in September, 1898. He was appointed freight claim agent of the Grand Trunk in October, 1898, and in April, 1908, was promoted to assistant general freight agent of the same road, which position he held at the time of his recent appointment as assistant to vice-president.

RICHARD COLCLOUGH, recently appointed assistant to the general superintendent of the Intercolonial Railway and the Prince Edward Island Railway, with headquarters at Moncton, N.B., was born on February 24, 1871, at Bic, Que. After leaving the common schools he attended Rimouski College, and in 1888 graduated with the degree of B.A. from Laval University, Quebec. He began railway work on December 9, 1889, with the International Railway as a clerk in the superintendent's office at Moncton, and has been in the continuous service of that company ever since. From 1892 to November, 1901, he was private secretary to the chief superintendent, then to the general manager, and later to the general superintendent and manager. He was subsequently chief clerk in the manager's office until October, 1902, when he was appointed clerk in the general manager's office and in the office of the managing board. From June, 1911, until the following May he was chief clerk in the general superintendent's office, and in May, 1912, was appointed assistant superintendent of the Halifax & St. John division, which position he held at the time of his recent appointment as assistant to the general superintendent.

S. B. WILLIAMSON, since 1908 division engineer of the Pacific Division of Panama Canal Construction, has resigned his position to enter the service of J. G. White & Co., Limited, international engineers and contractors, of London and New York. Mr. Williamson was called to the canal service by Col. Goethals in May, 1907, as division engineer of the Pacific locks and dams. In his later position he had charge of the construction of the gigantic locks at Pedro Miguel and Miraflores, involving the placing of vast quantities of concrete, extensive dry excavating and dredging; the construction of terminal docks at the Pacific entrance, and municipal work in Panama City, and the Canal Zone south of Culebra. Previous to his work in Panama, Mr. Williamson was engaged in railroad and general construction work in various parts of the United States. He was also in the service of the United States government for some time, and in 1900 was in charge of the fortification work at Newport, R.I. In his new field of work, with J. G. White & Co., Limited, he will be associated with their London office in the capacity of principal assistant engineer, directing construction in all parts of the world excepting the United States and its possessions.

DEATH OF NOTED SCIENTIST.

The death is reported of Sir George Howard Darwin, second son of the famous Charles Robert Darwin, who won notoriety through his lectures and publications along the lines of nature and evolution. Sir George Howard Darwin was professor of astronomy and experimental philosophy at Cambridge University, he was 67 years of age.

FIRE LOSS OF THE UNITED STATES AND CANADA.

The fire loss of the United States and Canada during the month of October, as compiled by the Journal of Commerce, shows an aggregate of $13,651,650, as compared with $13,945,000 for the same month of 1911, and with $37,188,300 in October, 1910, when climatic conditions resulted in serious losses from forest fires. The fire losses for the first ten months of 1912 reach the sum of $191,181,600, as against $192,933,800 for the same time in 1911,

	1910.	1911.	1912.
January	$15,175,400	$21,922,450	$35,653,450
February	15,489,350	16,415,000	28,601,650
March	18,465,500	31,569,800	16,650,850

Total year	$234,470,600	$234,337,250	....

MEETING OF THE CANADIAN SOCIETY OF CIVIL ENGINEERS.

The monthly meeting of the society was held on Thursday, December 19th, in the society rooms, 413 Dorchester Street West, Montreal. Mr. H. H. Vaughan, assistant to the vice-president of the Canadian Pacific Railway, read a paper on "Rotary Snow Plows."

MEETING OF ENGINEERING ALUMNI, UNIVERSITY OF TORONTO.

At a dinner of the Engineering Alumni Association of the Faculty of Applied Science, University of Toronto, held on December 17th in Toronto, at which 125 were present, and over which the president, Mr. J. C. Armer, presided, there was a discussion of the research scholarships which the association is founding, and the announcement was made that next year research work would be done by Messrs. W. P. Dobson and M. R. Shaw. Mr. Dobson's work will be that of studying the electrical surges in transmission systems, due to the switching of loads on and off. The University of Toronto and the Ontario Hydro-Electric Commission are working in conjunction to give Mr. Dobson the necessary equipment and assistance. Amongst those who spoke at the dinner were Dean Galbraith, of the University of Toronto; Mr. J. E. Ritchie, president of the University Engineering Society; Mr. C. H. Mitchell, consulting engineer, and Prof. H. W. Price, of the University of Toronto.

COMING MEETINGS.

AMERICAN WOOD PRESERVERS' ASSOCIATION.—Ninth Annual Convention will be held at Chicago Jan. 21-23, 1913. Secy-Treasurer, F. J. Angier, Mount Royal Station, B. & O. R. R., Baltimore, Md.

AMERICAN INSTITUTE OF CONSULTING ENGINEERS.—Annual Meeting, January 14th, 1912, will be held at The Engineers Club, 32 West Fortieth Street, New York, N.Y. Secretary, Eugene W. Stern, 103 Park Avenue, New York.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annua Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings,

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh B. Fergusson, 911 Rogers Building, Vancouver, B.C. Headquarters: McG University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr, G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O, Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only, unless otherwise noted, at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close	Noted in issue of
1-18—Trunk Sewer Extension, Edmonton, Alta. ....(P. & S.)	12-19

◆

TENDERS PENDING.

In Addition to Those in this Issue.

TENDERS.

Calgary, Alta.—John Stocks, Deputy Minister of Public Works, Edmonton, Alta., will receive sealed tenders for "electric wiring, Court House, Calgary, Alta.", up to noon December 23rd. Specifications, forms of tender may be had at the office of the Department of Public Works, Calgary, or at the office of the Provincial Architect, Department of Public Works, Edmonton.

Calgary, Alta.—J. M. Miller, City Clerk, will receive sealed tenders up to noon December 24th for the supply of lap-welded steel pipe as required by the city commissioners. Specifications, etc., may be obtained from the above.

Edmonton, Alta.—Tenders for trunk sewer extensions, addressed to the City Commissioners, Edmonton, will be received until January 18th, 1912. Plans and specifications may be seen at the offices of the City Engineer, Edmonton; "The Canadian Engineer," Toronto, and "Engineering Record," New York. (For full particulars see advt. elsewhere in The Canadian Engineer). City Commissioners.

Kamloops, B.C.—J. J. Carment, city clerk, will receive tenders up to December 26th for 150 electric lights. Particulars may be obtained from the above.

Ottawa, Ont.—Tenders for the construction of six 300 cubic yards' capacity steel hopper scows, will be received at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa, until January 7th, 1913. Plans, specifications and form of contract can be seen and forms of tender obtained at Mr. Desrochers' office, and at the offices of T. H. Schwitzer, Esq., Mechanical Superintendent, Birks Building, Ottawa; J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto; C. E. W. Dodwell, Esq., District Engineer, Halifax, N.S.; and H. H. Donnelly, Esq., Superintendent of Dredges, St. John, N.B.

Quaco, N.B.—Sealed Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, and endorsed "Tender for wharf at Quaco, N.B.," will be received at this office until 4.00 p.m. on Monday, December 30, 1912, for the construction of a wharf at Quaco, St. John County, N.B. Plans, specification and form of contract can be seen and forms of tender obtained at this department, and at the offices of F. G. Goodspeed, Esq., district engineer, St. John, N.B.; Geoffrey Stead, Esq., district engineer, Chatham, N.B.; and on application to the postmaster at Quaco, N.B. Each tender must be accompanied with a marked check on a chartered bank for a sum equal to 10% of the tender price, payable to the Honorable the Minister of Public Works.

Regina, Sask.—Tenders for the supply and erection of a five million gallon turbine pump and compound condensing vertical engine, will be received by the City Commissioners up to noon of January 29th, 1913. Copy of specifications and conditions may be obtained from R. O. Wynne-Roberts, consulting engineer. (See advt. elsewhere in The Canadian Engineer).

St. John, P.Q.—Tenders for the construction of a steel bridge with reinforced concrete flooring, between the towns of St. John and Iberville, P.Q., will be received by J. A. Raymond, secretary-treasurer of the town of St. John, until December 23rd. Plans and specifications may be seen at the office of Baulne and Mercier, consulting engineers, 503 Power Building, Montreal.

◆

CONTRACTS AWARDED.

Brantford, Ont.—Messrs. Schultz Bros. have been awarded the contract for the erection of a vaudeville theatre for Mr. James O'Reilly. Messrs. Stewart and Whitton are the architects.

Calgary, Alta.—The following tenders have been recommended to the council for acceptance:—The Ottawa Car Company for:

12 41 ft. 6 in. car bodies, $3,420 each, $41,040.
12 46 ft. 6 in. car bodies, $3,615 each, $43,380.
6 44 ft. 6 in. trainers, $3,467 each, $20,002.
30 Set Brill, 22 G 1 truck, $925 each, $27,690.
Total: $132,912.

The Canadian Westinghouse Company for:—

24 complete quadruple motor equipments, $2,350 each; $56,400.

24 complete air brake equipments, $236.90 each, $6,864. Total, $63,264.

Cap a l'Aigle, P.Q.—The contract for an extension to the wharf of this municipality has been awarded to Nap. Trudel of St. Irenie, P.Q.

Edmonton, Alta.—The contract for the supply and erection of a sub-structure for a bridge, to be on 5th Street, has been awarded to Messrs. Lyall-Mitchell Company, of Edmonton, at a cost of $79,898.18. Five other offers were considered; they ranged in price as high as $133,000.

Grimsby, Ont.—Public building: Contractor, E. A. Bleakney, Esq., of Gananoque, Ont.

Longueuil, P.Q.—Dredging: Contractors, The W. J. Poupore Co., Ltd., of Montreal, Que.

Preston, Ont.—Contracts for work on the new factory to be erected by the Anchor Bedding Company have been awarded as follows:—Mason work, Wirsching Bros.; carpenter work, James Eagle. The architect is H. Gale Legg.

Quebec, P.Q.—The Harbor Commissioners of Quebec have ordered 3 six-wheel switching locomotives from the Montreal Locomotive Works. The dimensions of the cylinders will be 19 in. x 26 in.; the diameter of the driving wheels will be 50 in., and the total weight in working order will be 120,000 lbs.

South Vancouver, B.C.—Mr. S. D. Rogers has been awarded a contract to erect two annexes to schools in this municipality at a cost of $1,475 each.

Stratford, Ont.—The contract for the building of the new Bank of Toronto has been awarded to Mr. Wm. Bradshaw of the city.

Victoria, B.C.—The management of the Sound Construction Company have been awarded the contract for the erection of the superstructure of the building to build for the British Columbia Permanent Loan Company; it is to be a ten story structure and will cost about $200,000.

RAILWAYS—STEAM AND ELECTRIC.

Brantford, Ont.—There will be much railway work in the vicinity of this town according to the present plans. Among the lines proposed are the Brantford and Hamilton Electric Railway, The Imperial Traction Company, The Huron and Ontario and the Niagara, St. Catharines and Toronto.

Hamilton, Ont.—The management of the Hamilton Street Railway Company are negotiating with the civic council regarding certain proposed extensions to the present system.

Ottawa, Ont.—The Grand Trunk Pacific Railway officials are negotiating with the federal government for an extension of time for the completion of all western lines of this company.

New Brunswick.—The Intercolonial Railway has finished work on 8.3 miles of new line in the province of New Brunswick from Nelson to a point two miles east of Chatham to replace the old line between these two places. Work is now under way between Georges River and Sydney Mines on nine miles.

Province of Quebec.—Work is now under way on a 30-mile extension of the Quebec and Lake St. John Railway from Roberval, north. Mr. J. P. Mullarky, Montreal, is the contractor.

Vancouver, B.C.—The Canadian Northern Railway have called for public tenders for the construction of its proposed Lulu Island branch from a point at the upper end of the island to a point adjacent to the Y of the British Columbia Electric Railway on the west boundary of section twelve, block three, north, adjacent to Steveston, a distance of 10.2 miles.

Western Canada.—The double tracking programme of the Canadian Pacific Railway for the year 1913 calls for 1,100 miles of new track.

LIGHT, HEAT AND POWER

Brandon, Man.—The civic power committee are considering the erection of a power plant at a point eight miles east of the city. City Engineer Speakman is a member of the committee.

Galt, Ont.—The Town Council has passed a by-law providing for placing the control of the local hydro-electric department in the hands of a commission, to consist of two members and the mayor.

Prince Albert, Sask.—It is probable that an expenditure of about $200,000 will be made during the coming year to erect a first-class power and light station.

Sarnia, Ont.—The municipal council are making a preliminary investigation into the possibilities of installing hydro-electric current into this municipality.

GARBAGE, SEWAGE AND WATER.

Brantford, Ont.—The municipal council will ask the ratepayers to endorse a by-law allowing an issue of debentures for the sum of $15,000 to be used for the construction of works to prevent damage from floods which occur in the spring by reason of the Grand River overflowing the bank.

Montreal, P.Q.—The following firms have tendered on the installation of a water heater as required by the city engineer:—Messrs. Laurie and Lamb, H. L. Peiler and Co., H. W. Petrie, of Montreal, Ltd., and Larling Bros., Ltd., each tender is on the same price basis, namely, $2,500.

Montreal, P.Q.—The following five firms have tendered on the installation and manufacture of a 12,000,000-gallon pump; they all submitted the same price of $80,000. Messrs. Heap & Gardners, Ltd., Escher, Wyss & Co., the John McDougall Caledonia Iron Works, the Canada General Electric Company, and Drummond McCall an dCo.

Victoria, B.C.—City Engineer Rust has presenter a report to the council which shows the expenditure of the $700,000 will be requested from the ratepayers for drainage works. The report allows an expenditure of $519,330 for north-east and north-west sewer extensions, and $78,900 for surface drainage extensions.

Victoria, B.C.—Engineers of the municipal water department are preparing a report on their examination of all waters in the districts of Golden, Cranbrook, Fernie, Grand Forks, Similkameen, Kelowna, Vernon, Ashcroft and Lytton.

BUILDINGS AND INDUSTRIAL WORKS.

Province of British Columbia.—There is a likelihood that the Dominion Tar and Chemical Company may establish a plant in British Columbia for the manufacture of creosote and other by-products of coal. Mr. Harold Boulton, London, England, a director of the company, is at present investigating the prospects.

Calgary, Alta.—It is reported that Col. James Walker will erect a $500,000 theatre in this city.

Calgary, Alta.—The management of the Riverside Sash and Door Company will erect a large factory in this city.

Fredericton, N.B.—Mr. David Richards is negotiating for a site in this city suitable for the erection of a theatre.

Haileybury, Ont.—M. J. O'Brien, Cobalt, Ont., is interested in a projected paper mill which in all probability will be erected at this point in the near future. It is planned to commence with 750 employes.

Kingston, Ont.—The management of the American Creosote Wood Block Preserving Company are negotiating with the municipal council regarding the location of a branch factory in this city. The ratepayers will be asked to provide a suitable site.

London, Ont.—If the ratepayers endorse a by-law to raise $250,000 for a Federal Square the McCormick Manufacturing Company will erect a new building in the eastern part of the city.

Port Arthur, Ont.—The Board of Education have decided to erect two new schools during the summer of 1913.

Saskatoon, Sask.—It is reported that certain members of the Slav colony will invest the sum of $50,000 in a plant for the manufacture of all varieties of iron, contracting work, and sheet steel articles. Mr. C. J. Alexander is interested in this project, which is to be known as the Toil Corporation, Ltd.

Seaforth, Ont. Mr. William J. Duncan is negotiating for freedom from taxation, and if the same is obtained will convert the old Grip Hotel into a factory.

Barrett Specification Roofs

A Mile of Barrett Specification Roofs

The wonderful Bush Terminal in Brooklyn, New York, illustrated below, includes 181 buildings, comprising tremendous warehouses, enormous pier sheds for docking ocean steamers, huge factory buildings, a large modern power house and an enormous freight structure. These buildings stretch for a mile along New York harbor. Their total roof area is 3,100,000 square feet—more than seventy acres.

The entire area was covered with Barrett Specification type of roofs, for the following reasons:

1. Low first cost.
2. No maintenance expense, such as painting, etc.
3. They are not injured by steam, gases and acid fumes.
4. They are fire retardent and take the base rate of insurance.
5. The net unit cost, that is, the cost per foot per year of service, is lower than that of any other type.

Although some of the buildings are fifteen years old, the roofing contractor states that the expense for maintenance of this entire roof area has been less than $10.00. He estimates that if metal or ready roofings had been used, it would have been impossible to keep the buildings free from leaks and that the painting bill alone up to date would probably have amounted to at least $50,000.00.

We wrote to the Bush Terminal Company, asking what they thought about Barrett Specification Roofs. The Vice-President replied:

> "We use this kind of roofing because our experience has shown it to be the best and cheapest. Our analysis of first cost of application and cost of maintenance entitles us to speak with some measure of authority."

We shall be pleased to mail architects, engineers or owners of buildings copy of our Barrett Specifications with diagrams from which blue prints can be made. Address the nearest office

Special Note

We advise incorporating into plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired, however, the following is suggested.

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15, 1911, using the materials specified, and subject to the inspection requirements.

THE PATERSON MANUFACTURING CO., LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER ST. JOHN, N.B. HALIFAX, N.S.

Victoria, B.C.—It is expected that the Department of Public Works will soon be in a position to invite tenders for the erection of the new Provincial Normal School in this city.

Winnipeg, Man.—The congregation of the Central Congregational Church have $70,000 toward the erection of a new church building. Doctor J. L. Gordon is the pastor.

BRIDGES, ROADS AND PAVEMENTS.

Calgary, Alta.—The ratepayers will be asked to provide sufficient money to cover the cost of an additional unit to the paving plant.

St. John, N.B.—Word comes from this point that a number of ratepayers around Loch Lomond are considering the matter of road improvement. Mr. Fred. Watters acted as chairman at a recently-held good roads meeting.

Welland, Ont.—The actual cost of county road construction has been found to be $3,222.87 per mile as against the estimate of $2,690.

West Point Grey.—A committee has been appointed to secure the assistance of the provincial government and the municipal council in the construction of a concrete archway bridge to be erected over a ravine near this point. Those appointed to act are Messrs. W. R. Arnold, A. G. McKennie, D. Morrison, John Weeks and Dr. Tanner.

FIRES.

Cobalt, Ont.—The plants of the Jajola 20th Century mines were damaged by fire to the extent of $3,500,000. Mr. S. Sager is interested in these workings.

Hespeler, Ont.—The moulding shop of the Canada Machinery Corporation was damaged by fire to the extent of $20,000.

Stratford, Ont.—The plant of the Stratford Mill Building Company was destroyed by fire with a loss of $75,000.

Vancouver, B.C.—The works of the Hoffar Motor Boat Works were damaged by fire to the extent of $14,000.

Watson, Sask.—The store of Messrs. Schinkler Bros., builders' supplies, was destroyed by fire.

CURRENT NEWS.

Berlin, Ont.—The ratepayers will be asked to vote the expenditure of $30,000, to be used in the construction of an abattoir.

Montreal, P.Q.—The Williams Manufacturing Company, manufacturers of sewing machines and typewriters, has been re-organized and now has a capital of $1,000,000. It is the intention of the directors to expand the buildings and allow of a heavier output. Montreal men on the directorate include Messrs. C. W. Davis, B. McLennan, James Rodger, and William Yuile.

Montreal, P.Q.—Messrs. Price, Waterhouse and Company have made an investigation into the public service commission on the Montreal Harbor Commission, and report this department in a fair shape. Several recommendations are made, one of which provides that all the accounting and cost records of every department be placed in charge of a chief accountant or comptroller, who should have the entire responsibility for all accounting.

Vancouver, B.C.—The following firms tendered on the supply of 4-inch, 6-inch, 8-inch, 12-inch iron pipe and 2-inch galvanized pipe as required by the engineering department. The tenders were put in as follows: Messrs. Gerald Lomer & Co., $300,000; Messrs. Frank Darling & Co., about $220,000; Messrs. Wilkinson & Co., $280,000; Messrs. Balfour, Guthrie & Co., $288,580; Messrs. Robertson, Godson & Co., about $320,000; Evans, Coieman & Evans, Ltd., $160,750, and (alternative) $164,000.

Victoria, B.C.—Messrs. Sharpe and Thompson, architects, Vancouver, B.C., have been awarded the prize for the design and plans of the building for the proposed university of British Columbia.

It is reported that the officials of the Canadian Northern Railway are considering the erection of a line of hotels along their right-of-way from Halifax to Vancouver.

Victoria, B.C.—The Board of Education are planning to spend $150,000 on new school buildings in the near future.

Windsor, Ont.—The ratepayers voted the usual tax exemption to the Tudhope Motor Company and the Canadian Roofing Company, both of which are to locate factories here.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending December 2nd, 1912:—

A London correspondent desires to get into communication with Canadian manufacturers of wire and wire nails.

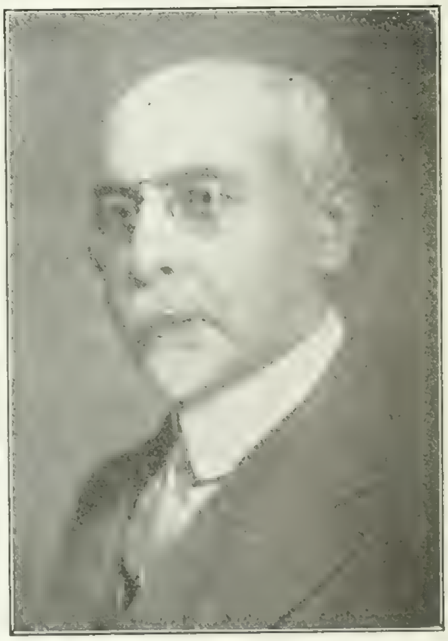
A Sheffield firm manufacturing razors, clasp knives, desk knives, and all classes of table knives, butchers' knives, cooks' knives, kitchen knives, and forks, desire to do Canadian business.

A Belgian manufacturing and export company desire to enter the Canadian market for tissues, laces and embroideries; also paper, chemicals and pharmaceutical products.

A German firm of automobile manufacturers desire to appoint high-class agents in Canada.

NEW DIRECTOR OF BANK OF TORONTO.

Mr. J. L. Englehart has been elected a director of the Bank of Toronto in place of Mr. W. H. Beatty, deceased. Mr. Englehart is best known perhaps as chairman of the Temiskaming and Northern Ontario Railway Commission. In that capacity he has not only shown an excellent grasp of railroad problems and affairs but has maintained also an unmatched enthusiasm respecting the prospects and development of Northern Ontario, backing his opinions with hard work.



J. L. Englehart.

Mr. Englehart was born at Cleveland, Ohio, in November, 1847. Since 1866 he has been the head of the firm of Messrs. J. L. Englehart and Company, engaged in the refining, producing and exportation of Canadian petroleum and its products, with works in London, Ontario, and offices in New York. He was one of the pioneers in the trade. In 1881, he removed to Petrolea, Ont., where he became second vice-president of the Imperial Oil Company. He is also vice-president of the Crown Savings and Loan Association, Petrolea, and vice-president of the London and Western Trust Company, London, Ont. He has been a governor of Toronto University.

AGENTS FOR CANADA:

LAURIE AND LAMB
211 BOARD OF TRADE BUILDINGS,
MONTREAL.

THE GUTTA PERCHA AND RUBBER MANUFACTURING CO., OF TORONTO, LIMITED, TO BE REORGANIZED.

There is to be a reorganization of The Gutta Percha & Rubber Manufacturing Company, of Toronto, Limited. whose factories are located in Toronto (Parkdale). The reorganization will take effect as of January 1st, 1913. The company has carried on an extensive business throughout Canada and by export to various parts of the world for over a quarter of a century, having been incorporated as a purely Canadian industry under the Ontario Joint Stock Companies Act in 1887.

As the business of the company grew, it became necessary to open branches in many places. At some points these branches were operated under the name of "The Gutta Percha & Rubber Mfg. Co., of Toronto, Ltd.", but in the prairie provinces the business has been conducted at Winnipeg and Calgary through a subsidiary company, The Winnipeg Rubber Company, Ltd., and in British Columbia through another subsidiary company, the Vancouver Rubber Company, Ltd. The directors and shareholders of the company have now decided that its interests and convenience and the interests and convenience of its customers will be better served by a reorganization which will enable it to operate in all its branches under one name and at the same time adequately care for and develop its very large and constantly increasing business. To this end, application has been made for a Dominion charter under the name "Gutta Percha & Rubber, Limited," with an authorized capital of $6,000,000. The new company will be controlled by the same interests and be under the same management as the old. It will acquire all the trademarks, patents, properties and good will of the old company and, as heretofore, will be an entirely independent concern without connection or affiliation with any other company in or out of Canada.

◆

PAVING CONTRACT.

The Dolarway Paving Company, 95 Liberty Street, New York, have recently been awarded a contract to supply 15,968 square yards of Dolarway Pavement to Roselle Park, N.J., contractors.

◆

NEW INCORPORATIONS.

Calgary, Alta.—Concrete Products, $25,000.

Prince Albert, Sask.—Fuel Supply Co., $20,000.

Moose Jaw, Sask.—Cordova Building Co., $300,000.

Estevan, Sask.—Great West Brick and Coal Co., $250,000.

Redcliffe, Alta.—Redcliffe Pressed [illegible] $150,000.

Regina, Sask.—Crystal Ice Co., $25,000. Rutley Lumber Co., $200,000.

Nanaimo, B.C.—Builders Supply Co., $25,000. Pacific Coast Packing Co., $50,000.

Caledonia, Ont.—Roper Drug Co., $20,000. C. E. Donaghy, J. M. Forbes, J. T. Arrell.

Medicine Hat, Alta.—Medicine Hat Pump and Brass Manufacturing Company, $50,000.

Fort William, Ont.—Eureka Match Co., $500,000. G. W Pepper, O. A. Winter, A. Greengrove.

Minaki, Ont.—Crossing Lumber Co., $200,000. A Stewart, H. R. Patriarche, D. H. Cooper, Winnipeg.

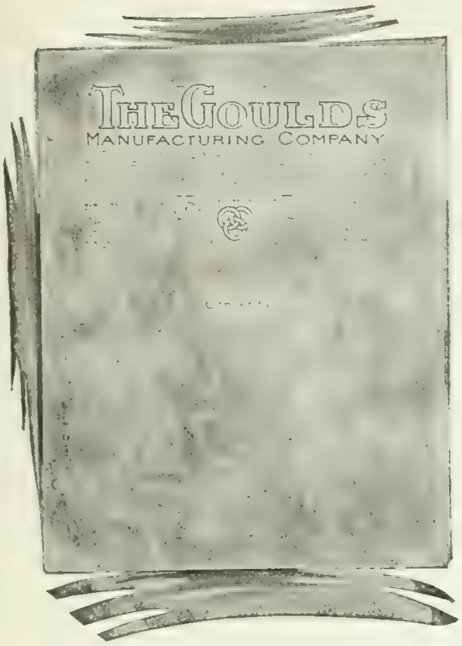
A Data Book that Every Engineer will Appreciate



For the convenience of engineers, contractors and others who have to specify pumping equipment, we have collected all the data and tables needed in pumping calculations.

This data has been published in bulletin form. A copy of this bulletin will be sent on request.

THE FOLLOWING IS SOME OF THE INFORMATION IT CONTAINS—

Instructions for Installing and Operating Power Pumps, Rate of Suction and Discharge, Capacities of Pumps, Dimensions of Wrought Iron Pipe and Well Casing, Table for Equalizing Pipes, Rules for Determining the Size of Pulleys and Gears, Diameter of Pulleys with Belt Speeds and Horse Power Belting will Transmit, Horse Power Shafting will Transmit, Sizes of Triplex Pumps for Feeding Boilers of Various Sizes, General Information on Hydraulics, Friction of Water in Pipes, Discharge of Water, Table of Effective Fire Streams, Weights and Measures, Data Required in Selecting Pumps for Various Services, etc.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

18163—November 28—Authorizing C.P.R. to construct spur for the D. E. Adams Coal Company, Limited, Winnipeg, Manitoba.

18164—November 28—Approving proposed location C.P.R. station at Dorion, Ontario.

18165—November 29—Authorizing Esquimalt and Nanaimo Railway to construct bridge 39.9 on its Comox Extension over Trent River, B.C.

18166—November 28—Authorizing Qu'Appelle, Long Lake and Saskatchewan Railway to construct spur for Cushing Bros. Company, Limited, Regina, Sask.

18167—November 28—Authorizing G.T.R. to construct siding for the Atlas Glass Works, Ltd., on Part Lot No. 130, town of St. Pierre, Parish Montreal.

18168—November 28—Authorizing G.T.R. to reconstruct bridge No. 10, at mileage 8.72, over public road between Cons. 7 and 8, Tp. North Dumfries.

18169—November 29—Approving location G.T.P. Ry. proposed station at Pocahontas, Sec. 6, Tp. 49, R. 27, W. 5 M., Alberta.

18170—November 29—Extending, for a period of one year form Dec. 1st, 1912, Order No. 12723, dated December 6th, 1912.

18171—November 29—Authorizing C.N.R. to divert public road between Secs. 35 and 36, Tp. 41, R. 28, W. 2. M. on its Vonda Northerly Line.

18172—November 28—Authorizing C.N.R. to construct across Twenty (20) highways on its Goose Lake Extension, mileage 281.5 to mileage 301.5.

18173—November 29—Directing C.P.R. to construct a highway crossing over tracks of its Arrow Lake Branch at city Boundary of Revelstoke, British Columbia.

18174—November 28—Approving plan and specifications of Toronto Eastern Railway Co.'s Standard Pile and Frame Trestle.

18175—December 2—Authorizing the town of Bonfield, Dist. Nipissing, Ontario, to construct a highway across C.P.R. on Lot 9, Con. 8, Tp. Bonfield.

18176—November 30—Authorizing C.N.R. to construct across and divert public road between Secs. 21 and 22, Tp. 31, R. 15, W. 4 M., on its Goose Lake Extension.

18177—November 30—Approving location C.N. Montreal Tunnel and Terminal Company, Limited, Railway and Tunnel in city of Montreal, from Lagauchetiere St. Station 13.79.7 to Station 447.17.9.

18178—November 30—Permitting C.P.R., G.T.R., C.N.R., and M.C.R.R. Companies to increase from December 15th, 1912, to March 31st, 1913, both inclusive, the Car Service or Demurrage toll from $1 to $2 a day for first 24 hours, and $3 a day for each succeeding 24 hours, beyond free time allowed by Order No. 906, dated January 25th, 1906, for loading and unloading cars.

18179—November 30—Relieveing C.N.R. from providing further protection at highway about 7 telegraph poles north of mileage 58, Parry Sound Subdivision.

18180—December 2—Recommending the Indenture of Lease, dated October 2nd, 1912, between St. Mary's and Western Ontario Railway and the C.P.R. to the Governor in Council for sanction.

18181—November 30—Authorizing C.P.R. to construct two (2) spurs for the [illegible] Supply Co., Ltd., Winnipeg, Man.

18182—November 30—Authorizing Esquimalt & Nanaimo Ry. Co. to construct spur for the Canada Mosaic Tile Co., Ltd., at mileage 1.7, Victoria West, Esquimalt District, Vancouver Island, B.C.

18183—December 2—Amending Order No. 18024, dated Friday, November 15th, 1912, by changing its date to Saturday, the 16th day of November, A.D. 1912.

18184—November 30—Authorizing G.T.R. to construct sidings for the Dyment Mickle Lumber Co., on Lot 23, Con. 9, Tp. of Fenelon, Co. Victoria, Ont.

18185—December 2—Relieving G.T.R. from providing further protection at crossing of forced road about 1 mile north of Golden Lake, on Lot 5, Con. [illegible], Tp. North Algoma, Ont.

18186—December 2—Directing G.T.R. to construct siding extending southerly from termination of existing siding in road allowance between Lots 4 and 5, Tp. Humberstone, Co. Welland, for Carroll Bros., Buffalo, N.Y., and Sherkston, in Co. of Welland, Ont.

18187—December 2—Authorizing [illegible] Limestone Co., Ltd., to construct [illegible] under the siding of Carroll Bros., on Lot 5, Con. 1, Tp. Humberstone, Co. Welland, Ont.; and repealing Order No. 17007, dated July 12th, 1912.

18188—December 2—Relieving Central Ontario Ry. from providing further protection at highway, short distance south of Wellington, Ontario.

18189—December 2—Appointing and directing Mr. Arthur Sullivan, of Winnipeg, barrister, to make inquiry and take evidence necessary to show whether or not the portion of the Winnipeg Electric Ry., to the C.P.R. shops is profitable.

18190—November 30—Extending, until June 1st, 1913, the time limited by Sec. 4, Chap. 61, of the Acts 7-8, Ed. VII., for approval of White Pass & Yukon Route tolls for telegraph messages between all points in Canada; and allowing tolls authorized to be charged under Acts 7-8, Ed. VII., Chap. 61.

18191—November 30—Extending the tariff of telephone tolls of the North American Telegraph Co., until June 1st, 1913.

18192—November 30—Extending, until June 1st, 1913, the time limited by Sec. 4, Chap. 61, of the Acts 7-8, Ed. VII., for approval of Can. Nor. Telegraph Co.'s messages between points in Canada; and allowing tolls authorized to be charged under said Acts 7-8, Ed. VII., Chap. 61.

18193—November 30—Extending, until June 1st, 1913, time limited by Sec. 4, Chap. 61, of Acts 7-8, Ed. VII., for approval of G.T.P. Telegraph Co.'s tolls between points in Canada, with exception of tolls between local offices, on Ottawa Division, in Ontario and Quebec, and between them and Swanton, Vt., approved by Order 11153, dated July 12th, 1910; and allowing tolls authorized to be charged under Acts 7-8, Ed. VII., Chap. 61.

18194—December 2— Directing G.T.R. to keep all cars away from crossing, just east of Jordan Station, Ont., in both directions for a distance of 100 feet.

18195—November 30—Extending the tariff of telephone tolls of the Bell Telephone Co., until June 1st, 1913.

18196—December 3—Approving location C.N.R. through Tp. 26, R. 7, W. 3 M., Sask., mileage 51.5 to mileage 61.32.

18197—December 3—Approving location G.T.P. Branch Lines Co.'s Moose Jaw Northwest Branch from east line of Sec. 25, Tp. 22, R. 7, to north line of Sec. 31, Tp. 22, R. 7, W. 3 M., mileage 67.86 to mileage 79.02, Dist. Moose Jaw, Sask.

18198—November 30—Extending, until June 1st, 1913, time limited by Sec. 4, Chap. 61, of said Acts 7-8, Ed. VII., for approval of G.N.W. Telegraph Co.'s tolls between points in Canada west of North Bay, also to and from points west of North Bay and to points east thereof, and east of and including Windsor, Ont., and allowing tolls which it was authorized to charge under said Acts 7-8, Ed. VII., Chap. 61.

18199—November 12—Permitting the Winnipeg Electric Ry. Co. to lay and maintain tracks through subway under tracks of C.P.R., on McPhillips Street, Winnipeg, Man.

18200—December 3—Directing C.P.R. to provide a farm crossing in east ½ of Lot 23, Con. 11, Tp. Beckwith.

18201—December 2—Authorizing C.L.O. & W. (C.P.R.) to construct its Glen Tay to Cobourg Line across C.N.O.R., in Lot 28, Con. B, Tp. Brighton, mileage 95.1 from Glen Tay, by overhead structure.

18202—December 3—Certifying that correction, to show station grounds at Bayside, mileage 82.5, in plan of C.L.O. & W., Glen Tay to Cobourg Line, is allowed.

18203—December 3—Authorizing C.L.O. & W. (C.P.R.) to construct across road allowance between Lots 30 and 31, Con. 1, Tp. Hope, mileage 133.38 from Glen Tay.

18204—December 2—Authorizing G.T.R. to construct siding for the Empire Cotton Mills Co., Ltd., on Lot 24, Con. 5, Tp. Crowland, Ontario.

18205—December 2—Authorizing G.T.P. Saskatchewan Ry., to connect its Weyburn Branch with G.T.P. Branch Lines Co.'s Regina-Boundary Branch, in Sec. 35, Tp. 9, R. 13, W. 2 M., at Talmage, Saskatchewan.

18206—December 2—Approving proposed location G.T.P. Branch Lines Co.'s station in Sec. 24, Tp. 1, R. 3, W. 2 M., Sask.

18207—December 3—Authorizing G.T.P. to operate trains over portion of railway between mileage 164 and mileage 176.8, east of Prince Rupert, and amending Order No. 17769, dated Oct. 14th, 1912.

18208—December 2—Temporarily approving G.T.P. Standard Freight Mileage Tariff, C.R.C., No. 12, to apply between stations between Thornton, Alta., and Tete Jaune, B.C., inclusive.

18209—December 3—Authorizing C.L.O. & W. (C.P.R.) to construct across road allowance between Twps. of Haldimand and Cramahe, Co. Northumberland, Ont., mileage 106.17 from Glen Tay; and eliminating Item No. 10 of Order No. 17361, dated August 29th, 1912.

18210—December 3—Suspending, pending a hearing of the application, the rate of 40 cents per net ton, on coal, from Detroit, Mich., to Windsor, Ont., as published in M.C.R.R. Supplement No. 14 to Tariff C.R.C., No. 1288.

18211—November 6—Approving location C.N.O.R., through Twps. York and Scarboro, Co. York, Ont., from mileage 0 to mileage 7.60, from Yonge Street.

18212—November 6—Directing T. H. & B. Ry. to cut down hill immediately east of and south of railway at Gorrie's Crossing.

18213—November 6—Authorizing the London Street Rly. Co. to cross tracks of C.P.R., at Adelaide Street, London, Ont.

18214—November 22—Authorizing G.T.P. to open for traffic its line between Fitzhugh (mile 1027.8) and Tate Jaune (mile 1095.3).

18215—December 4—Authorizing Local Improvement Dist. 18-W. 4 to construct road across Calgary and Edmonton Ry., in east ½ Sec. 20, Tp. 25, R. 28, W. 4 M.

18216—December 4—Relieving B.C. Electric Rly., (Lu Lu Island Branch) from providing further protection at Townsend Road, Mun. of Point Grey, B.C.

18217—December 4—Approving location C.N.R. through Tps. 20-21, Rgs. 21-20, W. 2 M., Sask., mileage 0.00 to mileage 8.79, Craven North-easterly Line.

18218—December 4—Authorizing C.N.O.R. to connect with C.P.R. in Tps. Westmeath and Pembroke, Co. Renfrew, Ont., mileage 82.02 to mileage 82.61.

18219—December 4—Authorizing Can. Nor. Alberta Ry. to operate trains over crossing of G.T.P., in S.E. ¼ Sec. 31, Tp. 53, R. 10, W. 5 M., Alta., for construction purposes only.

18220—December 4—Authorizing G.T.R. to construct siding and spurs for Dominion Wood and Lumber Company, Limited, Lot No. 25, Con. 1, Tp. of Himsworth, Dist. Parry Sound, Ontario.

18221—December 4—Authorizing G.T.R. to construct siding for Kirkfield Portland Cement Company, Limited, at Raven Lake, Ontario.

18222—December 4—Authorizing G.T.R. to construct siding and spur for Canada Grip Nut Company, Limited, St. Johns, Quebec.

18223—November 21—Authorizing C.P.R. to open up Thirteenth Avenue across its tracks and station grounds, town of Estevan, Sask.

18224—December 4—Authorizing C.P.R. to construct spur for Standard Chemical Iron and Lumber Company, of Canada, Limited, Montreal, P.Q.

General Order No. 98—December 6—Directing Railway Companies operating in Eastern Canada, to furnish, according to their respective powers, heated refrigerator cars, during cold weather, for carriage of fruit, vegetables and eggs.

18225—December 4—Directing C.P.R. to install a 12-inch pipe for drainage under its tracks in town of Vaudreuil, Que.

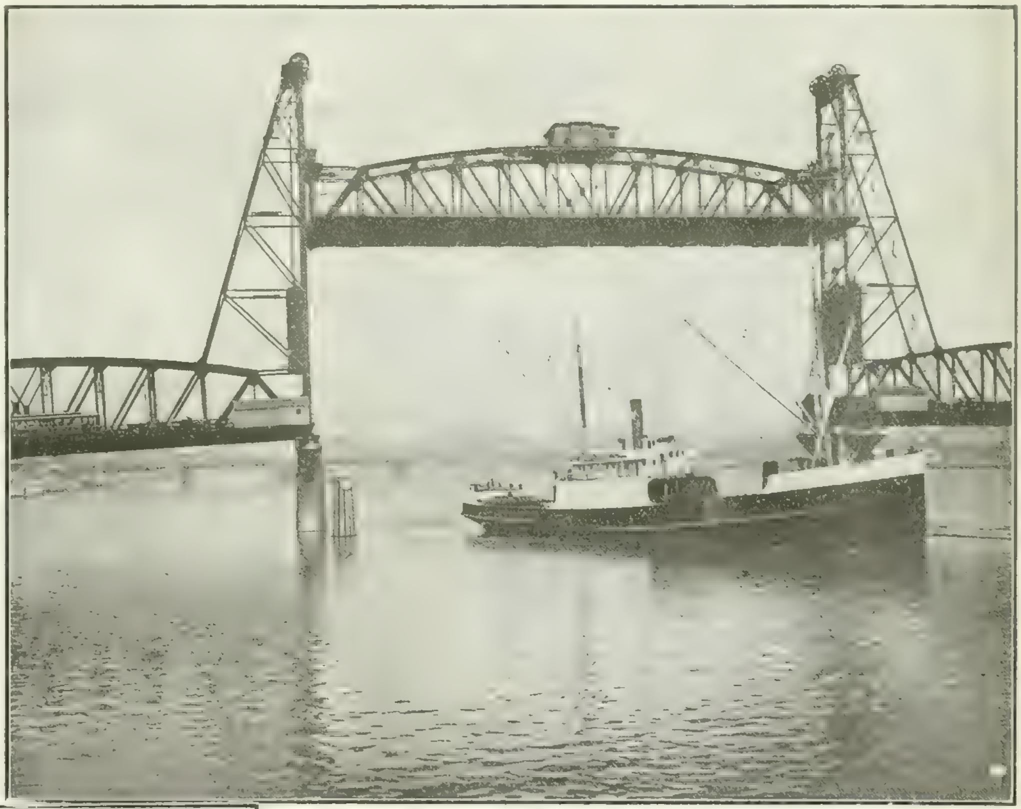
The Canadian Engineer

An Engineering Weekly

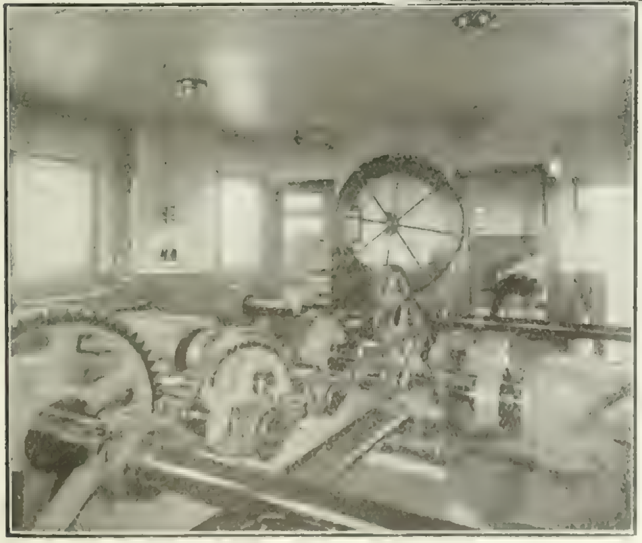
THE ELECTRICAL EQUIPMENT OF THE HAWTHORNE AVENUE BRIDGE, PORTLAND, OREGON.

In laying plans for the installation of a draw bridge for Hawthorne Avenue, Portland, Oregon, the city officials endeavored to eliminate the many vexatious delays that were due to the constant opening and closing of the old draw span type Madison Street bridge, which formerly occupied approximately the same location as the present structure.

After looking over the various types offered, they finally decided on the lift span type as being the one which would most effectively alleviate these conditions. This has proven a very wise selection on the part of the city officials, as the time required to raise the bridge to the top of the span and lower it is less than that required to swing open the draw span type. The lift span type, however, possesses an additional advantage in that it is unnecessary in most cases to raise the span more than a few feet to accommodate the greater bulk of the river traffic, and consequently the delays to traffic across this bridge have been reduced to a minimum.



View of Hawthorne Avenue Bridge, Portland, Oregon,
with draw raised showing boat going through



Interior view of motor house
showing motors and operating gears.

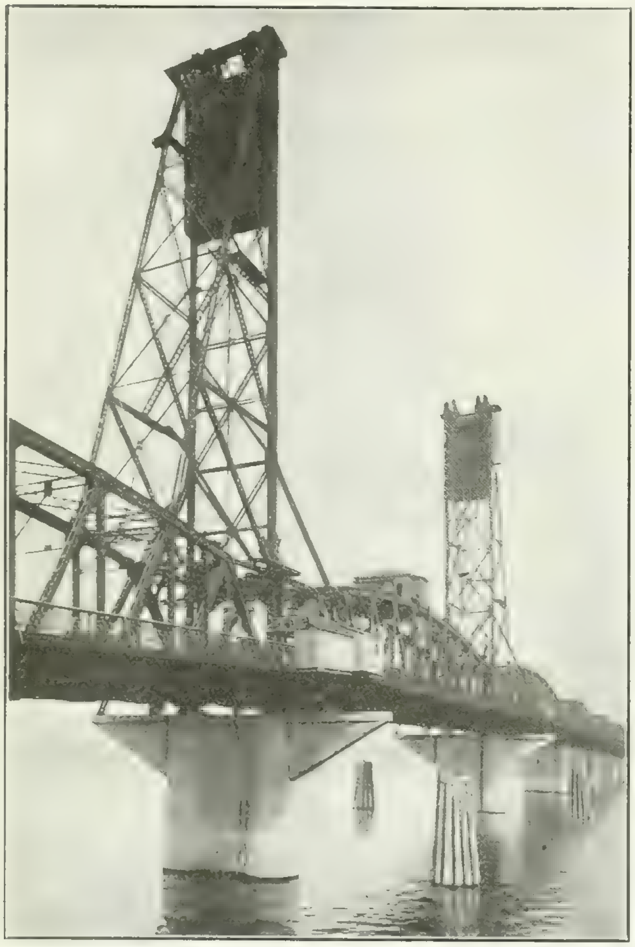
This type of span resolves itself, from an operating standpoint, into practically an elevator proposition, the weight of the span being balanced by means of large concrete counter weights connected to the span by means of steel cables operating over sheaves located at the top of the towers on either side of the span. These counter weights are clearly shown in their position in the photographs.

The bridge is operated by means of two No. 160 Westinghouse 125 horse-power, 550-volt, direct current railway crane type motors, which are directly coupled to a train of gears located in the machinery house on the top of the span; this reduction gearing, in turn, operates the bridge by means of steel cables. The lift span is guided in raising or lowering by means of steel roller bearings operating in the guides located in the vertical uprights of the towers. Besides the advantage of greater speed in operation, and consequently less delay to the traffic, this type of bridge also presents three great advantages from an engineering standpoint.

There is no unequal expansion or contraction, due to the effect of the sun's rays, as would be the case with the draw span type pivoted in the centre.

2nd. The wind friction is practically negligible.

3rd. It offers the use of the entire channel.



View of bridge with draw in position.

The bridge was designed by Waddell & Harrington, consulting engineers, Kansas City, Mo., and was erected under the supervision of Mr. Leon Clarke, engineer in charge. The electrical equipment, including the motors and control equipment, was furnished by Westinghouse Electric and Manufacturing Company, East Pittsburg, Pa.

BRITISH INVENTION FOR UTILIZATION OF PEAT.

A new process for the utilization of peat, invented by F. H. Nixon, of London, consists of cutting the turf, after it has been air dried, into corrugated blocks, which are sprayed with petroleum so as to form firelighters. The blocks are subsequently given a coating of highly inflammable material which also strengthens them and prevents them from breaking easily. It is claimed that this process overcomes the obstacles associated hitherto with the combination of peat and petroleum which have been connected mainly with the employment of a briquetting machine that is not only difficult to work, but also expresses too much of the petroleum from the finished blocks. It is stated that the process enables the firelighters to be produced at a cost which has not been approached before. It is proposed also to employ the method for the production of fuel on a larger scale.

POWER PLANT TESTS.

A valuable contribution to the literature on power station operations is contained in the report of the committee on power tests presented December 5 at the annual meeting of the American Society of Mechanical Engineers. Aside from its importance in establishing standards, the report is a collection of all the information necessary for making a test upon any kind of power-producing machinery, and notwithstanding the vast extent of the field, the report is in most surprisingly condensed form.

The subject matter is divided into three parts, of which the first is a set of general instructions for testing operations. This includes a series of brief descriptions covering the apparatus and instruments recommended for different operations, together with instructions for their use. As an example of the completeness of the report, among the methods described for measuring steam flow is included a table showing the weights of steam discharged through a given orifice with various pressure drops. There are, however, no positive recommendations for smoke determination, although the Ringleman smoke charts and several other methods are briefly described.

Another part of this section is devoted to a statement of the standard units recommended as a basis upon which to express capacities and efficiencies of power generating apparatus. Although the committee recognizes the recently proposed "myriawatt" at a unit for steam boilers by mentioning it in a footnote, in the body of the report the measurement of the boiler capacity is expressed only in terms of the weight of water evaporated from and at 212 deg. per hour. The expression "boiler horse-power" is sanctioned for stationary boilers, but also only by mention in a footnote. Steam turbines delivering mechanical power have been distinguished from turbo-generators in the list of standards by the use of the brake horse-power at the shaft as the unit of capacity for the former and of the kilowatt-hour for the latter. Engine-driven generators are included with turbo-generators, and in both cases the exciter output is excluded from that of the machine.

An interesting recommendation in this part of the report is that covering reserve capacity for power plant apparatus, or, in other words, the excess capacity which it should have over and above the commercial or manufacturer's rating. These reserve capacities are recommended to be 33 per cent. for boilers using standard fuel and 25 per cent. for steam engines and turbines with normal boiler pressure, together with the ability to deliver rated capacity at a boiler pressure 15 per cent. below normal. For pumping engines a reserve power of 20 per cent. is advocated, and the same percentage applies to gas producers and gas and oil engines. Water-wheels, however, are required only to have a reserve of 10 per cent. at the specified head of water.

The second section of the report includes standard codes of rules for different classes of apparatus, each of which is elaborated sufficiently with instructions to enable a test to be carried out in all necessary detail. The individual codes are, of course, revisions of the older standard codes, which are in this report brought up to date and, in consequence, differ but little from the previous form.

The report concludes with a series of appendices giving more elaborate descriptions of instruments and methods that are covered by the first section on general instructions. Among these are several devoted to the analysis of heat losses of the reciprocating steam engine, and a reference is made to the British standard of engine economy, the use of which is, however, made optional in the complete standard code and omitted altogether in the short form.

TOWN PLANNING AND CIVIC IMPROVEMENT.

By C. H. Mitchell, C.E.*

That the towns and smaller cities of Ontario are awakening to the importance and advantages of town planning and improvement is a most encouraging sign of the times. The larger cities of Canada and America generally have already become active in this respect, in practice as well as in the planning itself. They have realized within the past few years that if they are to escape the mistakes of older cities, and if they are to avoid the conditions which make possible these mistakes, brought about by the ever changing modern methods of life and work, they will require to meet the new situation by a rapid change of policy as to transportation, housing and sanitation.

It has become plainly evident that the time is here for national and provincial effort and for concerted civic activity in each community. One does not need to tell the citizens of any town or city in this young country that this movement is vital, in some manner or other, to each community because in this wonderful progressive Canada of ours every month sees the commencement of some little new settlement or hamlet, or the sudden rise of a village to cityhood. And how many of us in the years past, looking each at his own small town, has in his mind, seen it grow to a larger town and then to a city and to a great commercial and industrial community? And how many of the older ones amongst us have seen the dream come true, even in a few decades? And who will foretell for the next few years, and what will he prophesy for that busy part of Ontario which lies between the lakes?

In the larger Canadian and American cities the growth and congestion arising from a rapid development heedless of provision for the future has been recently marked by a sudden realization of the situation and the civic spirit has been aroused. In most large cities nearly everyone—even though he be styled public spirited—has been bent on money-making, an essentially necessary and a practical occupation but a community which is thus absorbed can hardly be expected to give serious thought to the welfare of future generations or to the benefits which might arise from efforts to make the home city attractive to work and live in. Now, however, a change is taking place, and this is evidenced by the fact that over fifty Canadian and American cities have adopted in some degree a course for improvement of existing conditions and systematic plans for the future. In order to provide wide and continuous business thoroughfares, convenient groupings of public buildings, rapid transit, adequate street traffic circulation, parks and squares, parkways and boulevards, children's playgrounds and gardens, clean and attractive streets, pure water supply and efficient sewage disposal, prohibition of sign and noise nuisances, enforcement of laws for structural building and fire safety and for tenement regulation and the encouragement of housing schemes—for all these, enormous financial undertakings are being projected.

Civic effort toward future planning and improvement, while it may be encouraged ever so much in each community, cannot in itself succeed sufficiently to meet the present-day conditions. Such effort must have encouragement from higher up and from the mutual assistance of sister towns and cities, in educating the people and in impressing upon the Provincial and Dominion authorities the great desirability of legislation designed to encourage, if not assist, various kinds of civic improvement which otherwise might not be rendered possible. This, I take it, is the spirit which brings together at this spontaneous and self-appointed inaugural congress, the many officials and citizens of the cities and towns of Ontario, and it is with such an object that, doubtless out of this meeting, some permanent organization will arise to inquire into the present situation and carry the movement to some conclusion.

Toronto, the "Queen City" of the province is becoming more and more interested each year in practical civic improvement and planning according to the general acceptation of the term. While many of the civic authorities are fully aware of the importance and necessity of changes and provision in anticipation of the future, it has been found that the most effective means of obtaining real action and conclusive legislation by the city government has been through the medium of citizens' organizations such at the "Civic Guild," the "Board of Trade" and the various Ratepayers' Associations which are spread over the city. These bodies have been enabled to study various civic problems without the distorting vision of the prospective candidate for municipal honors at the coming January election, and have brought to bear pressure from the outside, toward improvements either for the immediate present or the future which otherwise would have been overlooked or been incapable of realization owing to local or fractional opposition in various parts of the city. The Civic Guild, which has an active executive committee including prominent business and professional citizens meeting weekly, has been especially making a study of the needs of the city in this respect and has succeeded in inaugurating and in bringing about a great many improvements which all thinking citizens united in approving and supporting. Out of the efforts of the Guild grew the Civic Improvement Committee, appointed by the mayor in 1911, for specially studying and outlining a comprehensive system of civic planning; this report recommends and the Guild strongly urges a permanent commission for the city "clothed with the necessary powers for carrying out a broad, sane and comprehensive scheme of civic improvement."

The general subject of civic planning, which is really as old as the hills and not a recent development, embraces all of those allied subjects such as street routes and widths, depths of blocks and lots, buildings, street circulation and transportation, housing with its light and air problems, sanitation and cleanliness, railroad locations, distribution of factory areas, parks, playgrounds, boulevards and in general all those matters which influence the lives of the people in the community. The ideal, therefore, of city planning is that in which all these branches are harmonized to secure for the people of the city such conditions as will obtain a maximum of efficiency in work of health of body and of enjoyment of life; in other words, to make the city a good place to work and live in.

It has been a common idea in American cities until quite recently that city planning has been almost exclusively identified with city beautifying. This view is not fair to the whole subject because it loses sight of the practical sides of the question, which are very many and complex, as can be readily seen. City planning should mean the acquiring of a city convenient, useful, economical and healthful, as well as a city beautiful

Civic planning may be divided into three general divisions as affecting the city or town within its boundaries, with perhaps a fourth as affecting it from the outside. These are as follows:—

I. The first division is concerned with the circulation and transportation problem within the city, and embraces roads, railways, waterways and all means of communication.

---

* Vice-president, Toronto Civic Guild, member Civic Improvement Committee, of Toronto.

II. The second division concerns all other public areas and buildings not devoted primarily for circulation, and would embrace firstly, such institutions as municipal buildings, schools, post offices and government buildings, hospitals, libraries, museums, churches, public halls, theatres, all of which have more or less land space surrounding them, and secondly, parks, gardens, highways, boulevards, playgrounds, amusement parks, cemeteries, etc.

III. The third division relates to all of the remaining or privately owned lands within the city, and concerns more particularly the character of their development in so far as the community can control, especially as to buildings, sanitation, fire risk, density of population, adornment as to trees, gardens, etc.

IV. A fourth division may very rightly be added to the foregoing, which concerns those areas and features of development lying outside the boundaries of a city in which the city is vitally interested, but over which it probably has no control, except through some higher authority such as the province.

It is not the purpose here to describe in detail the features of the various branches of civic improvement enumerated, but rather to draw to your attention the outstanding problems which are confronting our municipalities, large and small, and more especially those which now, or may in the near future, concern the cities and larger towns of Ontario. Following out these divisions we have:—

I. Division—Circulation and Transportation.

Street Planning.—Street planning in the full sense is the key of the whole subject, whether considered from the strictly practical or the artistic standpoint. After all, the primary principle, and the principle which is the very basis for the existence of cities is the facility of communication, and a city is probably more dependent upon this facility for its prosperity than upon any other physical factor under its control. This can be fully realized when it is considered that three-quarters of a city's traffic is either to or from its general centre.

The area allowed for streets in most cities aggregates at least 25 per cent., but there has been a pronounced tendency of late, even in Ontario, I am sorry to say, to reduce this in outlying portions by sub-divisions in residential districts which are placed on the market by proprietors and agents interested only in the selfish business of selling the lots. These proprietors—still absorbed in money-getting like their predecessors—have in most cases no interested desire to promote the common welfare of the citizens, and do not interest themselves in easy communication, but rather adopt any haphazard layout suitable to the plot of land they happen to have which may appeal to the temporary convenience or fancy of the prospective inhabitants.

Probably the worst fault with our early planning for cities has been the adherence to the "grid-iron" layout. There was a time when this was boasted of as the ideal system and even to-day it is being blindly followed in some of our western cities. It may have done in the days of the Romans and during last century in America, but this is the century of rapid transit and present-day automobile and motor truck transportation demands rapid circulation with the fewest corners and the fewest delays in traffic. Interesting examples of the avoidance of the "grid-iron" are the radial and fan-like systems which have been employed in the great European capitals, such as London, Paris, Berlin and Vienna, in America in Washington, and now in Australia, where the plan for the new Federal capital, about to be built, embraces several hub-like centres with radiating streets.

The obvious remedy for the "grid-iron" system after having been once established is the introduction of through diagonals, superimposed upon the "grid-iron" in order to facilitate rapid transit to the four corners of the city in addition to the four sides. This is the course proposed and in some cases being followed in various cities where the "grid-iron" routes zig-zagging back and forth on the two sides of the triangle have become intolerable under modern conditions. It is the proposal of the Civic Improvement Committee for Toronto to open diagonal streets northeast and northwest from Queen Street, near Yonge Street; these would rapidly serve the growing population in these corners of the city and their suburbs, and would carry traffic beyond the upper Don on the one side and the upper Humber on the other.

Street Widening.—Closely allied with the actual layout arrangement of streets is the question of their width. In the early days in Ontario nearly all streets, without regard to their probable uses, were laid out a uniform width of 66 feet, probably for no other reason than because it was convenient, being the length of a surveyor's chain. You who lived with this system know how it has worked out. Hardly ever can it be said to be too wide, because if in residential quarters the space not actually occupied in roadway can be profitably laid out with grass and trees. On the other hand, how often nowadays is it not found too narrow, even in our towns on the main business streets where traffic, moving and stationary, accumulates and congests and consequently delays the free course of business. In a recent report on an American city an eminent town planning expert states that "every delay in traffic adds to the expense of manufacturers, the cost borne by wholesale merchants and the prices charged consumers by retail merchants; in short, inadequate traffic facilities add to the cost of doing business and of living."

Three factors may be said to enter into the determination of street widths on business thoroughfares: Pedestrian traffic, vehicular traffic and street car traffic. On a main business thoroughfare in a large busy city it has come to be an accepted principle from the necessity of modern traffic that there should be sufficient space between the centre line and the curb for a street car line and three lines of traffic, one standing at the curb, one slow-moving and one fast-moving. If, in a busy retail store district, four lines of pedestrian traffic are provided for in each direction on each side a 16-foot sidewalk would be required. This brings the total width of such a street to 104 feet. If one of the three vehicular traffic lines were dispensed with on each side the width could be reduced to 86 feet, which is the absolute minimum sufficient under present conditions for down-town business streets having two lines of street cars and streets crowded with vehicles and pedestrians. So apparent and acutely has this been brought home to Toronto citizens, where the space for vehicular traffic is so narrow, that an automobile and street car cannot simultaneously pass a standing vehicle, that the civic authorities have been compelled to pass a by-law prohibiting automobiles passing a standing street car whilst loading its passengers. It has also been necessary to prevent vehicles of all kinds standing an undue length of time at the curb.

What is the result? Cities which are now feeling the pinch of narrow 66-foot business streets, and those cities ambitious to have attractive and convenient business streets in the future are quickly and seriously considering how they may widen their busy thoroughfares by at least an additional 20 feet either on one side or both. How this can best be done on streets already built up with stores and fine buildings is engaging the attention of town planners and civic authorities throughout the continent. Two methods have presented themselves. One, the establishment of a new line called the "homologated line," to which all new buildings as built will be moved back, and the second the establishment of such a line to which, at some future date many years distant, all buildings must be moved back. In the former case the cure is unsatisfactory, as has happened in Montreal, because new buildings built to the new line become "pocketted" between adjoining old ones, and thus, if they are stores, may temporily lose trade. The latter method is the one recommended by the Civic Improvement Committee of Toronto, and provides that after the new street line and a date, say, 20 years hence, are fixed, new buildings may proceed on the understanding that at the stated date the added strip will be purchased by the city at the price obtaining at the date of enactment for, say, only two or three stories of the building which must be torn away from the front. Such an arrangement makes easy construction and automatic land purchase by the city at a reasonable price, the owner having the use of it in the meantime.

Rapid Transit.—It is not the purpose here to enlarge upon the conditions brought about in civic matters by the introduction of rapid transit, either within the city and its suburbs, or outside the city in interurban traffic. The great tendency for people to live in the suburbs and country is to be noted, however, and the effect of this daily migration more than ever intensifies the traffic congestion within the city. It is a question, too, whether it does not increase the cost of living if there are not convenient and adequate facilities through the city streets for delivery of goods and supplies.

Railways and Waterways.—In olden days, when cities were walled about, the entrance was through elaborate and artistic gates which gave to the incoming visitor his first impression of the town. Nowadays, our gates are our railway stations and our harbors. These are the entrances, and from these our visitors receive their first impressions and judge of us. Too often do the railways approach our towns through dirty back streets, ill kept and unattractive, if not repellant. How many of our railway stations are situated in unattractive quarters of the town amongst surroundings which, with some attention from the civic authorities and public-spirited citizens, can be made to look inviting and cheerful to the incoming visitor. The railway companies are beginning to do their part by the beautifying of their own station grounds by gardens and lawns. It is the duty of the citizens to help.

The same holds true for our docks on our lake and navigable river gateways—perhaps the possibilities are not so apparent because each town has its own specific problems. The outstanding instance of this movement is the truly magnificent scheme which the harbor commissioners have outlined for the development of Toronto harbor which, when completed, will without doubt be at the same time one of the most attractive as well as serviceable harbors in the world.

Street Improvement.—Amongst the many things which can be accomplished by civic authorities in making a city attractive is by clearing the streets of various obstructions on business streets and by preserving the trees in residential streets.

The removal of electric wires and their forests of poles can be accomplished by placing them either on alleys or side streets of by meeting the question squarely and putting them underground, on the principal streets at any rate. This would then help to preserve the trees in fine residential streets where too often the tops and centres of fine trees are brutally cut away by linemen. The removal of unsightly signs overhanging or prominently situated on or near streets is possible, if concerted action is taken by determined citizens. The encouragement of planting trees and flowers and of sodding on residential streets commends itself, as does also the placing of fountains and watering places. Artistic bridges in the suburbs as well as in the centre of the city are just as easily and as cheaply built as heavy formal structures, and make a street more attractive, particularly if finished with neat balustrades and lamps. Street lighting, especially where the hydro-electric power system throughout the province provides such a cheap and convenient source of electricity, lends itself, as hardly anything else can, to the ready adornment of streets, either business or residential, if the individual lighting scheme by using lamp posts is carried out artistically. And one might go on to all the various street features, such as walks, curbs and pavements and make a plea for clean-cut, well-planned improvements, all of which are just as possible in the smaller cities as in the larger. And, after all this is done no community can have any excuse for permitting its streets to become unsightly with flying papers or other rubbish, and all citizens will have sufficient civic pride to see that their streets are kept looking attractive.

II. Division—Open Spaces and Parks.

When we think of city parks and open spaces we must think of them as utilitarian as well as beautiful—for we must have parks and recreation spaces and breathing places if we are to have happy, healthy and contented citizens. It is not necessary to dwell on the various attractions or valuable features desirable within the parks themselves, but the great question which is interesting all civic authorities nowadays is how to make the parks more accessible to the people; how to get them properly located, and whether it is possible to get them connected up one with the other by an elongated park or parkway, or by a combination of street and park termed a boulevard. This is the day of the electric street railway and of the automobile, so that the total distance to be travelled is not so much a matter as the advantage of getting quickly amongst trees and flowers and greenery as a relief from the hot and dusty working city. The parkway and tree-planted boulevard meet this demand and are to be commended as linking up several parks or open spaces as they bring the parks, so to speak, nearer the people's doors.

But all do not travel or have not the time or opportunity to travel in street car or automobile. For these and for down-town uses there must be small street corner parks or rest places with trees, shrubs and flowers.

All the principal public buildings, such as have already been enumerated, should be set, if possible, in fine, open spaces, not only to show them off to advantage architecturally, but in order to provide a suitable park and garden setting.

This brings us to the question of a grouping of public buildings in a convenient central location which has been called "The Civic Centre," and which is an ideal to which many large cities are aspiring. This, after all, is nothing much more than the old town square or market place of the early days, but now on a gigantic scale. The civic centre idea is being adopted in many American cities as being not only of utilitarian convenience, but best calculated to centralize civic activities and foster civic spirit. This is the scheme which has been proposed in Toronto by the Civic Improvement Committee for a grouping of municipal, county, provincial and federal buildings in one locality north of Queen Street and between Yonge Street and University Avenue. Within the heart of many of the Ontario cities there is a space which, it appears, has been going through a period of neglect the past few years—the market. It may be because of the changed transportation methods, or because of the roads leading in from the country, or the changed methods of marketing, but if a market is to be maintained duty still remains with the city authorities to make the market and its appurtenances and the streets leading to and about it attractive and convenient for carrying on trade under the new conditions. In these days of inquiry as to "The High Cost of Living," it appears to be of vital importance that farm produce and the other necessities can be marketed directly from the producer to the consumer in the easiest and quickest manner possible.

Other open places, such as playgrounds, gardens, recreation and amusement grounds are quite as necessary for our young and old as are schools, churches and hospitals, and the value, for instance, of supervised playgrounds and children's gardens to the rising generation, cannot be over estimated. In this respect the education of the young generation, and the old, for that matter, is of vital importance toward the preservation of trees, grass and flowers in public places.

There are doubtless many other miscellaneous areas and spaces within our home cities which, though now neglected and unattractive, might readily lend themselves to artistic and useful development. Such spaces may be peculiar to the natural situation of the city. It may be a creek or a river; it can be cleaned, old tumble-down buildings removed, the sides banked up and the shores planted with trees and grass. It may be a wooded valley; it can be cleaned of its refuse heaps, the wooded slopes preserved, the underbrush and stumps removed and the whole brought cheaply into a new park. It may even be an unsightly abandoned quarry; a little money spent on earth filling, walks and gardening might make it into an attractive garden. Or, it might be a winding sylvan roadway on a hillside; it can at least be kept clear of weeds and loose stones.

A picturesque valley can, at small expense, be utilized for a parkway and its drives terminate in terraced parks or connect various garden centres of the town. In some of the Ontario towns there are rivers which, on account of their annual freshets, discourage an attractive treatment of their banks—this is all the greater reason for these towns uniting to bring about conservation methods to prevent these floods; the banks within the towns could then be trimmed up with walls and the buildings upon them reconstructed in a permanent artistic manner. If factories must be on the river bank, they can, by the utilization of electric power, avoid, or at any rate, mask the unsightly ash and refuse dumps which are so common. To carry this idea still further, how much more attractive a river could be if it had a water-front space, its outer walk forming, wherever possible, a tree-shaded promenade provided with benches and other features of recreation?

III. Division—Privately Owned Lands.

At first glance it might seem that in a new democratic country like ours the municipality would have but small control over privately owned lands and their buildings and occupants. In a measure this is true, but as time goes on and we work out our various problems of civic government, be they in large or small communities, we have found that many measures must be framed by the people themselves in self-defence and the common interest.

The most important of such measures are, of course, with reference to health and sanitation, a discussion of which is not intended here except to draw attention to the necessity of regulations against overcrowding of houses and factories. The housing question is quickly becoming acute in large densely populated cities where industrial workers are crowded into areas and buildings in proximity to their work. While this question perhaps does not concern the younger and smaller cities in general, it has an interest in particular to those cities which have a proportionately large industrial population, such as have many of the Ontario towns in the hydro-electric power area. In these towns the municipalities can at least encourage in every manner possible the making of attractive, healthy and comfortable homes by the working people. This, as everyone knows, should be encouraged in every possible way by the employers—the manufacturers themselves—to ensure their work-people being contented and efficient. "Garden Suburbs" for working men can be readily organized and should be attractive and worth while for these smaller cities whose population is largely industrial.

On residential streets much attractiveness can be added by placing restrictions to keep the houses back a definite distance from the street and by encouraging tree planting and sodding the space both on and off the streets. Window gardening should be encouraged, especially on those streets where the houses are close to the sidewalk. Legislation is already provided for keeping houses back of the street.

The municipality can very much improve the city in its attractiveness by passing and enforcing regulations for smoke prevention and for removing noise nuisances—such as train whistling—and by discouraging unsightly sign boards on private property.

Reference has already been made to the selfish methods of many landowners in opening up their new sub-divisions. They should be prevented, if possible, from dividing residential property into individual lots too small or of unsuitable form for gardening and planting as is frequently the case, and they should be encouraged to place restrictions upon the locations of houses on their lots. It would not be amiss here to draw attention to the frequent misrepresentation of the location and features of sub-divisions placed before the public which has become so common of late, not so much in Ontario as in the West. While everyone admits that the speculative holding of land within a city is a detriment to its growth, no effective or equitable legislative measure to prevent it is yet apparent, unless it be by the whole reconstruction of our taxation system.

IV. Division—Land Outside the City.

Under modern conditions of transportation and the inevitable expansion of suburban areas outside of the small as well as the large cities, we must at once become interested in the development of the country surrounding the city.

There are two vital points which arise. The city authorities—as distince from the township—have under our present laws, no control over the layout of sub-divisions immediately adjoining or outside the city limits; they cannot, therefore, co-ordinate street planning or street widths with those inside the city, which is an absolute necessity. The city, moreover, does not exercise any control over such questions as park and open space allowances in such sub-divisions.

The arrangement and improvement of township and county roads not only to make them easy and convenient for transportation, but attractive as interurban drives and parkways, is of special interest to a city or group of cities, providing, as it would, a ready means of bringing farm products into town as well as convenient interconnection between towns. This would have a direct bearing on the cost of living and the attractiveness of a group of towns, and of the intervening country as places for residence and business. A noteworthy example of this development on a large scale is the Essex County park system in New Jersey.

Conclusions and Recommendations.

The cities and towns of Ontario, and especially those in the area between the Great Lakes, stand unique in Canada as being so grouped and favored by location as to benefit from hydro-electric power for industrial purposes. They become, in addition to their former activities, each a special industrial centre and their future depends much on this ability to expand while retaining attractive homes for their workers.

In this review of the subject of civic improvement many of the illustrations and the motives have been drawn from the experience and activity of the larger cities but, as has been pointed out, there are very many openings for the adoption of similar improvements and projects in the smaller towns and cities of Ontario. These cities can still be unique by leading in town planning and improvement as well as by leading in industrial activity.

Each city has its own specific outstanding feature. It may be its geographic situation or its transportation facilities, or its contiguous country. It may be some physical feature of landscape—a hill, a valley, a river, lake or waterfall. Whatever these features may be they can all lend themselves to practical utilization, combined with artistic and pleasing attractive treatment.

You who live in these towns and cities can, by taking thought, suggest lines along which your particular civic improvement might follow. Your civic officials, energetic and able though they may be in their proposals for improvements, probably have their hands tied by lack of public support and certainly they are powerless through inadequate laws. The civic authorities require more power and the citizens more understanding and education as to the benefits to be derived.

Much of the momentum for a movement of this character must come from the citizens themselves and from a sympathetic press which fully grasps the significance and advantages of the movement.

In order to inform and educate all our citizens it would appear that in each city, as a neucleus, a small committee or commission should be formed for the purpose of making a study—a stocktaking as it were—of the possibilities which present themselves. They might be improved, if it was thought expedient, to call in an expert to advise either on a comprehensive scheme or upon some particular detail. Any schemes arising from this preliminary study might then be discussed by the civic authorities and the citizens and some improvement programme laid out either in detail or in a comprehensive manner which might be spread over a number of years, but always conforming to a prearranged systematic plan which, when complete, will stand the city for all time.

It will, of course, be asked how such projects could be financed. The municipality may devote a definite portion of its tax rate each year for the purpose, in which each year's levy would be used for the upkeep and improvement of existing works, and for the purchase of new lands and for the construction of new works. Toronto has adopted this principle for its parks.

If it was possible to capitalize a yearly sum or a portion of it, and suitable legislation could be obtained, a capital sum might be raised by debentures and the proceeds devoted to a new work and purchases of lands, the whole managed and controlled by a special commission apart from the city council, which would be a body of a more permanent personnel. One of the great advantages of such a commission would be that it could enter into real estate transactions without publicity, and thus save money which could be put into actual improvements. Such a commission would require to be invested with special powers by the Legislature to enable it to carry on the financing of such projects; the relations of such a commission to the Ontario Railway and Municipal Board would require to be clearly defined.

For the purpose of giving effect to any proposals which might be made as a result of this and other conferences of representatives of the various municipalities of the province in seeking necessary legislation and outlining a course of action, it would seem advantageous to appoint a committee sufficiently representative to embrace the various phases to be considered.

In view of the experience acquired in the study of these questions in Toronto, and in view of the situation existing throughout Ontario it would appear opportune for the municipalities to seek, through their committee, such legislation as would facilitate those civic improvements which may be desirable. This legislation might include amongst other enactments:—

Provision for civic improvement commissions in the smaller cities.

Provision, applicable to cities smaller than already provided for in the Ontario Act, for the purchase by municipalities of lands required for opening streets, not only sufficient for the streets themselves, but for an adequate margin on each side which, after the opening has been completed, can be resold as lots, thus producing a revenue to help meet the cost of the improvement.

Provision for municipalities to secure streets wider than 66 feet on new subdivisions when necessary to conform to a town planning scheme.

A practical method for any necessary widening of business streets already built up.

An adequate control over new subdivisions so that the layout will conform to modern requirements and so that misrepresentation cannot be practiced. The embodiment of ininformation such as contours and elevations is to be recommended.

Provision for the control, through the Ontario Railway and Municipal Board, by the municipality of the layout and street planning features of subdivisions outside the city limits for a stated distance.

With respect to the two last proposals the act passed by the Legislature at the last session provide for control by the board of street planning and the size and form of the lots in subdivisions, both within and for five miles outside, of cities "of not less than 50,000" population.

◆

TESTING A CONCRETE BRIDGE.

On a bridge recently completed in England, a rather unique test was carried out. The bridge was loaded with water. The floor system of the bridge is carried by columns on three reinforced concrete arches. The clear span is 57 feet, and the rise 8 feet 3 inches. The parapets are solid concrete with sunken panels. In preparing for the test, a clay dam 3 feet thick at the base, and 1 foot thick at the top, was built at either end, and the water was conveyed through a 2½-inch hose. The load was applied in 8 hours, and although it exceeded the required loading of 250 lbs. per sq. ft., the deflection at centre was only 1/16 inch. The water test load was rapidly and easily applied and removed, at a very low cost. It would be a very easy matter in situations where water service is not available to pump water from the stream which the bridge spans.

STRUCTURAL-STEEL TOWERS AND POLES.*

By R. Fleming.†

Wood, Concrete and Tubular Poles.—According to the United States Census there were 3,870,000 wooden poles purchased during 1910. Of these 62% were cedar, 18% chestnut, 7% oak, the remaining 13% being pine, cypress and other woods. Classified according to length 17% were under 20 ft., 56% were 20 to 30 ft. (this being the length most commonly used by telegraph and telephone companies), 21% were from 30 to 40 ft., 5% were from 40 to 50 ft. and 1% over 50 ft. The bulletin from which the above statistics are quoted gives the number of poles purchased in 1909 as 3,738,000; in 1908, 3,249,000; in 1907, 3,283,000. Of the poles purchased in 1910 about 21% received some kind of preservative treatment before being set in place.

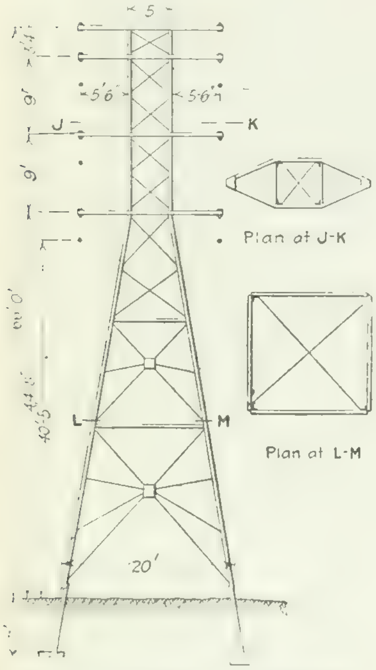

Fig. 1.—Standard Transmission-Line Tower, Connecticut River Power Co.

For 1909 the average first cost of wooden poles purchased was but $1.89. So, from the financial standpoint nothing has been found to take the place of wood for the ordinary telegraph or telephone line pole. The cost of renewals and maintenance is not great enough to warrant the additional first cost of either concrete, iron, or steel poles, and wood will continue to be largely used for some years to come.

Wood is increasing and fabricated steel is lessening in price. Fewer poles or towers are required if made of steel than of wood as they can be placed farther apart; this means fewer foundations, crossarms and insulators. In many cases, as for distribution systems in the yards of shops, wooden poles are not strong enough to carry the loads that will come upon them. Municipal authority has sometimes required the wooden pole on the city street be replaced by the steel pole. The fire risk is eliminated with the steel support, and this is important. A substitute for wood is therefore in many cases not only desirable, but necessary.

Reinforced concrete is being used to some extent for distribution lines of electric-light and power companies, and also for overhead construction of street railways. The general tendency seems to be in the direction of a more extended application.

Tubular poles, made of successive lengths of iron pipe, take up little room, present a round resisting surface to external loads, show excellent results when tested, and can easily be repainted when necessary. Their limitations as to size restrict their use to light loads.

Structural-Steel Towers.—This paper will be restricted to structural-steel supports—either poles or towers. The treatment of reinforced-concrete poles, tubular poles, or the different patented poles on the market will be left to others. The literature on steel towers is extensive—that on steel poles is limited.

We have yet no form of either pole or tower that can be called "standard." Present-day practice for poles is crystallizing about the latticed four-angle type. Towers are being built mostly of the square wind-mill type. An exception is the 140,000-volt line put in operation this year in Michigan, where the towers, of which there are 10 to the mile, are of the braced-tripod type, composed entirely of galvanized-steel angles. This line, at present 125 miles long, is being extended a hundred miles farther and carries the highest voltage yet undertaken, the previous maximum being 110,000 volts.

While the electrical features of a transmission line have received careful attention by the electrical engineer, the structural features have often been taken care of in a crude way, or left largely to chance. The electrical engineer fails sometimes to realize there are other problems to be solved besides those of a purely electrical nature. He should work with his brother, the structural engineer, as the chief item of cost in a transmission line is the structural-steel supports.

Loads.—In designing either a pole or tower the first question for determination is the loads to be carried. These loads are of three kinds: (1) Vertical or dead loads; (2) loads at right angles to the direction of line, due to lateral wind pressure; (3) unbalanced loading in the direction of the line, due to breaking wires. The forces of these three loadings are at right angles each to the other.

(1) The vertical or dead loads are: (a) the weight of the structure itself; (b) the weight of the wires supported by the structure; (c) the weight of the snow or ice coating, if any, on the wires. In sleet regions, ice is generally assumed to accumulate ½ in. thick around the wire. These vertical loads are easily determined, but are seldom a governing feature in the design of the structure, except for the crossarms. The crossarms should be designed for a minimum load of 1,000 lb. at each end. They carry not only the insulators and wires but at times a man or two to adjust them.

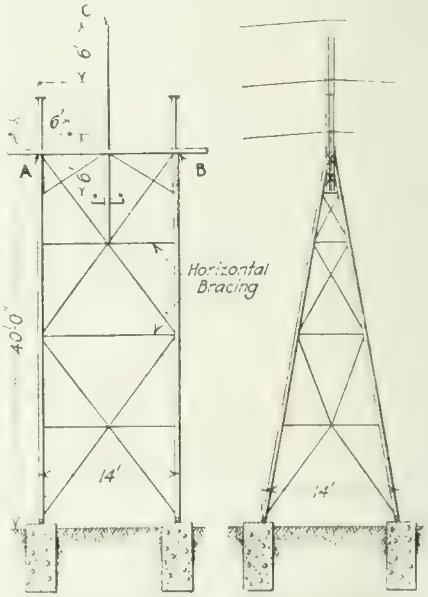

Fig. 2.—Standard Structural-Steel Tower, Georgia Power Co.

(2) The lateral wind pressure on transmission lines has been much discussed. Well known engineers have arrived at widely different conclusions. The author of the article on "Electrical Power Transmission in the Encyclopedia Britannica" writes:

> The actual possibility of wind pressure is very generally over-estimated, and has resulted in much needlessly costly construction.

---

* From a paper presented at the annual convention of the Association of Iron and Steel Electrical Engineers, Milwaukee, Wis., September 30 to October 5, 1912.

† American Bridge Co., 30 Church St., New York City.

Another writer (Joseph Mayer, Engineering News, Jan. 4, 1906), says:

Such lines should, therefore, be built strong enough to resist not only the commonly occurring, but also the exceptionally violent local storms.

From a mass of data, the writer recommends the use of the following wind loads: (a) On the structure itself, 30 lb. per sq. ft. of exposed surface; (b) on bare wires, 15 lb. per sq. ft. of projected area (length multiplied by diameter); (c) on wires covered with ½-in. coat of ice, 10 lb. per sq. ft. of projected area. In a sleet region (c) should be followed as it is the more severe.

It is noted at once that the requirements given for (1) and (2) do not in themselves determine the loads on the towers or poles unless their distance apart is known. In laying out a transmission line the first thing to find is the most economical span. This is both an electrical and a structural problem. The voltage, size and kind of wires, are to be decided. With these given, the spacing of towers can be determined. The foundations also enter in the calculations. Empirical formulas have been given for the most economical span, but so many variables enter into the question, that they can only be regarded as approximate. Each line is a problem by itself and must be solved independent of all other lines.

(3) The assumptions regarding unbalanced loading in the direction of the line will often determine the design of the tower. Practice as well as theory varies widely in this respect. The following is recommended: A tower having three line conductors or three conductors and one ground wire should be designed to withstand the unbalanced load due to any single wire breaking; a tower, having six line conductors or six conductors and a ground wire should be designed to withstand the unbalanced load due to any two wires breaking. The breaking of a wire throws upon the wire in the adjacent span and thence to the tower a load equal to that which caused the wire to break. For the smaller sizes of wire, No. 4 and under, this load should be taken as the ultimate strength of the wire itself. For No. 3, 90%; No. 2, 80%; No. 1, 70%; No. 0, 60%; and for No. 00 and larger wires it is recommended that 50% of the ultimate strength of the wire be used. The reason for the larger wires being given an advantage is that a break is not liable to occur in them until there has been a reduction of cross-section from burning due to a short-circuit from any cause. The smaller sizes will not permit any reduction of section without breaking.

For line conductors hard-drawn copper wire is generally used. The American Steel & Wire Co. find, from tests, the elastic limit of their copper wire to be 34,500 lb. per sq. in. and more and the tensile limit from 50,000 to 65,000 lb. per sq. in. For No. 00 copper wire, a size often used, the longitudinal pull due to one wire breaking will be 2,500 lb.; for No. 0000 copper wire 4,000 lb. will answer. Care must be taken to provide for torsional stresses caused by unbalanced loading.

In designing the standard towers of the line, the material is to be proportioned for maximum stresses due to any combination of loads (1), (2) and (3).

Unit Stresses.—Equally important with assumed loadings are assumed unit stresses. It might be well to divide proposed towers into three classes—(A), (B) and (C), and assume unit stresses in accordance with the classification of the tower. Two prominent features to be considered regarding any line are the importance of uninterrupted service and the probability of loss of life, due to accident of wires or towers giving way. If the purchaser of power insists upon service at all times under heavy penalty, the tower would come under (A). If interruptions under certain limitations are allowed, (B) may answer. From the standpoint of loss of life due to accident, a line over a thinly settled mountain country would come in (B), while the thickly settled zone about a town or city would require (A). Using open-hearth steel with an ultimate tensile strength of 55,000 to 65,000 lb. per sq. in. and an elastic limit of 55% of the ultimate strength, the working unit stress of steel in tension may be taken at 22,500 lb. per sq. in. for (A) and 27,000 lb. per sq. in. for (B). For steel in compression the recommended formula is:

$$\frac{22{,}500 \text{ or } 27{,}000}{1 + \dfrac{l^2}{18{,}000\, r^2}}$$

To (C) is consigned poles and towers where the primary feature to be considered is the cost. The question then too often becomes, not what the structure should be, but what are the least requirements that can be exacted and the line probably do its work. A common method of reducing material is to consider loadings (2) and (3) not acting at the same time, and increasing the unit stress to 30,000 lb. per sq. in. Some engineers think a high wind will not occur when the wires are covered with sleet.

Even admitting this to be true, arcing sometimes happens between wires when there is a high wind on the bare wires. Owing to lightning discharges, accompanied with wind, it may happen over insulators. This is certainly a combination of (2) modified, and (3) which should not be neglected. For wires covered with ½ in. coat of ice, 8 lb per sq. ft. of projected area for wind load is considered allowable by some good authorities. To this there is not the objection as to the use of 30,000 lb. per sq. in. for unit stresses. The latter comes too near the elastic limit of the steel likely to be used.

It may be said here that comparatively few existing towers are of classes (A) or (B). The engineer often finds it a commercial impossibility to have the towers built as he would like to design them. The situation is similar to that of the highway bridges 30 or 40 years ago. The bridges of that day would not be tolerated now. The towers of to-day will not be tolerated a generation or two hence.

Tests.—Specifications often require that towers withstand certain artificial tests. This means the minimum amount of material that will meet these tests will be used regardless of other considerations. The conclusions from artificial tests are often misleading. The material is new and in good order, and there is the friction of pieces bolted or riveted close together. The workmanship for the test pieces has at least not been slighted. The structure is assembled at the shop under more favorable conditions than will exist in the field. The loads are applied gradually and in one direction, quite different from those that will come after erection. The test generally takes but an hour or two, while the structure is built to last for years, during which it is subject to a continued test.

What is wanted in steel work is durability. This cannot be assured by a structure simply meeting an artificial test. It may be noted that almost every bridge that has failed or had to be replaced was "tested" before acceptance. This does not mean that a mechanical test has no value. The contention is that an artificial test alone does not give the true value.

For poles which are composed of few pieces and are of simple construction, a greater value may be placed upon the test than for towers which are made up of a multitude of pieces and are complicated in their structure, but for both poles and towers conditions should be imposed regarding thickness of material, relation of unsupported length of column to radius of gyration, and details—the last being considered especially important.

Special Cases.—A careful study should be made of special cases of loading. Generally when a pole or tower fails it is under conditions for which it was not designed. Horizontal and vertical angles in the line should be considered. Some English specifications allow the standard tower to be used without further calculation when a horizontal angle in the line does not exceed 8 deg. American specifications often allow this angle to be 10 deg., though there is no uniformity of practice in this respect. Frequently standard towers are used and the approach spans are decreased. In one large system, where the average cable span length on tangents for level country is 550 ft., the approach spans to angles in the centre line vary from 400 ft. on angles up to 8 deg. to 100 ft. on angles of 45 deg., the maximum angle turned on one tower. Sometimes a standard tower is used and guyed. This is generally objectionable. The most satisfactory practice is to use a tower calculated to withstand the increased loads due to the deviation in the direction of the line. Poles or towers adjoining railroads should be designed to meet special requirements. The specifications issued by some railroad companies for lines crossing their right-of-way are quite severe. The National Electric Light Association's "Specifications for Overhead Crossing of Electric Light and Power Lines" are less stringent. Poles used about manufacturing plants will be mentioned later.

"Flexible" Towers.—What are known as "flexible" towers originated in Italy a few years ago, and are being used to some extent in this country. Semenza, an Italian engineer, conceived the idea of caring for the longitudinal forces in a line through a flexible system rather than by a single rigid tower. By this method an occasional tower, about one in ten, is "dead-ended" or made perfectly rigid to take longitudinal stresses, the intervening towers being made to withstand only the dead weigth and transverse wind loads. If a wire breaks there is a drop in the catenary and the shock is absorbed into the series of poles by each yielding at the top. The "dead-end" tower being designed for all the wires breaking, prevents the longitudinal pull extending farther along the line. The intermediate or standard towers are generally made A-shape of two channels latticed together with angles. The advocates of this method are enthusiastic over the saving they claim in steel material and foundations.

A point generally overlooked in making a comparison between the flexible and the rigid towers is that if flexible towers are used either heavier wire or higher towers are required. With the rigid type, if a wire breaks, the tower at each end will take up the unbalanced loading. In the flexible type, say with three line conductors and a ground wire, if a wire breaks the tops of the towers on either side of the break will be pulled over by the four cables in the next span until the total tension in them would be just balanced by that in the remaining conductors of the damaged span. That is, the three cables remaining would do the work of the four in the adjoining spans, showing the need of heavier wire. Of course, this unbalanced loading can be taken up by a greater sag and less tension in the cables, but this necessitates higher towers to maintain the required clearance underneath the wire. It is an open question just how far flexible towers are to be commended. Does the reduced cost overbalance the lessened reliability? For low voltages with towers or poles comparatively short distances apart, they may sometimes be used to advantage. Where high voltages are used with but eight or ten towers to the mile, rigid towers should be used. The city of Winnipeg in its municipal line from Pointe du Bois on the Winnipeg River to the city, a distance of 72 miles, compromises on the choice of towers. Rigid towers are spaced 1,200 ft. apart with a flexible tower midway between. Towers are 43 ft. to the crossarm and carry a double circuit or six wires.

Foundations.—It matters little how near perfect the superstructure may be, if it rests on insufficient foundation. It will then fail in the hour of stress. The theoretical considerations governing the design of foundations are well known, but it is folly to design these foundations in an office, unless it is known the assumptions made fit the actual conditions of the soil at the site. The attempt to do this will probably result in a footing with an undue margin of stability, causing unnecessary expense, or a footing of insufficient strength, liable to cause trouble ever after. Especially to be condemned is a prevalent practice of placing the steel anchorage without any thought of surrounding conditions. Some towers recently built showed excellent results when tested at the shop in the usual way by firmly fastening the foot of each leg to a heavy steel frame. In the field they were pulled over without any difficulty. The soil yielded and the steel anchorages pulled out. Such designing, or lack of designing, is foolish.

The usual method of anchoring is to run an angle stub 5 to 8 ft. in the ground. This stub extends a foot or so above the ground level, and at the top are open holes for bolts to take the corner legs of the tower. At the bottom of the stub is a cross piece 3 or four ft. long of either channels or angles. This anchorage is placed in a hole dug in the ground and the hole refilled. For light lines with short spans and good soil, this may be sufficient for a time. For the usual long-span transmission line, the overturning moment due to the side wind pressure becomes much larger. A platform at the bottom of the angle stub can easily be designed to withstand the uplift, if the soil conditions are known.

Without any protection save a coat of galvanizing, corrosion is bound to set in at or near the ground level. The writer, a year ago, saw some towers in a cultivated field against the corner angles of which the soil had been turned in plowing. The galvanizing had nearly disappeared, though the towers had been erected but two years. There is trouble at no distant future for those towers. The anchorage should extend not less than a foot above the ground line and should be entirely encased in concrete; though a sleeve of concrete extending from the top to two or three feet below the ground line is sometimes used. Here at once a practical objection is raised. To get water and material at the site of the various towers of a transmission line, make concrete and properly set it, is difficult and expensive. Unless a strict supervision is exercised the work is sure to be slighted.

Thicker steel sections used for the anchorage will delay, but not prevent, failure from corrosion. It has been suggested that the anchor stubs be designed in two lengths, the upper length to be removable and thus replaced without tearing down the tower. A large line installed last year used a preservative paint instead of galvanizing their anchorages.

Life.—The life of a wooden pole is given, if of cedar, as from 15 to 20 years, and longer if preservatives are used. The life of a steel pole or tower cannot yet be definitely stated. It is only as far back as 1903 that the first high-tension transmission line was built in which steel towers were used exclusively. This was a line 101 miles long in Mexico, with towers about 450 ft. apart. The present practice of a multiplicity of light sections will not be conducive to long life. Sections ⅛ in. thick are very common—more of this thickness than of any other are used in the average tower. Towers made of such material, galvanized at the shop, bolted together in the field, and then left alone cannot last for a long term of years.

The use of unusually thin metal for compression values calculated in accordance with accepted formulas is to be criticized. In a number of tower tests, under the writer's observation, the failure was always in the 4 x 4 x ¼-in. corner-angle leg. They were not good for their calculated value. This confirms Talbot & Moore in "An Investigation of Built-up Columns Under Load"[*] in which they write:

> It would seem quite probable that, for columns of the same length and containing the same amount of metal, one which is of stocky form and in which the metal is distributed so as to resist local flexural and torsional action will be much stronger and more satisfactory than a column of more flimsy form, which has its metal spread in thinner sections, even though the slenderness ratio l/r of the former may be considerably more than that of the latter.

Important changes will take place in the direction of thicker material after some of the present lines fail, and the present policy of purchasing only what will answer for the immediate present is abandoned. There is no reason why a tower properly designed, inspected at regular intervals, painted when necessary, should not last 50 years, perhaps longer.

Examples of Towers.

Connecticut River Power Co.—The 917 towers for the line of the Connecticut River Power Co. were designed and built by the American Bridge Co. Of these towers, 862 are the standard, shown in Fig. 1. The specifications, drawn up by J. G. White & Co., call for the strength of these towers to be as follows:

> The towers shall be designed for, and shall be guaranteed to stand, the following test loads without stressing any member beyond its elastic limit:
>
> Insulator pins and grounded wire cap:
>
> (1) At top of insulators for line conductors, 1,600 lb. in any direction perpendicular to pin axis. (2) At top of iron cap support for grounded wire, 1,400 lb. in any direction perpendicular to axis of support.
>
> Supports for pins and cap.
>
> (3) 1,400 lb. load in any direction on grounded wire cap and 1,600-lb. loads in any direction on line conductor insulators to be applied singly or in any combination to produce maximum stress in the supports.
>
> Main tower structure:
>
> (4) A load of 4,800 lb. in any direction at point A (Fig. 1), and no load at B and C.
>
> (5) A load of 4,800 lb. in any direction at points A and B, together with a load of 1,400 lb. in any direction at point C.
>
> In proportioning material the unit stresses were taken at 24,000 lb. per sq. in. net for tension and for compression.
>
> $$\frac{24,000}{1 + \frac{l^2}{13,500\, r^2}}$$

Georgia Power Co.—Some towers designed and built by the American Bridge Co. for the Georgia Power Co. are shown in Fig. 2. Suspension insulators are used. There are 735 towers of the dimensions shown in cut carrying six line conductors of No. 0000 copper wire, and two 7/16-in. galvanized-steel-strand ground wires. The data drawn up for the Georgia Power Co. by the Northern Contracting Co., C. O. Lenz, chief engineer, from which the towers are designed follow:

> The test load shall be: (1) A longitudinal pull of 4,300 lb. at right angles to the end of any one cross-arm. (2) A vertical load of 1,500 lb. at the ends of any or all cross-arms. (3) A load of 1,500 lb. pulling in any direction at the top of tower. (4) A load of 10,000 lb. pulling at right angles to the line or parallel to the cross-arms, that is, 2,500 lb. at each cross-arm. At the same time a pull parallel to the line or at right angles to the cross-arms of 8,000 lb., that is, 4,000 lb. in the same or opposite directions at each end of any single cross-arm or at one end of any two cross-arms.
>
> Cross-arms are proportioned for combined loading (see section on "Loads" under "Towers" above) of Case 1, Case 2, and 1,250 lb. horizontal thrust at end of arm. The tower is proportioned for maximum combination of Cases (2) and (3), or (2) and (4). Unit stresses used are 25,000 lb. per sq. in. net for tension and for compression.

---

[*] Bulletin No. 44. University of Illinois Engineering Experiment Station.

$$\frac{25{,}000}{1 + \dfrac{l^2}{18{,}000\ r^2}}$$

There are also 816 standard towers carrying six line conductors of No. 00 copper wire and two ⅜-in. galvanized-steel-strand ground wires, the towers being 16 ft. square at the base and 70 ft. to the upper cross-arm. The loads for which they are designed are: (1) A longitudinal pull of 3,000 lb. at right angles to the end of any one cross-arm. (2) A vertical load of 1,200 lb. at the ends of any or all cross-arms. (3) A load of 1,200 lb. pulling in any direction at the top of the tower. (4) A load of 8,000 lb. pulling at right angles to the line or parallel to the cross-arms, that is, 2,000 lb. at each cross-arm. At the same time a pull parallel to the line or at right angles to the cross-arms of 5,000 lb., that is, 2,500 lb. in the same or opposite directions at each end of any single cross-arm or at one end of any two cross-arms.

The combination of loadings and unit stresses is the same as for the towers with No. 0000 wires.

In addition to the above standard towers there are 200 towers designed to meet special conditions.

Structural-Steel Poles.

It has been requested that structural-steel poles be given a prominent place in this paper. Much of what has been written is intended to be applicable to either poles or towers, though for transmission and distribution systems about the yards of manufacturing plants some of the conditions are quite different from lines through great stretches of open country. The size of base is restricted to as small an area as possible. This necessitates a pole instead of a tower.

The loads to be carried and the desired permanency demand a steel instead of a wooden pole. An interruption of service, even for a short time, means inconvenience and loss. Accidents to life and property, if any occur, are liable to be disastrous and must be guarded against. The seriousness of failure on such lines will justify heavy construction. For this reason it is recommended that each pole be designed to withstand, in addition to the dead and wind loads, the unbalanced load due to a majority of the wires coming upon it being broken. All conditions such as the probability of wires being added in the future, the deviation of the line from a tangent, or special loadings, should be considered. A unit stress of not more than 16,000 lb. per sq. in. net for tension and the same reduced by previous formula for compression should be used.

The foundations shall be of concrete and shall be designed in accordance with local conditions. These local conditions should be thoroughly understood. A clause from the specifications of New York Central & Hudson River R.R. for lines crossing railroads is applicable here:

> The foundations shall be of concrete ond shall be designed so as to be able to resist the greatest tendency to overturn due to any combination of the loads specified. No steel shall be carried below the surface of the ground unless encased in concrete. The tops of foundations or tops of the concrete casing shall not be less than 12 in. above the ground and always above flood water.

Indiana Steel Co.—The latest word in the various departments of steel manufacturing may be found at Gary, Ind., in the plant of the Indiana Steel Co. Attention is called to a paper in the Transactions of the American Institute of Electrical Engineers for 1909 entitled, "The Industrial Application of the Electric Motor, as Illustrated in the Gary Plant of the Indiana Steel Company," by R. R. Shover It is valuable on account of the detail with which the writer has gone into so many phases of his subject.

The standard 40-ft. two-arm pole is shown in Fig. 3. The poles and towers throughout are designed to carry the dead load of the construction, including a coating of ice on the wires equal in thickness to the radius of the wire, together with an overturning load of 20 lb. per sq. ft. on the towers, and 10 lb. per sq. ft. on the projected area of the wires; also a torsional stress in any pole produced by an unbalanced load resulting from the cutting of 25% of the wires in the adjacent span. The unit stresses used are those of the American Railway Engineering and Maintenance of Way Association. No material less than 5/16 in. thick is used.

Westinghouse, Church, Kerr & Co.—R. A. Marshall, structural engineer, has designed and built a number of poles for the yards of railroad shops. Fig. 4 shows a typical pole and its foundation.

Each pole is carefully worked out by itself. The dead loads are the structural steel and the wires with a covering of ice ¼ in. thick. The wind load is figured at 13½ lb. per sq. ft. on projected diameter of wire with ¼-in. ice coating. The tension in wire is figured on a basis of 100 ft. span with 3% sag at centre. A number of these poles take pulls at right angles to the main line which adds materially to the stresses. This is not an uncommon feature in the yards of railroad shops and manufacturing plants.

The steel is designed for two-thirds of the computed loadings with a unit stress of 16,000 lb. per sq. in. net in tension and 16,000 lb. reduced by the formula for compression. No material less than ¼ in. thick is used. Observe that the foundation is of ample proportions.

Pennsylvania R.R.—Among the interesting features of the New York tunnel extension of the Pennsylvania R.R. are the poles through the Meadows section in New Jersey. There are two lines, one for telegraph and telephone purposes, and one for power transmission; they were designed by R. D. Coombs. The poles of the telegraph lines are of concrete, 25 to 50 ft. high and spaced 70 to 135 ft. apart. The poles of the high-tension transmission line are of latticed steel, parabolic outline, square in cross-section, with one angle at each corner and single angle bracing. They are designed not only for present requirements but a liberal provision is made for future needs. The Hackensack River is crossed midway in the Meadows section. The adjoining poles, at the time they were built, were the highest in this country.

These poles (or tower-poles) are 765 ft. apart. Each one is 15 ft. square at the base and 3 ft. square at the top. The tops of foundations are 6 ft. above high water, and from the top of the foundation to the ground line is 188 ft. 4 in. Special features are: Large number of heavy wires, of voltage requiring some separation, carried at a minimum clear height above high water of 133 ft. No strain insulators were available of sufficient electrical or mechanical strength, therefore nests of pin insulators carrying saddles were used to support the wires on the poles. The poles present a graceful appearance. The base is small in area—a greater spread would further obstruct the river and increase cost of foundation. On account of the importance of the line in operating the terminal division of a great trunk-line railroad, conservative data were used for calculations. These data are as follows:

Wires—

River Span: One 250,000-circ. mils, hard-drawn stranded copper ground wire; twenty-four 250,000-circ. mils, hard-drawn stranded copper line wires; four 250,000 circ. mils, hard-drawn stranded copper signal wires; two 2,000,000-circ. mils, hard-drawn stranded copper feeder wires.

Adjoining span same as river span.

Second adjoining span, same as river span except for signal wires—four No. 00 hard-drawn solid copper.

Loading—

One-half-inch ice on all wires with 8 lb. per sq. ft. wind pressure on diameter multiplied by length.

Thirteen pounds per square foot of wind on 1½ times the pole area.

Normal sag 31.8 ft.

Transverse pull 24,900 lb.

Longitudinal pull 22,135 lb.

Unit stresses: Steel in net tension 15,500 lb. per sq. in.; steel in compression 17,600 lb. per sq. in. reduced by formula.

New York Central.—The poles near New York City for the electric-transmission lines of the New York Central & Hudson River R.R. are often quoted as good practice. Fig. 5 shows the standard pole carrying 12 high-tension conductors.

It is made of four corner 3½ x 3½ x ⅜-in. angles laced with 2½ x 2 x ¼-in. angles. Poles on a tangent are 150 ft. apart with a wire sag of 30 in., those on a 6 deg. curve are 107 ft. apart with wire sag of 15 in. The dead loads are the structure itself with the wires covered with ½-in. coating of ice. Wind pressure is taken at 30 lb. per sq. ft. on the surface of the pole and on all wires covered with ½-in. coating of ice. The unit stresses used are 30,000 lb. per sq. in. net for tension and for compression

$$\frac{30{,}000}{1 + \dfrac{l^2}{125\, r^2}}.$$

While these unit stresses seem high, the loadings are large. The foundation is a solid block of concrete. The cross-arms are of wood, probably to secure greater insulation.

Long Island R.R.—A similar substantial sonstruction is used by the Long Island R.R. for their steel poles on Long Island. The parabolic outline is abandoned. For the high-tension wires the wind is figured on the bare wire; for the low-tension wires it is figured on the wire covered with sleet ½ in. thick. Wind pressure is figured according to results of German high-speed railway tests, where pressure per square foot = $0.0027\ V^2$. With a velocity (V) of 100 miles per hour, wind pressure = 27 lb. per sq. ft. on flat surfaces and 13½ lb. per sq. ft. on projected areas of conductors. Side pull on pole is figured for a centre deflection of 6 ft. with poles on 150-ft. centres.

N. Y., N. H. & H. R.R.—The 40-ft. yard poles of the New York, New Haven & Hartford R.R. used in the electrification of the Harlem River Branch, are rectangular in cross-section of four 5 x 3½ x ⅜-in. angles, double latticed on all four sides with 2¼ x ⅜ and 2¼ x ½ in. flat bars. The poles, back to back of angles, are 2 x 3 ft. at base and 2 ft. by 2 ft. 2 in. at top. The base of each pole is made specially strong From this base, four anchor rods of 1¾ to 2⅝ in. diameter and upset at ends run down 8 to 10 ft. in a concrete foundation.

J. G. White & Co.—Some poles designed by S. R. Jones, structural engineer of J. G. White & Co., are simple in construction. They are for a transmission system in the Middle West and are shown in Fig. 6.

The data upon which design is based is:

Power wires: One circuit No. 1 stranded medium hard-drawn copper; one circuit No. 4 stranded medium hard-drawn copper.

Ground wire: No. 8 copper-clad steel.

Maximum allowable tension in wires: Fifty per cent. of breaking strength with ½-in. coating of ice and wind load of 8 lb. per sq. ft. on horizontal projection of increased diameter of wire.

Assumed loads on pole: Vertical loads: Crossarm = 600 lb. at end of crossarm; pole = weight of pole + weight of wires covered with ½-in. thickness of ice.

Horizontal loads: Total pull of 2,500 lb. applied at middle crossarm in direction of line, or at right angles to line plus wind load on pole at 20 lb. per sq. ft. on exposed surface (both sides of pole included in surface exposed to wind pressure).

Unit stresses in steel: 24,000 lb. per sq. in. net for tension; 24,000 lb. per sq. in. reduced by formula for compression.

The preceding poles may be taken as illustrating the best practice of to-day. It will be seen that they have much in common. In each case the pole is made of four angles latticed.

Various Poles.—A pole made of two channels laced has been used, but such a pole is limited to light loads and low heights. The same can be said of a pole made of one plate and four angles. Foster ("Electrical Engineer's Pocket-Book") gives the deflection of some poles 6 ft. in ground and 24 ft. above ground, made of 6-in. to 12-in. by 3/16-in. plate and four 2½ x 2 x ¼-in. angles, for loads of 500 to 2,500 lb. applied 3 ft. from the top, to be from 1 to 5 in. These poles were used for electric railway service. The plate-and-angle pole has the advantage of being a good shape for inspection and painting.

Patented poles, made of rolled-steel sections fastened together at intervals, are on the market, and are meeting with considerable sale. They show good results for vertical loads, but the sections being battened and not laced together are adapted to carry only light lateral loads to the base. It is the custom to guy these poles from the top if the lateral forces are large. This restricts their use.

Conclusion.—The use of steel poles and towers is on the increase. This paper is not intended to be a complete discussion for the field is too varied and too large to be thoroughly reviewed in a single paper. It is hoped, however, what has been written may not be without interest, and lead to further discussion on the subject.

THE DIESEL ENGINE FROM THE USER'S STANDPOINT.

The Diesel engine is coming into such general use for the purpose of the generation of electrical energy that a few notes on its advantages, cost of running, and maintenance, may be of interest. Mr. Wm. J. U. Sowter read a paper recently before the Dublin local section of the Institution of Electrical Engineers. A few abstracts of the paper which are of particular interest follow:—

Although several papers have been written on the subject, most of the conclusions arrived at are based on estimated results, and it is, therefore, the intention of the author to discuss the matter from the user's standpoint, quoting as far as possible results obtained in actual practice.

The following is a specification of a suitable oil which the author has adopted with satisfactory results:—

1. The oil shall be either crude, refined, or a residue of petroleum.

2. It shall be free from tar, bitumen, or solid hydro-carbons; it shall be also be free from sand, fibrous matter, or foreign solid impurities.

3. The oil shall not contain more than one-half of 1 per cent. of water, nor 1½ per cent. of sulphur, and shall be free from acid.

4. The viscosity shall be such that the oil will flow in a continuous stream with 1 ft. head through a ½-in. copper pipe 6 feet long without pre-heating.

5. The calorific values shall not be less than 18,000 B.t.u. per lb.

Many other liquid fuels may be used, such as residue shale oil, gasworks tar oil, or creosote oil

Running Costs.—Contrasted with steam plant, there is but little difference in fuel consumption per B.H.P.-hour between large and small Diesel engines, nor does the fuel consumption increase largely per unit of energy as the load is decreased on the engine. It is well known that a large steam engine running at light load is grossly inefficient, the fuel required to maintain steam pressure in the boilers and to run the engine light, together with the necessary auxiliaries, being out of all proportion to the work done; also, a small steam engine requires many more pounds of steam per h.p. to run it fully loaded than does a large one. In addition to these considerations there is the serious question of stand-by losses, which are very great indeed with steam plants, while they are absolutely non-existent where the Diesel engine is used.

It is apparent from the foregoing remarks that it is unnecessary from the point of view of fuel economy to install large engines when a greater number of small engines will suit the circumstances of any particular case better, desirable as the former procedure may be so far as capital cost per kilowatt of plant installed is concerned.

The following figures show the cost of fuel per unit generated with oil at the prices mentioned, and at various loads, for a 50-B.H.P. engine coupled to a 33-k.w. generator:

Load.	Dynamo Efficiency.	Price of Fuel per Ton.			
	Per Cent.	40s.	50s.	60s.	70s.
Full	88	0.161	0.201	0.242	0.281
Three-quarter	86	0.178	0.210	0.252	0.295
Half	83	0.208	0.261	0.314	0.365
Quarter	78	0.307	0.384	0.462	0.538

These figures are not merely manufacturer's "paper" figures, and the author is in a position to vouch for them personally, he having obtained similar results after repeated tests at irregular intervals. On larger plants the cost would be some 10 to 20 per cent. better, depending upon the size of the plant.

Figures such as the above clearly demonstrate the great advantages this type of plant offers for use in small generating stations.

Capital Cost.—The capital cost of a Diesel engine direct-coupled to a generator is considerably greater than a gas or steam-driven generator of similar capacity, but when the costs of complete plants, comprising either gas or steam, are compared, there is but little differences in the price per kilowatt. A Diesel station, however requires less land and building than similar stations employing steam or gas plant, so that the difference, if any, is in favor of the Diesel plant.

The following are approximate prices for small plants, delivered and erected on purchaser's foundations complete with all oil storage tanks, piping, etc., and may be taken as fairly representative:—

Size in Kilowatt.	Price.	Price per Kilowatt.	F.O.B. Works.	Weights.
100	1,950	19.5	1,340	19,450 lbs.
150	2,600	17.3	1,770	23,250 lbs.
200	3,260	16.3		
300	4,380	14.6		
400	5,300	13.3		

FILING SHOP DRAWINGS AND RECORDING PROGRESS OF WORK.

A very simple method of filing shop drawings and recording the progress of shop work has been adopted in the superintendent's office of the Dominion Bridge Company, at Lachine, Que., and is described in a recent issue of the Engineering Record. The drawings of all work in progress, amounting to fifty or more jobs, are uniformly filed in a very convenient and accessible manner and the main features are daily posted on to them in such a way that the condition of the work can be instantly determined by inspection. Each complete set of shop blueprints of standard size is clamped between two 2 x ¼-in. hardwood strips, 24 in. long, that are fastened across one end of the sheets. Attached to the centre of one of the strips is a U-shaped clamp of 2 x ⅛-in. iron with one leg about ¾ in. clear of the fixed strip. The ends of the drawings are placed between the fixed and loose strips, the latter being set inside the clamp and forced down to bearing by driving a thin steel wedge under the projecting leg of the clamp between it and the loose strip. This holds the blueprints tightly in position at the centre of the strip and prevents their slipping, while the edges of the sheets at the ends of the strips, although not held closely by the latter, cannot be displaced on account of the centre clamp and are protected by the wood strips which shield without clamping them.

The fixed strip has a frame for a title card close to the clamp and the clamp is provided with an eye by which it is suspended from the horizontal leg of a long hook having a vertical shank clamped between a small angle and a flat bar about 15 ft. long which are supported at the ends and intermediately. The hooks are set 3 or 4 in. apart at a height of about 5 ft. above the floor and provide for the very convenient and accessible filing of the drawing which can be selected or restored to the file independently.

Every day the number of pieces finished and inspected are checked off by red and yellow marks, respectively, on the blueprint, or as soon as any set of pieces is completed it is indicated by a circular check mark of the proper color. When all of the pieces on a sheet are finished large circles are drawn on the title to indicate it. The drawings are examined daily and when a job nears completion if scattering pieces are incomplete they are entered up in a "short-order" book which is posted daily and quickly shows any deficiency that may be made in shipment on an order.

OTTAWA LIGHT COMPANY'S CAPITAL INCREASE SANCTIONED.

The Dominion Government has sanctioned the proposed increase in the capital stock of the Ottawa Light, Heat and Power Company, Limited, from $2,000,000 to $5,000,000. This increase will be made by the issue of 30,000 new shares of $100 each. Of the present authorized capital of $2,000,000, at the end of 1911 $1,984,400 was subscribed and paid. This was an increase in paid-up capital of $404,000 over 1910. It represented 14,910 shares of the Ottawa Electric Company and 4,934 shares of the Ottawa Gas Company, which were exchanged at par for shares of the Ottawa Light, Heat and Power Company.

The Ottawa Light, Heat and Power Company this week declared a bonus of 1 per cent. with the usual quarterly distribution of 1¾ per cent. on the stock of the company. A similar bonus was paid last year with the dividend at the same rate as this year; a stock bonus of 25 per cent. was also paid in 1911. In 1910 the dividend rate was 6 per cent. with which a 2 per cent. bonus was paid, and in 1909 5 per cent. with a bonus of 1 per cent.

YORK COUNTY GOOD ROADS.

A significant result of the improvement which has already been done on the roads throughout York County which lead into the city of Toronto is the falling off in the use of the elevators. This past fall the elevators within a radius of twenty miles and outside the city limits have only done about one-third of the regular business.

This has been due to the fact that the farmers are now able to draw their grain directly into the city, thereby securing better prices and increasing the business of the city elevators.

Good roads mean not only better prices for the farmer, but lower cost to the consumer. Increased facilities in marketing produce by the bettering and improvement of the highways always result in the forming of new business and the development of added sources of trade.

York County good roads have been vastly improved by the money already spent on them, but there is still much to be done. The by-law now before the ratepayers for the additional amount of $100,000 deserves the hearty support of the city.

◆

TORONTO'S WATER BY-LAW.

Are the citizens of Toronto satisfied that the by-law now being placed before them, to provide six million dollars for a duplicate water supply from Scarboro Heights will give them the best and most economical location for the future water supply of the city?

It is interesting to note the reasons on which the Water Commissioners based their choice of Scarboro Heights. The proposed location of the intake crib off Scarboro is twelve miles from the present intake, while the effluent from the Morley Avenue sewage disposal works, which will ultimately handle practically all of the city's sewerage, is discharged about half-way between.

The Commissioners are agreed in their report that Lake Ontario must remain the future source of supply. They state that from the evidence to hand the transporting lake currents are from the east to the west, and that there is a lesser probability of impure water to be met with off Scarboro than off Mimico. They add that there is no location within ten miles of the north shore lake from which water can be drawn which will at all times present a safe supply, unless such water be subject to some form of purification.

On page 6 of the report the following are given as the reasons for the choice of Scarboro:—

"That all the available evidence points to the necessity of increasing the water supply to meet the demands of one million population, and that it is not advisable to rely upon the present location for such increased supply. Taking into consideration the probable future growth of the city, it is reasonable that the present location of supply be considered only as a central unit, and that extra units be installed either east or west of the central unit.

"That, owing to the demonstrated fact that pure water is obtainable for longer intervals of time east of the harbor than to the west, and, owing to the high elevation of the plateau at Scarboro, a second unit be first installed at this location.

"That until Toronto can be assured of a second independent and reliable supply of water from the lake, what have been considered as exceptionable and unpreventable circumstances may again arise, to the discomfort of the citizens and consequent lack of confidence in the organization of the Water Works Department of the city."

Evidently, then, their decision is based on these facts:—

1. That the past troubles with the present location of the intake debar Centre Island as the main source of supply.

2. That the increase in the city's population demands units east and west of the present plant.

3. That there is greater probability of obtaining pure water for greater length of time at Scarboro.

4. That there is high ground at Scarboro for the location of a reservoir to provide gravity supply.

The Scarboro project provides for an intake tunnel ten feet in diameter and two miles long; pumping machinery of sixty million gallons capacity; a mechanical filtration system; covered reservoir, and gravity mains from the reservoir throughout the city. The total estimated cost is given as $5,320,000. As a matter of fact, we believe that this amount will be considerably exceeded if the plant is constructed, as the amount estimated for many of the items is too low.

The past troubles with the intake of the present plant on Centre Island have been due to faulty design and construction. The Commission proposes at Scarboro to spend $1,346,600 for intake purposes alone. It will cost to do this work at least a million and a half. If this same amount of money, or even half of it, were spent in installing an intake crip with intake tunnel at Centre Island, an independent and duplicate supply could be secured at that point.

That the increase in the city's population demands units east and west of the present plant sounds like a reasonable argument by the Commissioners, but we note in their report that they expect to supply West Toronto with water from Scarboro, a distance of fifteen miles. If the reason for the choice of Scarboro is the extension of the city's area and population eastwards, then why do the Commissioners contemplate the supply of West Toronto from Scarboro? Why not use the Centre Island plant, which is much nearer? With the city's population increased to one million, it is very doubtful whether the eastern and western limits of the city will be extended beyond what they are to-day. The central system to-day has no difficulty in supplying all parts of the city.

There is a greater probability of obtaining purer water for greater lengths of time east of the sewage disposal works at the Scarboro location. There is little difference, however, in the quality of the water at Centre Island and at Scarboro, and in any case, as the Commissioners note, continuous filtration is absolutely necessary.

Coming to the last point in the choice of Scarboro is the fact that there is high ground for the location of a reservoir. The distance from the Scarboro reservoir to the present High Level Pumping Station is a matter of twelve miles. To deliver the ordinary output of the Scarboro pumping station of sixty million gallons a day there will be a loss of about forty-five feet of head. At times of peak load this loss through friction will increase to one hundred and fifty feet of head. The High Level Pumping Station is at practically the centre of gravity of supply of the city. A comparison of the Centre Island supply with the Scarboro supply delivered at the High Level Pumping Station shows that it will be necessary to pump against a head of from forty to one hundred and fifty feet greater with the Scarboro scheme, and, in order to secure this privilege (if it may be so stated) it will be necessary to spend over $6,000,000.

A city of such size and growing importance as Toronto demands an absolutely continuous supply of pure water, and it is therefore quite necessary that there should be provided in the near future a duplicate supply of the present one. In reading over the Commissioners' report we have wondered whether they analysed the possibility of obtaining that duplicate supply from Centre Island. At an expenditure of not over $3,000,000 an intake crib and intake tunnel similar to that outlined for Scarboro, a filtration system, and a second tunnel under the bay could be built. This would furnish an absolutely independent supply of water to the city at the logical point for supply, the centre of population of the city. The water would be furnished to the consumer as it is at present, under a minimum amount of pumping.

If Scarboro were located, say, fifty miles east of Toronto on the lake front, the absurdity of choosing such a location simply because a high plateau existed there would be quite apparent, unless the quality of the water was so very much better as to justify the increased cost. Because a high plateau exists some twelve miles east of the city, which affords an excellent location for a reservoir, it does not follow that it will be economical to pump the water up to this plateau and then let it gravitate to the city. It must be remembered that the advantages of a gravity supply are sadly minimized when it is necessary to elevate the water to the upper level by pumping, and then lose this extra head by friction loss in the many miles of pipe necessary to convey the water to the city.

The facts against the Scarboro location are this—the quality of the water is very little better than that at Centre Island, and must be continuously filtered. There will be a continuous future loss of head due to the flow of the water through twelve miles of pipe in order to reach the centre of population of the city. It will cost at least $4,000,000 more to install a plant there than to build a duplicate plat at Centre Island; that is, greater first cost of construction, greater continuous cost of operation, no better water after filtration, are the arguments against the Scarboro scheme.

The citizens of Toronto are not justified in proceeding with the construction of a Scarboro plant on the evidence submitted in the report of the Commissioners.

EDITORIAL COMMENT.

The annual meeting of the Canadian Society of Civil Engineers will be held on the 28th, 29th, and 30th of January next. It is expected that the Society's new building at 176 Mansfield Street, Montreal, will be finished by that date, and the meeting will therefore be held there. All members should make an earnest effort to be present.

GENERAL NOTES.

Precipitation was decidedly deficient in the Western Provinces and in New Ontario and in excess of the average over a portion of Ontario lying between Lake Huron and the Ottawa Valley and also throughout the Province of Quebec, elsewhere departures from average were not pronounced. Snow occurred in all the provinces.

At the close of the month, snow to a greater or lesser depth, was on the ground in many parts of Canada. In northern districts of the West the depth was over 10 inches, this being also the depth in the Ottawa Valley and the Gaspé Peninsula. In southern districts of the Western Provinces, the ground was nearly bare of snow, a trace being reported from most localities. Nova Scotia and Prince Edward Island were snow covered to a depth of 3 to 7 inches.

The table shows for fifteen stations, included in the report of the Meteorological Office, Toronto, the total precipitation of these stations for November, 1912:

	Depth in inches.	Departure from the average of twenty years
Calgary, Alta.	0.5	—0.22
Edmonton, Alta.	0.4	—0.44
Swift Current, Sask.	0.4	—0.25
Winnipeg, Man.	0.1	—0.98
Port Stanley, Ont.	2.3	—0.71
Toronto, Ont.	2.38	—0.15
Parry Sound, Ont.	4.5	+0.50
Ottawa, Ont.	6.7	+4.35
Kingston, Ont.	3.6	+1.01
Montreal, Que.	6.3	+2.86
Quebec, Que.	4.6	+1.53
Chatham, N.B.	4.6	+0.78
Halifax, N.S.	5.5	—0.38
Victoria, B.C.	5.0	—1.07
Kamloops, B.C.	..	....

LETTERS TO THE EDITOR.

LIGHT COMPRESSION MEMBER.

Sir,—I wish to thank Mr. C. R. Young, through The Canadian Engineer, for his pertinent comments upon my letter of November 23rd.

I can hardly agree, however, with his opinion that the assumption of an unequal distribution of stress across the sectional area of a compression member is poorly founded theoretically. Permit me to call attention to an article entitled "Elastic Equilibrium of Circular Cylinders Under Certain Practical Systems of Load," by L. N. G. Filon, and published in the Philosophical Transactions of the Royal Society of London, Series A, Vol. 198.

Quoting from this article for the benefit of those who may not have the article at hand; speaking of a circular cylinder in direct axial compression, Mr. Filon states: "The axial pressure deviates throughout from uniformity over the cross-section, the total variation in any section remaining tolerably constant over nearly two-thirds of the length of the cylinder." We notice, also, that near the centre of the cylinder the greatest pressures occur at the centre of the cross-section, whereas the reverse takes place at the ends, the pressure at the perimeter of the ends amounting to about 1⅓ times the mean pressure." Further on, speaking of cylinders under the same condition, except that the ends are prevented from expanding, he states: "It is thus not surprising that the greatest pressure should be at the perimeter, being in fact nearly 2½ times the pressure at the centre."

It seems to me that this shows the assumption of a varying distribution of stress is theoretically more reasonable than the uniform distribution. Furthermore, the case cited is for a circular cylinder, and the distribution of stress depends on the shape of the sectional area, so that the case of a "built-up" section may be even much worse than that of the cylinder.

Hence, I must still maintain that my suggestions, although perhaps not convenient for engineering practice, are not at all impossible theoretically.

The important point brought out by Mr. Young, that the position of the points of application of the load and the way in which the load is applied is an important factor in determining the distribution of stress over the sectional area, is certainly very important in specific cases where the method of loading is known, but a general theory of "built-up" compression members could not be made to take all possible cases into account.

Perhaps the most sensible way to apply the idea of an unequal distribution would be to reduce the allowable stress on the cover-plates of a "built-up" column in some proportion depending on the percentage of area included in the cover-plates.

Thanking you for the attention which you have given me in this matter.

Yours very truly,
I. F. MORRISON.
University of Alberta, Edmonton South, December 12th, 1912.

CANADIAN ENGINEERS AND DRAUGHTSMEN.

Sir,—The remarks of Mr. F. Tissington in your issue of November 14th do not in any way demonstrate further the alleged need of more technical schools to make up for the lack of experienced draughtsmen. Technical classes do not make experienced engineers and draughtsmen. This year 545 engineering students entered at McGill, and yet technical men are being engaged direct from Britain or the States, who cannot be said to be experts in a particular line. There must be a gap somewhere. And that gap is inexperience. The degree of competition in Canada can be judged from the dismal failure to recruit men for the still-born Canadian navy. If a man considers he is not fairly treated in a drawing office, nothing is easier than to get another job. This frequent moving about militates against a draughtsman becoming thoroughly experienced in one branch of engineering. I strongly resent Mr. Tissington's unwarranted insinuation as to the treatment of draughtsmen in Great Britain, and can only suppose that he was extremely unfortunate with his employers there. Office hours in Canada, even in Ontario, are longer than in England, South Africa, or probably any other country in the Empire.

As to draughtsmen in Britain having all had shop experience, I referred particularly to mechanical engineering, and I rigidly adhere to this statement.

Yours faithfully,
C. O. Thomas.
Montreal, December 20th, 1912.

PRODUCTION OF METALS IN ONTARIO.

The total production of metals in Ontario, as given below, is subject to a slight deduction, due to its including not only iron ore but also pig iron, into which some portion of it was doubtless smelted, states Mr. T. W. Gibson, deputy minister of mines, in the twenty-first annual report of the Ontario Bureau of Mines, but, after making allowances of this sort, the aggregate value cannot be less than one hundred and eighty million dollars.

THE YORK COUNTY HIGHWAY COMMISSIONERS' REPORT

As an introduction to the second annual report dealing with the roads under control of the Board of Highway Commissioners, York County, the following facts concerning the early roads of York County may prove of interest.

The first survey of highways in what is now York County was made in 1791, by Augustus Jones, when he sub-divided what are known as the townships of Scarboro and York. In the following year York County was formed, although its area was many times its present size.

In the first Parliament of Upper Canada, which met at Newark (Niagara Falls), in 1793, the roads were placed under overseers who reported to the military authorities of the British Government, who provided the necessary money for construction and improvements.

The Parliament of Upper Canada granted in 1830, $512,000 for road construction throughout the Province, and in the same year the Statue Labor Act came into force.

By this Act every male resident of the Province between the age of 15 and 60 years were required to give two days' labor towards the building and repairing the highways of the Province.

The Act which united the Provinces of Upper and Lower Canada in 1841 also provided for municipal institutions and the road came more directly under the control of local officials.

In 1891 and each succeeding year efforts were made in the County Council of York to abolish the collection of tolls on York roads on condition that the City of Toronto cease to collect market fees other than cattle market fees.

In 1893, City of Toronto took over the Lake Shore Road and the tollgates on this road were abolished in 1896, under By-law 712, J. Slater being Warden. A by-law to abandon the York roads and transfer the same to the minor municipalities of York County was carried in 1896.

YORK HIGHWAY COMMISSION

Lewis Gardhouse, Warden, 1912 D. Sinclair, Tr[illegible] Dept. R. W. Phillips, Secretary. R. J. Bull, Warden 1911 Geo. S. Henry,
W. G. Trethewey, Commissioner. E. A. James, Chief Engineer. W. H. Pugsley, Vice-Chairman. J. J. Ward, Chairman.

In the following year, 1794, Yonge Street was surveyed and partly cleared, but as revenue for road work only amounted to $900.00 per annum, very little permanent construction could be undertaken.

The Don Mills Road was surveyed in 1799 and the following year an overseer was appointed, but it was not until 1821 that permanent improvements of an expensive character were undertaken.

The Danforth Road was commenced in the same year, and about 60 miles of the road was opened.

The Lake Shore Road was cleared in 1804.

The Dundas Street, the highway to the west, although partly opened in [illegible] was not [illegible] until after the War of 1812.

The Northwest Fur Co. offered the Government in 1815, $60,000 to improve Yonge Street, but only a small amount of this money was ever contributed and the road, although used as a military highway, was not put in good condition until 1835.

Following the assuming of the roads by the townships, efforts were made from time to time to again establish a County System, Mr. W. H. Pugsley, at the June session in 1899, moved a resolution which was seconded by Mr. James Ley, "that the Council, resolve itself into Committee of the Whole to consider the advisability of organizing and assuming a system of leading roads as county roads, and also as to petitioning the Provincial Legislature to assist in the maintenance of the same."

With instruction the committee arose and reported the following resolution: "Resolved, that the Clerk be and he is hereby directed to procure all the information possible with reference to a scheme whereby a system of county roads may be maintained by the County and Provincial assistance, for the use of this Council at its November session."

This resolution was received and adopted.

The committee thus appointed, realizing the magnitude and importance of the subject, in order to obtain as much information as possible and also to act in union with other counties of the Province, called a convention of municipal representatives of the Province, on December 12th and 13th of that year, to consider the question. The report of this convention was printed and distributed, and doubtless had much to do in bringing the necessity of improved roads and the advisability of an early start in that direction before the electors of the county.

In January, 1902, the following resolution was carried by the York County Council: "That the By-law and Legislative Committee be and they are hereby directed to prepare and have introduced in the Local House a petition asking that the clauses of the Act under which bonuses are granted to street railways be made to apply to the making of improved roads in townships, with a further provision that when any locality in a township vote to provide two-thirds of the costs of any such improved roads, the townships in which any such locality is situated shall pay the other one-third." No action, however, was taken by the Government.

In order to take advantage of the Act for the Improvement of Public Highways, passed in 1901, whereby the Provincial Government agreed to bear one-third the cost of the construction and improvement of County Highway Systems approved by the Government, the following resolution was passed by the County Council in June, 1903: "That this Council be now resolved into Committee of the Whole to discuss the advisability of taking over and maintaining certain roads in the County as County Roads, and thereby receive a portion of the amount set apart by the Government for making good roads." This Committee afterwards drafted a by-law which was submitted to the various township councils. More than one-third of the township councils disapproved of the by-law, and, under the provisions of the Act covering such cases, it was necessary to put the question to the ratepayers. This was done in January, 1904, the result being a majority against the proposal.

The matter then lay dormant till June, 1906, when Mr. W. H. Pugsley moved that the Council resolve itself into Committee of the Whole at the November session to discuss the advisability of again submitting the question of County Roads to the electors of the County for their approval or otherwise.

This Committee at the November meeting reported the following resolution: "Resolved, that the Council do at this session of the Council report a by-law setting apart certain roads as County Roads, and that the by-law be submitted to the various Township Councils for their approval as provided by the Act of 1901 and amendment thereto." This was defeated.

At the June session, 1907, the by-law to assume certain leading highways as a County Road System was defeated by a vote of 10 to 16.

During the sessions of 1908 the question of County Roads was again considered, but it was not until the December session of 1909 that substantial progress was made towards the present scheme by the passing of a resolution forming South York for County Road purposes and directing the Legislative Committee to meet the Council of the City of Toronto with a view to securing city aid for the improvement of leading highways.

At the June session of 1910, Mr. Geo. Henry moved, and Mr. W. H. Pugsley seconded, that Messrs. Annis, Nigh, Longhouse, Gardhouse, Bull, the mover and the seconder, be a committee empowered to draft a schedule of highways for a County Road System in the part of the county within the riding of East and West York.

This committee secured legislation authorizing the York County Council to adopt a County Road System for the portion of the County included in the Electoral Districts of East and West York and for issuing debentures assessable on that portion of the County, only exempting the municipalities that compose the Electoral District of North York. The Committee drafted a schedule of the leading roads in this section of the County, which roads now comprise the County Road System.

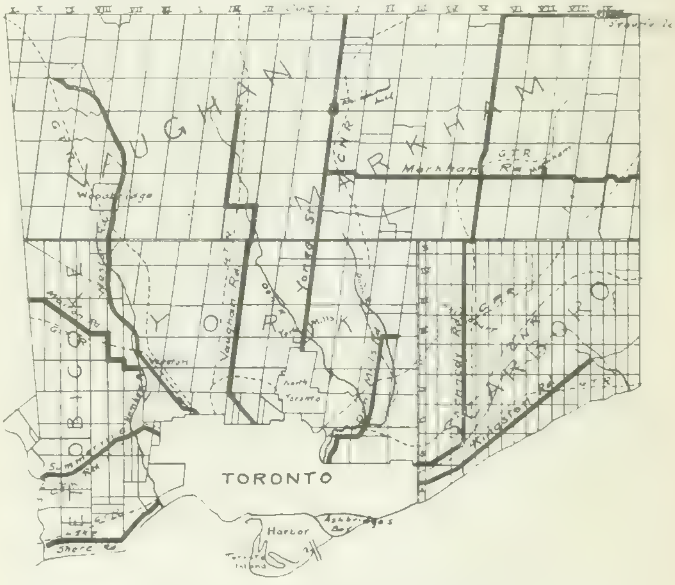
At a joint meeting of the above Committee and representatives of the City Council, Toronto Board of Trade, and the Ontario Motor League, the following resolutions were passed:

"Moved by Reeve Henry, seconded by W. J. Gage, that this joint Committee representing the City of Toronto, the County of York, the Board of Trade, and the Ontario Motor League recommend that the City of Toronto and the County of York each contribute one-third cost of constructing permanent roadways within the County of York, the remaining one-third to be contributed by the Provincial Government under the conditions of the Statutes in relation to the improvement of highways."

"Moved by Reeve Bull, seconded by W. G. Trethewey, that the City of Toronto and County of York strongly recommend the vote of a grant of $100,000 to be set apart for the purpose of improving the highways mentioned in the resolution so that the work can be commenced at the earliest possible date."

"Moved by W. J. Gage, seconded by Reeve Annis, that this joint Committee recommend that the County of York, the City of Toronto and the Provincial Government each appoint a representative who would practically constitute a commission to have charge and supervision of the expenditure of moneys given by the different municipalities and the Government in connection with the improvement of highways."

In January, 1911, a by-law was submitted to the electors of the City of Toronto to raise the $100,000 recommended as the city's share of the project, which by-law was carried by a substantial majority.



Good Roads Scheme, York County.

Showing Roads Under the York Highway Commission.

Early in 1911 the County Council passed by-laws: to designate the roads to be improved; to raise $100,000 as the County's share by the issuing of debentures; to confirm the agreement with the City of Toronto whereby the city and the county were each to bear one-third of the expense of construction, the remaining one-third to be borne by the Government; to relieve the municipalities lying in North York from liability for the cost of the new roads; and to appoint Commissioners to act with others appointed by the city and the Government.

According to the agreement with the city, the Board of Highway Commissioners was to consist of three persons appointed by the County, two by the City and one or more by the Government. The original personnel of the Board was as follows:

For the County—Messrs. R. J. Bull, Wm. H. Pugsley, and Geo. S. Henry.

For the City—Messrs. J. J. Ward, and L. H. Clarke.

For the Province—Mr. W. G. Trethewey.

The County By-law appointing Commissioners included the Warden of the County by virtue of his office, hence in January, 1912, Mr. Bull was succeeded on the Commission by Mr. John Gardhouse, Warden for 1912.

The following is the engineer's report:

My first report, which was presented to you in December, 1911, outlined generally the work we had undertaken, but as this report is our first printed report, I am incorporating in it part of the work undertaken during 1911, as well as dealing more particularly with the work of this year. When we commenced construction work in 1911 we had great difficulty in securing contractors who were experienced in road building, and where we undertook to do the work by day labor we had greater difficulty in securing men who had experience in the construction of waterbound macadam highways.

That the work might not be delayed and that the Commission might have in their possession information as to the cost of construction, it was decided that in 1911 to purchase two outfits. These outfits were so successful in 1911 that in the spring of 1912 three more were purchased. The five outfits purchased, together with the contractor's equipment, made it possible for the Commission to put in the field during 1912, fourteen outfits.

YONGE STREET.

Road No. 1., Div. 11 and 12.

This section was completed by day labor with Ben. Flook immediately in charge of the work.

Double Cylinder Waterous Roller, Working on Yonge Street.

In 1911, a Waterous double cylinder 12½-ton roller was used, and in 1912 a Kelly-Springfield double cylinder 12½-ton gasoline roller was used.

With the exception of a short section opposite lots 15 and 16, which was built of limestone, the road is constructed of 2-inch granite from Washago, waterbound with limestone screenings, and the road has an average width of 15 feet.

From an observation of the wear on the limestone and on the granite, it would appear that the granite will give much better service.

The granite on this road cost $1.75 per ton f.o.b. Metropolitan Railway sidings.

The limestone cost $1.95 per ton. The high price of limestone was due to the fact that there are no limestone quarries on the C.N.O. Ry. and that this stone had to come over three railways, thus making us liable for three freight rates.

The following tabulated statement will give at a glance the [illegible] and charge:

YONGE ST. DIV. 11 AND 12—MR. BEN. FLOOK.

	Total Cost 1911 & 1912	T't'l tons (1 ton $1.75)	T't'l c.yds. (2600 lbs. to c. yd.)	Cost per c. yd.
Grit, stone and granite..	$20,982.62	11,990	9,223	$2.27
Labor	5,412.26			58 3/5c.
Teams	3,066.43			33 2/10c.
[illegible]	457.96			4 9/10c.
Oil & accessories for roller	64.24			7/10c.

YONGE STREET.

Road No. 1, Divs. 13, 14 and 15.

These sections were completed by day labor with John Sheardown in immediate charge of the work.

In 1911, a small section was completed in the Village of Richmond, but it was not until 1912 that much progress was made.

These divisions were built of granite from Washago, waterbound with limestone screenings, and the road has an average width of 15 feet.

The remarks as to wear and cost given under Divisions 11 and 12 apply in Divisions 13, 14 and 15.

YONGE ST. DIVS. 13 AND 14—MR. J. SHEARDOWN.

	Total Cost 1911 & 1912	T't'l tons (1 ton $1.75)	T't'l c.yds. (2600 lbs. to c yd.)	Cost per c. yd.
Grit, stone & granite.	$18,139.82	10,365.6	7,973.5	$2.27
Labor	4,164.24			52 2/10c.
Teams	2,705.50			33 9/10c.
Coal & wood	327.82			4 1/10c.
Oil & acc. for roller..	52.88			66/100c.

KINGSTON ROAD.

Road No. 2, Divs. 21 and 22.

This road was built by contract.

Contractor, Morris Reid, Dunbarton, Ont.

In the construction of this road limestone from Dundas and Kirkfield was used. It was waterbound with limestone screenings.

Although this road had been previous a stone road, the road had been left without repair and the traffic had been so heavy that for most of the road we had to commence at the sand and build up again so that it made it an expensive road using much material.

The road is well crowned, and well bound, anl well drained, and is built with an average width of 14 feet from the east city limits to lot 21, Con. C., Scarboro.

KENNEDY ROAD.

Road No. 3, Divs. 31 and 32.

This road was built by contract.

Contractors:

ROUTLEY & SUMMERS, Haileybury, Ont.

In the construction of this road limestone from Dundas and Kirkfield was used; it was waterbound with limestone screenings.

On one section of this road just south of the C.N.O. Ry. tracks a short section was surfaced with trap rock from Cobalt. This road is much more expensive to lay than limestone, but its wearing qualities are much superior, and I anticipate that in future large quantities of trap rock will be used for macadam highway. Trap rock will cost from $1.85 to $1.95 per ton, f.o.b. sidings, in York County.

On this road 15 ft. of 4-inch tile was laid.

Three concrete culverts was constructed with openings of 4-inch, 6-inch, 3-ft. and 3-ft.

This road is completed from the east city limits to lot 23, Con. D, Scarboro. The metal part of the road has an average width of 14 feet.

KENNEDY AND MARKHAM ROAD, UNIONVILLE.

Comprising parts of Division 34, Kennedy Road, No. 3, and Divisions 92 and 93, Markham side road No. 9.

Finished road extends on Con. VI., Markham, from lot 6 to lot 14, inclusive, also from G.T.R. track, Unionville, east to Con. VII. and a quarter-mile on Main Street, Markham Village.

This work was conducted by day labor, W. Huber in charge.

Total length of road finished 4 miles, varying from 10 to 16 feet in width, having a total area of 25,066 square yards.

This road is constructed of Kirkfield limestone, the material averaging 2 in. in size, waterbound with limestone screenings.

A large part of this work was done on a soft sub-grade, rendering satisfactory binding very difficult. Other difficulties were inability to secure sufficient stone to keep the work in progress, and much wet weather. In spite of these drawbacks, however, the cost of the road compares very favorably with those done by contract. Saved by doing the work by day labor as against contract prices. On this road a total of 5,100 feet of tile drain was laid at a cost of $300.

The total cost of material and labor was $15,000, being at the rate of less than 60 cents per square yard.

A total of 5,320 cubic yards of material was used, making the finished road cost at the rate of $2.82 per cubic yard. These figures clearly demonstrate the saving due to day labor methods.

WESTON ROAD.

Road No. 7, Divs. 72, 74, 75 and 76 (parts of).

The southern part of section 72 was built by contract.

Contractor, E. C. Lewis, Toronto, Ont.

The southern section of this road, the Black Creek Hill, receives very heavy traffic and as the hills were sandy it was thought best to use a concrete base with brick surfacing, and this has been done. At first the teamsters were afraid that this hill would be very slippery, but experience has shown that the brick has made an excellent road where, before, the highway was practically impassable.

From the Black Creek Hill north the work was done by day labor, James Gardhouse, Weston, Ont., being in charge.

The road is built of limestone waterbound with limestone screenings, average width 16 feet.

The Village of Weston are putting in a sewerage system, so that we could not build the road through the village.

From the North Boundary of Weston to the Etobicoke River, the road is built of limestone 13 feet wide.

The work in Divs. 75 and 76 was also done by day labor under Mr. Gardhouse.

The material used was an extremely hard granite from Coldwater, but the quarries on the C.P.R. were closed down for such a long period that very little work was accomplished in this section. There are three quarries opening at Coldwater this year, and it is possible that shipments during 1913 to Woodbridge will be more regular and satisfactory.

LAKE SHORE ROAD.

Road No. 4, Div. 41.

This road was built by contract.

Contractors, J. H. McKnight & Co., 152 Bay St., Toronto.

Dolarway Pavement, Lakeshore Road.

During 1911 no work was done on this road, but from the first it was recognized that the character of the traffic here was such as to require an exceptionally strong pavement.

In June, 1912, a contract was let for a pavement with a concrete base 7 in. thick and surfaced with a bituminous preparation. The contractors undertake to maintain this pavement for three years.

Owing to the impossibility of keeping the traffic off the concrete, and the damp season, a good surface was not secured; but from the experience of the contractors on other sections of similar road, I am confident that next season they will get a good surface on this concrete. I am persuaded that our experience on the Lake Shore Road will lead to the adoption of permanent construction on our leading highways.

The Lake Shore Road is completed from the west city limits to within some 400 feet of Church Street, Mimico. The concrete is 15 feet wide with 3-ft. earth and stone shoulders on each side.

VAUGHAN ROAD.

Road No. 6, Div. 61.

This road was built by contract.

Contractor, E. G. Law, 74 Glenwood Ave., Toronto.

When the work was commenced on this road the teaming had to be done from Downsview Station. Later arrangements were made to ship in on the Belt Line.

This road is built of limestone with an average width of 14 feet. Because of the impossibility of securing stone, the contractor was not working one-third of his time this season.

Div. 64.

Work was commenced here by day labor with Mr. D. Watson in charge.

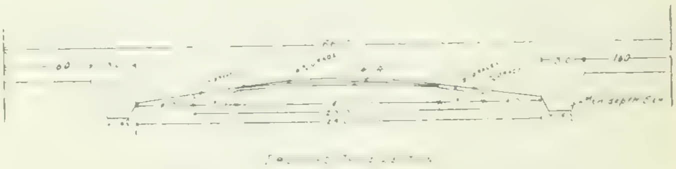
When work was commenced we were promised plenty of stone from Orillia, but the quarry was not well laid out and could only ship one car per day, and later only one car every other day. Arrangements are being made for the opening of three quarries on this line next year so that we should be able to get plenty of stone here in 1913.

SUMMERVILLE ROAD.

Road No. 5, Divs. 51 and 52.

Div. 51 was built by contract, Routly & Summers, Haileybury, Ont., being the contractors.

From the city limits to the Humber Bridge this road was built with an average width of 15 feet of limestone and waterbound with limestone screenings.



General Cross-Section of Improved Roads.

Before the traffic had used the road, the road was treated with Tarvia B., and I have no doubt that the splendid condition of this road is due to the prompt treatment it received. Although this road takes extremely heavy traffic, and although it is showing some wear, yet not a single rut has developed and the road is wearing uniformally smooth.

Div. 52.

This division was built by contract, the contractor being I. M. Scott, Lambton Mills, Ont.

This division being a continuation of the section of Dundas Street built by the T. Eaton Co., it was thought wise to build a section of road with a special binder. Rocmac was used for binding this road. The material used was limestone and our experience here has led us to believe that trap rock bound with Rocmac is going to give an excellent class of construction for leading highways.

DON MILLS ROAD.

Road No. 8, Divs. 81, 82 and 83.

This road was built by contract.

Contractor, B. F. Law, 143 Kingston Road, Toronto.

A small section of Division 81 was built of limestone.

The road in Divisions 82 and 83 was built of granite, waterbound with limestone screenings.

In the foregoing report I have outlined briefly the condition of work on the various roads.

Up to the present time we have given our attention to the roads near the City of Toronto, and, of course, because of the nature of the traffic, they have taken more time and more money to build than will the roads that remain.

Transmission Line Construction. Methods and Costs. By R. A. Lundquist, E.E., Consulting Engineer, Minneapolis, Minn. New York: McGraw-Hill Book Co. Cloth; 5½ x 7¾ in.; 285 pages; 180 illustrations and diagrams. Price, $3.00 net.

The reading matter is divided into thirteen chapters having the following tables: Preliminary Work; Location of Line; Types of Construction; Wooden Pole Construction; Steel Pole Construction; Steel Tower Construction; Reinforced Concrete Construction; Special Structures; Cross-arms; Hardware; Pins and Insulators; Guying; Stringing Wire; Cost Data of Typical Transmission Lines; Organization and Tools; Standard Specifications for Line Apparatus and Material (Appendices).

The author's intention, as set forth in his preface, was to deal exclusively with the practical side of transmission line construction. This he has done to such good purpose that his book will form a timely and most acceptable addition to the engineer's library, the more so as such information as was heretofore available on this subject was in the form of miscellaneous articles in the technical press.

The outstanding feature of this book is the manner in which the author has supplemented his descriptions of the various stages of transmission line construction by an immediate reference to cost. His description of the method of distributing poles is followed by figures relating to the cost of distribution; a very clear and comprehensive description of various methods of setting steel tower footings is supplemented by a compilation of figures covering the cost of this class of work in various parts of the United States and Canada, and so on.

In the matter of costs, also, there is evidence of a conscientious effort on the part of the author to qualify his statements by reference to the variable factors affecting the same, such as labor rates, seasons, topographical and geographical conditions. Without these references the large amount of cost data which the book contains would be rather a source of danger than of benefit to the average reader

Chapters III., VI., IX. and XI. contain valuable data and descriptions, appropriately illustrated, in connection with the construction of modern high-tension steel tower transmission lines with suspension type insulators. In chapter IV. various methods of treating wood poles with preservative compounds are described and costs specified. Chapter VII. contains, among other things, a very interesting description of the manufacture of hollow reinforced concrete poles by the centrifugal process.

The text is interspersed with numerous useful references to articles that have appeared in the technical journals, and there is nothing in the book which could not be comprehended or put to practical use as well by the construction foreman as by the engineer.

The author is slightly in error in stating, with reference to Fig. 114, that "the towers are the standard anchor structures and the equipment the same as at regular strain tower installations." The middle tower in the illustration referred to happens, in this case, to be a transposition tower and not a standard anchor tower. A "typical" railroad crossing on the line in question would have two towers of the type shown in the foreground of the illustration. The "equipment" at these crossings differs from the regular strain construction in that the crossing conductors are doubled and tied every six feet, and a special form of double-strain clamp is used for supporting the doubled conductors.

Also on page 207 the author states that suspension type insulators must "necessarily" be attached to steel towers subsequent to their erection. It is quite feasible and in many cases much more economical, to attach the insulators to the towers before erection.

An Extension of the Dewey Decimal System of Classification Applied to the Engineering Industries. By L. P. Breckenridge and G. A. Goodenough. Originally issued as Bulletin No. 9 of the Engineering Experiment Station in 1906. Price 50 cents.

The filing and classification of engineering data has become a matter of much importance, and this bulletin was prepared for use as a guide in carrying out such work. The original edition of Bulletin No. 9 was subject to the usual gratuitous distribution, and the subsequent demands were such that a second edition was printed and ultimately distributed. Altogether 20,000 copies were sent out. The demand having continued, it was finally decided again to revise and to print a limited edition. This has now been accomplished and the revised bulletin, much extended as compared with the original edition, is ready for distribution. It presents subdivisions of subjects in such detail as to constitute a complete classification for most engineering industries, even though they are highly specialized. The revision has been made in accordance with the 1911 edition of "Decimal Classification," by Melvil Dewey.

A Treatise on the Design and Construction of Roofs. By N. Clifford Ricker, professor of architecture, University of Illinois; president, Illinois Board of Examiners of Architects, etc. New York: John Wiley and Sons; London: Chapman and Hall, Limited. Publishers' Canadian agents, Renouf Publishing Company, 25 McGill College Avenue, Montreal. Cloth; 6 x 9¼ in.; pp. xiii. + 419; 644 text figures. Price, $5.00, net, (21/- net).

The evident intention of the author in preparing this book was the assistance of junior designers and architectural draughtsmen, rather than the making of a notable contribution to the knowledge of structures. His work is, therefore, less valuable to the specialist in structural engineering than to the beginner. For those who require each step to be carefully indicated and each case treated specially, the guidance and instruction obtainable from this book will be invaluable. It is an excellent presentation in orderly and usable shape, of a large mass of information which, in the main, is available from other sources.

The author's method of treatment is very properly shaped to the purpose he has in view, in that instruction is given largely by numerous examples fully worked out, with each step carefully recorded. Considerable repetition thus characterizes the work, which perhaps will not be found objectionable by those who will use the book most.

As an introduction to the subject, three chapters are devoted to Graphostatics, Construction of a Trussed Roof, and Loads on Roof Trusses. The author then proceeds to obtain by graphical means the stresses in roof trusses of twenty-four different types of all grades of complexity, including combinations of cantilever trusses and monitors and an octagonal hip roof with lantern. For ease of reference there is assembled in Chapter V. outline and stress diagrams of a large number of roof trusses of both common and rare occurence. The method of moments is illustrated by one problem, thus affording to the student a comparison of graphical and analytical methods. An indication of the elementary character of much of the matter in the book is seen in chapter VII., in which 37 pages are devoted to the calculation of the lengths of members of roof trusses. Chapter VIII. concerns the stability of the supports of roofs under wind pressure, and contains a useful discussion of the resistance of walls to eccentric loading. Then, as a basis for the proportioning of truss members and details later, the simpler data of strength of materials and details of wood and steel construction are discussed in one chapter. Considerable valuable information in tabular form is given in chapter X., such as the safe loads on steel tension members of various make-up, safe loads on compression members of both steel and wood, properties of wooden beams, strength and weight of details, etc. The tables for the strength of wooden members would have been somewhat more useful if the net dimensions of the timber, after dressing, had been used. Dimensioning of members and the detailing of connections receive attention in chapters XI. and XII. Probably the one really bad feature of the book is the grotesque details of the steel roof trusses. Gusset plates of the most irregular shape and angles with all kinds of skew cuts are employed, with the result that trusses detailed according to the models set forth would cost more than their purchasers would care to pay for them and be no better than those conforming to the best bridge shop practice. The book is concluded by chapters on Deformations and Estimates of Weight.

Some rather unusual terms are employed in the text. For example, the author speaks of loads being "equilibrated," of balancing force as "antiresultant," of section "moduluses," etc.

Despite its somewhat high price, a large sale, among architects particularly, should be experienced for the book.

Water Supply and Drainage. By C. E. Housden. Published by Longmans, Green & Co., 39 Paternoster Row, London. Canadian agents, Renouf Publishing Co., 25 McGill College Avenue, Montreal. Cloth; size, 4¾ in. x 7¼ in.; 28 pages. Price, 45 cents.

This small volume is a supplement to the same author's book on "The Precise Calculation of Pipe Drain and Sewer Dimensions," which was reviewed a few months ago in these columns. The idea of this little volume is to afford a ready means for ascertaining precisely the dimensions of pipes, drains or sewers to be used for a projected water supply or drainage system. With the original work and the tables therein, this book should form a very valuable adjunct to the library of the engineer interested in sewerage work.

The Indicator Handbook, Part II. By Charles N. Pickworth. Fifth edition. Published by Emmatt & Co., 65 King Street, Manchester, England. Price, 90 cents, net.

When a small handbook such as this reaches its fifth edition it may be taken for granted that most of its earlier faults have been eliminated, and that it has satisfactorily supplied a want and proved its worth.

Part I of the book deals with the indicator itself, whilst the section now under review is devoted exclusively to the indicator diagram.

The subject is treated in a very concise and practical manner, leaving little to be desired, and illustrations show the peculiar curves obtained under faulty or abnormal conditions of working.

Chapter I. is explanatory and describes various methods of constructing theoretically perfect diagrams for saturation and adiabatic curves.

In chapter II. the different periods of the indicator diagram, viz., the admission, steam, expansion, release, exhaust and compression lines are severally discussed, while chapter III. deals with the effects of variations of lap and of valve travel, and defective valve setting, leakage, under and overloading of engines, etc.

Compound steam engine diagrams and those from gas and oil engines are taken up in chapters IV. and V., and in the next, diagrams from air compressors, pumps, etc. Very interesting are the diagrams given in the latter chapter illustrating faulty working of boiler feed pumps, etc.; leakage past the plungers, defective valve action, etc., can be readily detected from the shape of the diagram.

* Consulting structural engineer, 318 Continental Life Building, Toronto.

* With Ontario Hydro-Electric Commission, Continental Life Building, Toronto.

Chapter VII., the last, is headed "Diagram Calculation," and describes various methods which may be employed to ascertain all the information which a diagram is capable of supplying.

An appendix, containing several useful tables, and an index bring to a close a book which would be very serviceable to anyone whose duties require him to investigate the working of reciprocating plant.

Building Stones and Clay Products. A Handbook for Architects. By Heinrich Ries, Ph.D., Professor of Economic Geology in Cornell University. Published by John Wiley & Sons, New York. 428 pages; 6 x 9 in.; well illustrated; cloth. Price, $3.00.

This book will prove to be very valuable to the architectural profession for which it has been written. The author, Professor Ries, an eminent geologist, has realized our limited knowledge of mineralogy, geology and ceramico, and as a result his simple statements of facts, together with the necessary explanations, will be appreciated. His classification of the building stones has been made with the same desire for simplicity, and to further aid the reader he has provided a very complete index and an excellent glossary.

Throughout the book, whether in the chapters on the Rock Forming Minerals, the Granites, the Sandstones, Limestones, Marbles, or Clay Products, there is no sign of a desire on the part of the author to tell all he knows of these different materials, but always the plain intention to analyze the subject so as to give the architect the information he is looking for.

The second part of the book contains a complete and yet elementary description of the properties of clay, the methods of its manufacture into bricks, terra cotta, hollow-ware, tile, sewer pipe and sanitary ware, which will assist any architect to select and use these materials more intelligently.

It may be said by some that this book in Part I. is largely describing building stones that are quarried and manufactured in the United States, but the fact remains that at the present time there is imported into Canada a large amount of freestone, limestone and marble from Ohio, Indiana and Tennessee, etc.

The production of building stone in 1911 in Canada was $1,988,757; the stone imports were $1,140,846, of which most came from the United States.

Successful Homes and How to Build Them. By Chas. E. White, Jr. Published by The Macmillan Company, New York and Toronto. Cloth; 5 x 7¾ in.; 520 pages, including index; profusely illustrated with Photographs and line drawings. Price, $2.00, net.

This book, while written from the standpoint of the house-owner, will be found of considerable interest by the architect, the builder, and the engineer who contemplates a house for himself. The volume covers, authoritatively and completely, the entire field of building houses, large and small. The general make-up of the book is in line with the high standard of the Macmillan publications.

Each factor bearing on the erection and equipment of a house is taken up in order, beginning with the purchase of the site and the letting of the contract. The various building materials, arrangements of rooms, the different kinds of heating, ventilating and lighting systems, decorating inside, painting outside, are all fully treated. Consideration is devoted to city houses, town, country and farm houses, suburban houses and bungalows, camps, cottages, garages, barns and green houses. There are also several chapters on out-door accessories, such as terraces, walls, banks, sidewalks and pergolas.

Street Paving and Paving Material. By G. W. Tillson, C.E. Published by John Wiley & Sons, New York. Cloth; size, 6 in. x 9 in.; 650 pages; 97 figures. Price, $4.00.

This is the second edition of a manual on street pavement. It gives methods of construction and the materials suitable for the various classes of pavement. The publication is extremely useful, not only to students and engineers, but to city officials generally.

The first edition was published in 1900, when the author, after 20 years' experience, particularly in pavements, produced the book in order to show not only the evolution of the modern city streets, but also what was being done at that time in pavement construction. The following pavements are dealt with: Stone; Asphalt; Brick-Clays and the Manufacture of Paving-Brick; Cement, Cement Mortar and Concrete; Cobble and Stone-Block Pavements; Asphaltic Pavements; Brick Pavements; Wood Pavements; Broken-Stone Pavements; and Concrete Pavements.

In addition, the author deals with the theory of pavements; Plans and Specifications; the Construction of Street-Car Tracks in Paved Streets; Width of Streets and Roadways, Curbs, Sidewalks, etc.; Asphalt Plants.

Since this work was originally given to the public a number of new pavements have been introduced and the methods of constructing the old have been so modified as to render necessary a pretty complete revision of certain chapters and the addition of a new chapter on concrete pavements. No attempt has been made to deal with road construction.

A chapter has been added on the protection of pavements. This is a matter that must be given serious attention in this country, where it seems necessary to have a great deal of subsurface street construction. This chapter will be of benefit to engineers who are about to take this matter under consideration.

Fourth National Conference Proceedings. Published by the association, office of secretary, 19 Congress Street, Boston, Mass. Cloth; 6 x 9½ in.; 232 pages. Price, $2.00.

This volume includes the proceedings of the Fourth Annual Conference on City Planning, held at Boston, Mass., May 27-29, 1912. These volumes are published by subscription, but there are a limited number to be had at the above price of $2.00. The precedent of former volumes has been followed in presenting the chief papers read at the conference in full, and condensing or summarizing the discussions.

Boundaries and Landmarks. By A. C. Mulford. Published by D. Van Nostrand Company, 25 Park Place, New York. Cloth; size, 5¼ x 8¼ in.; 90 pages. Price, $1.00.

This manual is intended to familiarize the surveyor with the different types of old boundaries that exist throughout the United States. It is written to provide a useful treatise in connection with the conveyances of the Eastern States.

* Professor of Architecture, University of Toronto, Toronto.

* Engineer to the York County Highway Board

Reviewed by H. P. Bell.*

Bleaching and Dyeing of Vegetable, Fibrous Material. By Julius Hübner, M.Sc., Tech., (Manchester). Published by D. Van Nostrand Company, 25 Park Place, New York. Cloth; 5¾ in. x 9 in.; 434 pages. Price, $5.00.

Mr. Hübner's book is, as the author states, a practical handbook intended for the use of working dyers. The chemistry and physics of dyes and dyeing are touched on only so far as is necessary to explain the methods and machinery which are described. A large part of the book is devoted to lists of dyestuffs now in use and directions as to the methods with which the best results may be obtained with them. These directions are, as the author points out, largely taken from the books issued by the various makers of dyestuffs, but they are here placed together in a way which makes it easy to compare the methods and to select those which are best for particular materials or particular purposes. The newest forms of machinery are very clearly described, not only in connection with the processes in which they are used, but also in a separate chapter, and the illustrations which accompany the descriptions deserve special mention for their excellence. Instead of the photographs of machinery, which are too commonly used in technical books, the present illustrations consist of sectional drawings and sectional diagrams, many of which are printed in two colors, so that the cloth or yarns passing through the machines is distinguished by being printed in red.

Besides the processes of dyeing, Mr. Hübner deals with bleaching, washing and mercerizing, and there are chapters on the testing and softening of water, the testing of dyestuffs and fibres, and the chemicals and mordants in general use, for many of which the current English prices are given. The book also contains a number of useful tables and an excellent index, and is likely to be valuable, not only to dyers and students of dyeing, but to engineers who have to do with machinery for the processes referred to.

Text Book on Roads and Pavements. By Frederick T. Spalding, professor of Civil Engineering, University of Missouri. Published by the McGraw-Hill Book Company, New York. Fourth edition, 1912; cloth; size, 5 x 7½ in.; 408 pages; 51 figures. Price $2.00.

The size of this book has been increased about twenty per cent. with this edition. New chapters are added on bituminous, macadam and concrete pavements, and the chapters on brick, asphalt and wood pavements have been thoroughly revised. While the general character of the book has been very little altered, the advances in the method employed in the construction and maintenance of highways has rendered a number of changes necessary. The book has now been brought thoroughly up-to-date and in accordance with present practice.

Smoley's Tables. By Constantine Smoley, C.E. Published by McGraw-Hill Book Company, New York. Seventh edition, revised and enlarged; flexible leather; size, 4½ in. x 7 in. Price, $3.50.

These parallel tables of logarithms and squares, diagrams for solving right triangles, angles and logarithmic functions corresponding to given bevels, common logarithms of numbers and tables of logarithmic and natural trigonometric functions and other tables, for engineers, architects and students, are too well known to need much comment. The tables have with this issue reached the seventh edition. In this edition a special device has been added for solving right triangles of comparatively small dimension. The device is a diagram which will enable the user, after a little practice, to obtain almost at a glance results that are sufficiently accurate for most practical purposes.

CATALOGUES RECEIVED.

Cooling Towers.—Edwin Burnorn & Company, 71 Wall Street, New York City, forward catalogue illustrating their "Burnorn" and "Acme" cooling tower.

Water Meters.—The Buffalo Meter Company, 290 Terrace, Buffalo, N.Y., forward copy of their 1912 catalogue of American and New Niagara Water Meters.

Boilers.—Fraser & Chalmers, Limited, 4 Philips Place, Montreal, P.Q., forward catalogue illustrating installations of the Bettington Boilers (water tube) for atomized fuel.

Pipe.—The National Tube Company, Pittsburg, Pa., forward N.T.C. Bulletin No. 11, which describes the Spellerizing process used in the manufacture of their pipe.

Turbo-Alternators.—The Canadian Westinghouse Company, Limited, Hamilton, Ont., Railway and Lighting Department, forward Circular No. 1094, illustrating and describing Westinghouse turbo-alternators.

Dynamos.—The Engineering Works of Canada, Limited, New Birks Building, Montreal, forward catalogue illustrating dynamos manufactured by Societe Alsacienne de Constructions Mecaniques, Belfort, of which they are the Canadian agents.

Non-Pulsating Pumps.—The General Machinery Co., Limited, 22 to 26 Mulock Avenue, West Toronto, forward the last catalogue describing the Luitwieler System of Non-Pulsating Pumps, manufactured by the Luitweiler Pumping Engine Company, Rochester, N.Y.

Concrete.—The Canada Cement Company, Limited, Montreal, forward copy of book recently issued, entitled "What the Farmer Can Do With Concrete." Copies may be secured by addressing Mr. L. S. Bruner, Manager of Publicity, Canada Cement Company, Montreal.

Powell Wood Process.—The Powell Wood Process Syndicate, Limited, through their selling agents, Messrs. Boving & Co., Limited, 9½ Union Court, London, E.C., have forwarded a booklet describing the Powell wood process for rapidly seasoning, preserving and improving wood.

Motor Truck Tires.—The Dunlop Tire and Rubber Goods Company, Limited, Toronto, forward their catalogue K-3, entitled "Dunlop Quick Removable and Band Type Motor Truck Tires," which contains price list and description of their different types of tires.

Steel Reinforcement.—The Standard Concrete Steel Company, 413 East 31st Street, New York, forward copy of their pamphlet, entitled "System M," of which this is the second edition. The pamphlet describes the system developed by this company for the steel reinforcement of reinforced concrete buildings.

Sewage Sprinklers.—Jones & Attwood, Limited, of Stourbridge, England, manufacturers of the Fiddian waterwheel type of sewage sprinkler, have forwarded a booklet describing these sprinklers. This booklet is a special edition for municipal engineers. Copies may be secured from The Canadian Engineer, 62 Church Street, Toronto.

Steel Pipe.—The East Jersey Pipe Company, of 50 Church Street, New York City, forward their last catalogue, containing recent photographs and data of interest in connection with the use of their lock-bar pipe and riveted steel pipes. Copies may be secured by addressing the company.

Measuring and Mixing Machine.—W. J. Fraser & Company, Limited, Dagenham, Essex, England, the sole licensees and manufacturers for Great Britain and the colonies of the Trump Measuring and Mixing Machine and the Trump Concrete Mixer, forward catalogue describing the operation of these machines.

Blueprinting.—The C. F. Pease Company has issued a 32-page booklet, entitled "Everything for Blueprinting," describing and illustrating various types of the Pease peerless blueprinting machines and equipment, the Pease simplex and duplex paper-coating machines and washing and drying machines and other equipment for use in the handling of blueprints.

Hydro-Pneumatic Sewerage System.—Hughes & Lancaster, Limited, sole licensees and manufacturers of the "Shone" patent Pneumatic Automatic Ejector, forward catalogue, entitled "The Shone Hydro-Pneumatic Sewerage and Water System," illustrating different installations of their ejectors. Copies may be secured from Hughes & Lancaster, Limited, 16 Victoria Street, London, S.W.

Logging Machinery.—The Clyde Iron Works, of Duluth, Minn., forward their new catalogue of Clyde Self-propelling Logging Machinery. The book is 9 x 12 in. in size, and contains 92 pages. It is profusely illustrated with very fine half-tones, illustrating different types of logging machinery. The pamphlet is beyond question one of the most artistic which has come to this office. Copies may be secured from the Clyde Iron Works, Duluth, Minn.

IRON ORE PRODUCTION.

There has been a rapidly growing demand for iron and steel products in Canada during the past few years, accompanied by a corresponding increase in the output of Canadian iron and steel furnaces, although this output probably supplies not more than 30 per cent. of the tonnage of iron and steel consumed.

The increase in production was continued during 1911, notwithstanding abnormally low prices received for pig iron and steel products, states Mr. J. McLeish, chief of the division of mineral resources and statistics in his latest report. Manufacturers, generally, report a very strong demand, but claim that business has been carried on with a very low margin of profit in order to meet prices quoted on imported products.

At the same time extensive preparations are being made to increase the output and supply a larger proportion of the home market.

The total shipments of iron ore in 1911 from mines in Canada were 210,344 tons, whereas blast furnaces consumed 1,695,802 tons, and steel furnaces, 42,892 tons. The shipments from iron ore mines in 1911 were the lowest recorded in twelve years. The production of pig iron was 917,535 short tons, and of steel ingots and castings, 882,396 tons.

The rate of production of iron ore has shown practically no increase during the past twelve years, while the present production of pig iron is nearly ten times that of 1900. About 6 per cent. only of the iron ore used in Canadian blast furnaces during 1911 was of domestic origin. Of the coke used, 52 per cent. was either imported or made from imported coal, and 22 per cent. of the limestone flux used was from sources outside of Canada. In each instance the proportion of imported raw material used is higher than was the case in 1910.

The total production of iron ore in Canada to the end of 1910 has probably not exceeded 5,500,000 tons, while the total consumption of ore in iron and steel blast furnaces since 1886 has been over 13,500,000 tons. During 1911 the tonnage of imported ores used was 1,628,368 tons, which was derived chiefly from Newfoundland and the south shore of Lake Superior.

The assistance granted by the Federal Government to the iron and steel industries in the form of bounties ceased on December 31, 1910, with the exception of the bounty on steel rods, which was continued to June 30, 1911, and the bounty on pig iron and steel made in electric furnaces, which is available until the end of this month.

IMPORTANCE OF CANADA'S CEMENT INDUSTRY.

The production of cement in Canada during the past few years though all classed as Portland, has included an output of Puzzolan cement, made from blast furnace slag at Sydney, N.S., and a small production of "natural Portland" made at Babcock, Manitoba, 75 miles southwest of Winnipeg on the Canadian Northern Railway. The total quantity of cement made in Canada during 1911, as per reports received from the manufacturers, was 5,677,539 barrels of 350 pounds net each, or 993,569 tons, as compared with 4,396,282 barrels, or 769,349 tons, made in 1910—an increase of 1,281,257 barrels, or over 29 per cent, states the report of Mr. J. McLeish, B.A., chief of the division of mineral resources and statistics.

The total quantity of Canadian Portland cement sold in 1911 was 5,692,915 barrels, or 996,260 tons, as compared with 4,753,975 barrels, or 831,946 tons, in 1910, an increase of 938,940 barrels, or nearly 20 per cent.

The total production of Portland cement in 1911, including Canadian and imported cement, was 6,354,831 barrels of 350 pounds net, or 1,112,095 tons, as compared with 5,103,285 barrels, or 893,075 tons, in 1910—or an increase of 1,251,546 barrels or nearly 25 per cent.

The cement industry has been rapidly growing in importance, and its output is now exceeded in value amongst nonmetallic products by coal and clay products only.

An average of 3,010 men were employed in 1911, the total wages paid being reported as $2,103,838.

The increase in annual production since 1905 has been nearly four-fold. The production per capita in 1911 was about 278 pounds, as against only 79 pounds in 1905. The approximate consumption per capita has increased during the same period from 115 pounds to 310 pounds.

A similar rapid increase in both production and consumption has taken place in the United States, where the annual production now exceeds 75,000,000 barrels.

The production per capita in the United States was in 1910 about 332 pounds, as against 204 pounds in 1905.

The production of cement in 1911 was derived from 24 operating plants, having a total daily capacity of $28,281, the operating plants being distributed as follows: one in Nova Scotia, using blast furnace slag; one in Manitoba, making a natural Portland cement; one in British Columbia; three in Alberta; three in Quebec, using limestone and clay; and fifteen in Ontario, of which twelve use marl and three limestone.

Of the total quantity of cement made in 1911, 1,626,857 barrels were made from marl and 4,050,682 barrels from limestone and slag. In 1910, there were 1,214,479 barrels made from marl and 3,181,803 barrels from limestone and slag, and in 1909, 819,706 barrels were made from marl and 3,336,002 barrels from limestone and slag. Practically all of the newer plants erected during the past few years have been limestone plants. The proportion of cement made from marl in 1908 was about 45 per cent. of the total output, as compared with about 28 per cent. in 1911.

The consumption of cement is represented practically by the domestic production together with the imports, the exports being so comparatively small as to be negligible. The total consumption of Portland cement in Canada in 1911 was 6,354,831 barrels (1,112,095 tons), made up of 5,692,915 barrels (996,260 tons) of Canadian cement, and 661,916 barrels (115,835 tons) of imported cement; the Canadian cement representing 90 per cent. and the imported cement 10 per cent. of the total.

In 1910 the total consumption of cement was 5,103,285 barrels (893,075 tons), of which 93 per cent. was of domestic production and 7 per cent. imported. In 1901 the total consumption was 872,966 barrels (152,769 tons), of which only 36 per cent. was made in Canada and 64 per cent. imported.

The following is an estimate of the annual consumption of Portland cement in Canada during the past eleven years:—

Calendar Year.	Canadian		Imported.		Total.
	Barrels	%	Barrels	%	Barrels
1901	317,066	36	555,900	64	872,966
1902	594,594	52	544,954	48	1,139,548
1903	627,741	45	773,678	55	1,401,419
1904	910,358	54	784,630	46	1,694,988
1905	1,346,548	59	918,701	41	2,265,249
1906	2,119,764	76	665,845	24	2,785,609
1907	2,436,093	78	672,630	22	3,108,723
1908	2,665,289	85	469,049	15	3,134,338
1909	4,067,709	97	142,194	3	4,209,903
1910	4,753,975	93	349,310	7	5,103,285
1911	5,692,915	90	661,916	10	6,354,831

The effect of a by-law passed by the Cobalt town council is to repeal, in part, a previous $50,000 waterworks and sewerage system by-law. Of the $50,000 worth of debentures, only $6,500 were sold, when it was found unnecessary to dispose of the rest. The sanction of legislature will be applied for, for the cancelling of the other $43,500, as that had to be gained before the previous by-law was passed.

COAST TO COAST.

Winnipeg, Man.—It is probable that the University of Manitoba will establish, in the near future, a course of architecture.

St. Thomas, Ont.—A new system, costing $15,000, for washing out locomotive boilers, is now being installed in the Michigan Central Railway roundhouse here. The transfer table and turntable are now being operated with electricity.

Northern Ontario.—The Bell Telephone Company of Canada recently completed the extension of its long distance lines from North Bay to Mattawa. The circuit is branched in such a manner as to give connection with Bonfield and Rutherglen.

Victoria, B.C.—Mayor Beckworth, in an address to the ratepayers, stated that, in his opinion, the municipal council would have done better regarding the Sooke waterworks scheme to have the work completed under their own engineer by day labor.

Brantford, Ont.—The city engineer, Mr. F. H. Jones, has submitted to the city council a brief statement of the expenditures of the Board of Works for the present year, which totals $117,309; $73,141 was paid out for labor, while the cost of material was $29,368.

Montreal, Que.—The announcement is made that Mr. Farquhar Robertson and Lieut.-Colonel Labelle will be Montreal's new Harbor Commissioners. Mr. Robertson having declined the chairmanship, the third member of the board, who has not yet been appointed, will take that position.

Ottawa, Ont.—The report of the Transcontinental Railway Commission for the fiscal year has been submitted. It shows a total expenditure of $116,517,691 since the organization of the Commission in 1904. This does not include any interest on capital expenditure or any of the expenditure on the bridge approaches. For the fiscal year the expenditure was $21,221,997.

Niagara Falls, Ont.—It is proposed that a large shiplock be constructed in the Chippawa River, connecting it with the new Welland Canal, thus making Chippawa and this city accessable to the largest steamships on the lakes. A resolution was adopted by the City Council of Niagara Falls instructing Mayor Cole to appoint a Greater Niagara Falls Committee, composed of prominent citizens and officials, and also ask the officials of the surrounding townships to co-operate with the city in furthering the project. As originally planned, this lock, which will be large enough to receive any ship afloat on the Great Lakes, was to be placed near the town of Welland. City Engineer Gardiner, however, drafted a plan for the location of the lock in the Chippawa River. If this plan is finally adopted it will give the village of Chippawa and Niagara Falls the rating of a lake port; the largest ships would be enabled to come down the Canadian channel of the Niagara River and then up the Chippawa to the Welland Canal.

Hamilton, Ont.—The Hamilton Malleable Iron Company has been formed with a capital of $600,000, consisting of Toronto, Hamilton and Brantford capital. The names of the officials and directors of the company are withheld, but J. E. Hammond, formerly with Pratt & Letchworth Company, Limited, Brantford, will be one of the directors and assume management of the plant. The new concern will conduct a general malleable iron business, and the output will consist principally of malleable iron castings for railroad, agricultural and miscellaneous work for custom trade. The plant will cost in the neighborhood of one-quarter of a million dollars, and will employ about 500 hands, a large number of which will be skilled mechanics. The main foundry building will be 600 feet long and 200 feet wide. This building will be divided into two bays, with high-speed electric travelling cranes in each bay. In this building will also be located four melting furnaces with a capacity of 15 tons per heat. There will also be located in this building annealing furnaces sufficient to take care of the output; also the latest cleaning and finishing equipment. In addition to the main building will be an office building; also buildings for pattern storage, pattern shop, machine shop, core shop, carpenter shop and storehouse. Paralleling the main building will be an outside crane runway, by which all the raw material for the plant will be unloaded and stored. All the buildings will be of fireproof and modern construction throughout. The equipment will consist of the latest labor-saving devices, such as overhead cranes serving the entire foundry and yard, waste-heat boilers, moulding machines operated by compressed air, finishing equipment, including the latest type of sand blast installation, exhaust tumbling barrels, and all unloading of raw material and loading of finished product will be handled by electric power. The plant will be connected with the railways and have individual tracks leading to and serving the various buildings. The plans for the buildings are being prepared by Prack & Perrine, 36 James Street South, Hamilton, who will also have charge of the construction of the plans and installation of equipment. The plant is being designed in units, which will allow it to be enlarged to double capacity.

COMMON STANDARD LOCOMOTIVES.

Mr. H. H. Vaughan, assistant to the vice-president of the Canadian Pacific, in a discussion of a paper by Mr. O. S. Beyer on "Factors in the Selection of Locomotives in Relation to the Economics of Railway Operation," delivered before the American Society of Mechanical Engineers on December 5th, emphasized the importance of having standard locomotives and maintaining these standards until conditions change so much that it is possible to design another line of standard locomotives, making a distinct step in advance, rather than to modify the standard types from time to time. The time for standardization is before the equipment is built and not afterward. The Canadian Pacific now has about 865 standard locomotives out of a total of 1,800 or 1,900 on the system. It is always possible to introduce changes in the design of standard locomotives, bearing in mind that the new arrangement must be made so that it can completely take the place of the old part for renewals or repairs.

The advantage of standardizing the motive power may be summed up as follows: The standard locomotives can be transferred from one part of the road to another, when business becomes heavy on one section, without having to provide a new storehouse stock, or have the power crippled because of not having the proper parts in stock. It is also possible to keep the shop cost of the engines down because of fewer variations in the size and design of the parts. Where standard locomotives are used it has been found that the division officers are much more likely to offer suggestions as to improvements. Of course, the standardization has disadvantages, one of which is that it is not always possible to immediately take advantage of improvements in the permanent plant. The advantages of having common standards which can be used on any part of the system and with which the men over the entire system are familiar, greatly offset this, however.

VANCOUVER SEWAGE SYSTEM.

It is estimated that the carrying out of the work for the Greater Vancouver joint sewage system will entail an expenditure of $6,000,000. The Burrard Peninsula Joint Sewage System Committee have received the report of Mr. R. S. Lea, consulting engineer, which was practically a synopsis of the final report he anticipates being able to present before the end of the year.

In this report Mr. Lea, states in regard to the matter of population, that he estimates the city's population will have increased to 1,400,000 by the year 1950.

The report states that the most suitable points for discharge would be English Bay, off Imperial Street, about a mile out; Burrard Inlet, at any point except the shore of Coal Harbor between Brockton Point and Evans, Coleman & Evans' wharf; and the Fraser River, where it would be unwise, he states, to fix any point at the present time, but probably the most suitable point would be the low lying land near the Indian Reserve, for the area draining to the North Arm, and the flats near the mouth of the Brunette River for the area draining to that locality.

The lines of the proposed interceptors and trunk sewers are exhaustively dealt with, and refer to the English Bay and False Creek area, showing a foreshore line and an alternative tunnel line; the Balaclava, Bridge Street and Burrard Inlet areas; the Clark Drive, Stanley Park and Hastings Park outfalls; the Burnaby Lake and the Fraser River area.

On the subject of the constitution and powers of a joint board, Mr. Lea states as follows:

"In my final report I shall submit a draft of an act, together with methods of apportionment and assessment, etc., under the provisions of which I consider acceptable ways and adequate means may be found, for the inception, execution and operation of the Burrard Peninsula Joint Sewerage Scheme.

"I hope this preliminary report will give the committee such information as they desire at the present time. My final report, which will really only be an enlargement and elaboration of this present one, together with the data on which my conclusions are based, will be presented to you next month."

THE INTERNATIONAL ROAD CONGRESS.

Formation of a Traders' Committee.

The organization of the International Road Congress, to be held in London in June next, is in the hands of a committee formed of representatives of highway authorities, scientific institutions, learned societies, organizations of automobilists, cyclists, road users and others.

The Organizing Council received some time ago offers of practical assistance from firms and others engaged in the road industry, and it was decided to form a Traders' Committee.

This committee is composed of representatives of all branches of road-makers, including manufacturers of steam rollers and other heavy machinery, road-tarring appliances, stone paving and firms engaged in the construction of bituminous roads, wood-paved roads, quarry owners and others. The president of the committee is Lord Cowdray; the vice-president, Mr. Edward Hickman, J.P.; the chairman, Sir Herbert Praed, and the vice-chairman, Mr. E. B. Chittenden. Other members of the committee are: Messrs. J. W. Ashdown, H. K. Bamber, J. G. Barford, H. D. Blake, H. F. Berry, F. E. Bristowe, F. M. Bond, A. Brooks, W. Chappell, S. Constable, D. G. Comyn, L. Cooper, A. E. Dalzell, J. Duffy, H. T. Elliston, H. Grace, W. T. Graves, W. Penrose Green, T. J. Jennings, J. Mackay, W. Manuelle, T. Milne, P. Morris, H. Pitts, J. Purdy, Gibson Thompson and John Ward. The honorary secretaries are Messrs. H. Beadle and H. L. Wetteim.

The Executive Committee of the Congress will be glad to welcome any further offers of assistance, and to make any additions which may be necessary to secure that all branches of the industry are adequately represented.

AMERICAN ASSOCIATION OF MANUFACTURERS OF SAND-LIME PRODUCTS.

The ninth annual convention of this organization was held on December 3rd and 4th at the King Edward Hotel, Toronto. President S. O. Goho, of Harrisburg, Penn., occupied the chair. There was a large attendance. Among the technical papers presented were "The Results of Testing Sand-lime Brick," by Warren E. Emley, of the United States Bureau of Standards, Pittsburg; "The Present Condition of the Industry," by W. H. Crane. The delegate made an inspection of the local plants of the Toronto Sand-lime Brick Company and the Toronto and Harbor Brick Company, and declared the bricks equal to those manufactured in the large American cities. The election of officers resulted as follows: President, S. O. Goho, Harrisburg, Penn.; vice-president, F. B. Allan, Toronto, Ont.; secretary, W. G. Plummer, Jr., Buffalo, N.Y.; treasurer, John L. Jackson, Saginaw, Mich. Harrisburg, Penn., was chosen as next place of meeting.

CANADIAN MINING INSTITUTE (OTTAWA BRANCH) MEETING.

At a meeting held in Ottawa, December 4th, a branch of the Canadian Mining Institute was organized. The following officials were elected: Chairman, W. R. Askwith; secretary, George L. Burland; executive committee, J. McLeish, G. C. McKenzie, Dr. A. D. Cairns, Robert Harvey and W. J. Dick. Dr. A. E. Barlow, president, and H. Mortimer-Lamb, secretary of the Canadian Institute, gave addresses on the work and aims of the organization.

PERSONAL.

JOHN ROOKE-CROOWELL has been appointed manager of the Cordova mine, in Hastings County, Ont. He was formerly in California and more recently in Mexico.

W. P. NEAR has been appointed city engineer for the municipality of St. Catharines, Ont. For some time he has been resident engineer of the main drainage works, Toronto.

J. P. FORDE, of Revelstoke, for the past two years resident provincial engineer for this district, has been appointed resident federal government engineer for the whole of Kootenay electoral riding in succession to Hon. F. W. Aylmer.

ARTHUR N. JOHNSON, M. Am. Soc. C. E., State Highway Engineer of Illinois, on December 13th delivered an illustrated lecture on "Cement-Concrete Highway Bridges" before the graduate students in Highway Engineering at Columbia University.

FRANCIS P. SMITH, M. Am. Soc. C.E., Chemical and Consulting Paving Engineer, New York City, on December 20th, delivered an illustrated lecture on "The Mining and Refining of Asphaltic Oils" before the graduate students in Highway Engineering at Columbia University.

D. J. ROBERTS, of Montreal, general manager of the Napierville Junction Railway, and general manager and general freight and passenger agent of the Quebec, Montreal and Southern, has been elected president of the United States Express Company, with headquarters at New York, which office has been vacant since the death of the late Thomas C. Platt. Mr. Roberts is fifty-nine years old. He is well known to American railway men, having been in the service of the Pennsylvania Lines and the Erie from 1873 to 1901. For the ten years from 1891 to 1901 he was general passenger agent of the Erie.

OBITUARY.

WILLIAM JOHNSON BARCLAY, general manager of the Canadian Northern Quebec, the Quebec and Lake St. John, the Halifax and Southwestern and the Inverness Railway and Coal Company, with headquarters at Montreal, Quebec, died on December 13th, at Riverside, Cal., at the age of sixty-one.

COMING MEETINGS.

AMERICAN WOOD PRESERVERS' ASSOCIATION.—Ninth Annual Convention will be held at Chicago Jan. 21-23, 1913. Secy-Treasurer, F. J. Angier, Mount Royal Station, B. & O. R. R., Baltimore, Md.

AMERICAN INSTITUTE OF CONSULTING ENGINEERS.—Annual Meeting, January 14th, 1912, will be held at The Engineers Club, 32 West Fortieth Street, New York, N.Y. Secretary, Eugene W. Stern, 103 Park Avenue, New York.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Annual Meeting will be held on Jan 28th, 29th, and 30th, 1913, at the Society's new headquarters, 176 Mansfield St., Montreal. Secretary, C. H. McLeod.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving: Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright Secretary, Mr. Hugh B. Fergusson, 911 Rogers Building, Vancouver, B.C. Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor [illegible]; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, [illegible]; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy: Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers: Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only, unless otherwise noted, at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
1-18	—Trunk Sewer Extension, Edmonton, Alta. (P. & S.)	12-19

TENDERS

Halifax, N.S.—E. H. Armstrong, Commissioner of Public Works and Mines, will receive sealed tenders up to noon December 31st, 1912, for the construction of a wood bridge at Waverly Bog, Waverly, Halifax County. Plans, specifications, forms of tender, and all information, may be seen at the office of the Road Commissioner at Halifax, and also by application to the following parties: Parker Archibald, County Clerk, Halifax; James Murphy, merchant, Waverly, S. W. Lydiard, Road Inspector, Dartmouth

Ottawa, Ont.—R. C. Desrochers, Secretary, Department of Public Works, will receive sealed tenders for the construction of a lock, dam, regulation sluices and approach piers and the excavation of a raceway and channel in the East River, near New Glasgow, N.S., up to 4 p.m., January 20th, 1913. Plans, specification and form of contract can be seen and forms of tender obtained at this department and at the offices of J. L. Michaud, Esq., district engineer, Merchants Bank Building, Montreal; A. R. Decary, Esq., district engineer, Post Office, Quebec; F. G. Goodspeed, Esq., district engineer, St. John, N.B.; C. E. W. Dodwell, Esq., district engineer, Halifax, N.S., and on application to the postmaster at New Glasgow, N.S.

Ottawa, Ont.—R. C. Desrochers, Secretary, Department of Public Works, will receive sealed tenders for the construction of six steel hopper scows, 300 yards' capacity each, up to 4 p.m., Tuesday, January 7th, 1913. Plans, specification and form of contract can be seen and forms of tender obtained at this Department and at the offices of T. H. Schwitzer, Esq., Mechanical Superintendent, Birks Building, Ottawa, Ont.; J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont.; C. E. W. Dodwell, Esq., District Engineer, Halifax, N.S., and H. H. Donnelly, Esq., Superintendent of Dredges, St. John, N.B.

Ottawa, Ont.—Alex. Johnson, Deputy-Minister of Marine and Fisheries, Ottawa, will receive sealed tenders up to noon, January 31st, 1913, for the construction of a first-class, single-screw, steel, steam lightship, 114 feet in length. Plans, tender forms and specifications of this lightship can be seen at the office of the Purchasing Agent of the Marine and Fisheries Department, Ottawa; at the offices of the Collectors of Customs, Toronto, Collingwood and Port Arthur, Ont., and at the Agencies of the Department of Marine and Fisheries at Montreal, Quebec, St. John, N.B., and Halifax, N.S.

Ottawa, Ont.—Tenders for the construction of six 300 cubic yards' capacity steel hopper scows, will be received at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa, until January 7th, 1913. (See advertisement elsewhere in The Canadian Engineer).

Ottawa, Ont.—P. E. Ryan, Secretary. The Commissioners of the Transcontinental Railway, will receive sealed tenders up to noon on February 13th, 1913, for machines, tools, appliances, motors, furnaces, cranes, etc., required for the equipment of the car department shops at Transcona, Manitoba. Specifications and forms of tender may be seen at the offices of Mr. W. J. Press, Mechanical Engineer, Ottawa.

Ottawa, Ont.—G. J. Desbarats, Deputy Minister of the Naval Service, Ottawa, will receive sealed tenders up to noon January 15th, 1913, for a schooner conforming to the following dimensions.—Length over all about 98 ft. 6 inch; length of water line, 80 ft.; beam, 20 ft.; mean draft, 8 ft. Schooner to be delivered alongside wharf at H.M.C. dockyard, Esquimalt, B.C. Copies of the design and specification can be obtained on application to the above, or to the Naval Store Officer at H.M.C. Dockyard, Esquimalt.

Saskatoon, Sask.—Mr. G. H. Clare will receive sealed tenders for the construction of the Presbyterian College to be erected on the grounds of the University of Saskatchewan at Saskatoon. Plans may be seen at the Builders' Exchange at Winnipeg and Regina, and at the office of Brown and Vallance, Saskatoon

Saskatoon, Sask.—Tenders for the construction of buildings on the Forest Nursery Station, Saskatoon, Sask., will be received at the office of R. C. Desrochers, secretary, Department of Public Works, Ottawa, until January 8th, 1913. Plans, etc., can be obtained at the office of the Clerk of Works, Regina, Sask., or on application to the Superintendent of the Nursery Station, Saskatoon, Sask., and at the Office of Public Works, Ottawa.

Vancouver, B.C.—The management of the Investors' Guarantee Corporation are calling tenders for the erection of a 15-story office building. Messrs. Russell, Babcock and Rice are the architects.

Vancouver, B.C.—The Bridges and Railways Committee will receive sealed tenders up to January [illegible]th, [illegible] m., for the construction of the proposed new Georgia-Harris concrete bridge.

Victoria, B.C.—W. Galt, city purchasing agent, will receive sealed tenders up to 4 p.m. Monday, January 27th, 1913, for supplies such as general supplies (hardware), brass goods, lead pipe, castings, hydrants, valves, sewer bricks, sewer pipe (vit.), Portland cement, cluster light globes, tungsten lamps, carbons, as required by the municipality. Plans and specifications may be obtained at the city purchasing agent's office.

Windsor, Ont.—R. C. Desrochers, Secretary, Department of Public Works, Ottawa, will receive sealed tenders up to 4 p.m., January 13th, 1913, for the construction of a wharf at Windsor, Ont. Plans, specifications and form of contract can be seen and forms of tender obtained at this Department and at the offices of H. J. Lamb, Esq., District Engineer, Windsor, Ont.; and J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont.

Winnipeg, Man.—Sealed tenders addressed to the Chairman, Board of Control, and endorsed on the envelope "Tender for Stepdown Transformers," will be received at the office of M. Peterson, Secretary, Board of Control, Winnipeg, up to 11 a.m. on Friday, January 24th, 1913, for the manufacture and installation in the Terminal Station, Winnipeg, of three 2,700 K.W. Stepdown Transformers with oil and accessories complete. Plans, etc., at the Civic Light and Power Department, 54 King St., Winnipeg.

Winnipeg, Man.—Tenders addressed to the Chairman, Board of Control, Winnipeg, for the supply of from 500 to 1,000 electric flat irons, will be received until noon, January 6th, 1913. Full instructions may be obtained at the office of the City, Light and Power Department, 54 King Street. M. Peterson, secretary, Board of Control office, Winnipeg.

Woodlands, Man.—Maj. J. Proctor, Secretary-Treasurer Rural Municipality of Woodlands, will receive sealed tenders up to January 6th, 1913, for the construction of drains. The estimated amount of excavation is 140,000 cubic yards. Plans and specifications may be seen at the office of the above, or at Department of Public Works, Winnipeg.

◆

CONTRACTS AWARDED

Big Bay Point, Ont.—Wharf with stone approach: Contractor, Henry Hickey, Peterborough, Ont.

◆

RAILWAYS—STEAM AND ELECTRIC.

Eastern Canada.—A deputation will proceed to Ottawa to urge the government to double track the Intercolonial Railway, or, if not, to hand the same over to a private company.

London, Ont.—It is reported that the Canadian Northern Railway will increase its offer to this city regarding the London and Port Stanley Railway. At present a graduated scale of rental which would average $34,000 a year for the road—$14,000 higher than any rental the city has received—is being offered. The terms asked is 83 years, but it is stated that the new offer will reduce the term of rental.

Nelson, B.C.—The Dominion Railway Board have ordered the Great Northern Railway to erect a depot at Salmo, near this point.

Port Arthur, Ont.—The street railway operating here now have 19 first-class passenger cars in operation; these are in addition to several old cars.

◆

LIGHT, HEAT AND POWER

Halifax, N.S.—A lighting contract between the municipal council and the Halifax Tramway Company has been signed for a term of three years.

◆

GARBAGE, SEWAGE AND WATER.

Calgary, Alta.—Dr. Mahood, civic health officer, has advised the citizens to boil all water used for domestic purposes.

Regina, Sask.—It is made quite evident, from the report of the commissioners, that Regina will have to depend upon flowing wells for a water supply for some time to come.

Toronto, Ont.—A sewage pumping plant to cost $43,000 has been authorized by the Board of Control. It will be erected at the foot of Morley Avenue.

BUILDINGS AND INDUSTRIAL WORKS.

Arrowhead, B.C.—Mr. T. C. Southworth, president of the Minnesota Pulp and Fibre Mills of Minneapolis, is considering the erection of a branch plant in this section during the coming spring.

Berlin, Ont.—The special committee appointed to select a site for a new Y.W.C.A. building has decided upon the Kaufman property on Water Street north at $10,000. Plans for the new structure will be drawn immediately to cost $25,000.

Calgary, Alta.—The Canadian Inspection and Testing Laboratories, Ltd., of Montreal, will locate a cement testing plant in the Lougheed Building, Calgary.

Halifax, N.S.—It is reported that the Canadian Pacific Railway will erect a large hotel in this city.

Hamilton, Ont.—The Hamilton Malleable Iron Company, with a capital of $600,000, controlled by Canadians, will erect a plant in this city at an early date. Mr. J. E. Hammond will be managing director. They will employ about 500 men at the start.

Hamilton, Ont.—The management of the Mercury Mills, Limited, are considering the establishment of a plant here for the manufacture of hosiery and underwear. John Penman, Paris, Ont., is interested in the project.

Lethbridge, Alta.—The management of the Lethbridge Creamery Company, Ltd., will erect a modern creamery in this city. Messrs. A. and L. A. Rigimbal are interested.

Medicine Hat, Alta.—It is reported that the B. Scragge and Metal Company, of Winnipeg, will erect a plant in this city.

Moose Jaw, Sask.—Mr. H. C. Struchen, of Saskatoon, will develop a large gravel pit located 26 miles south of this city. He will spend $45,000 on this work.

Moose Jaw, Sask.—Mr. L. Thomas, of Messrs. Thomas and Company, is interested in a project calling for the erection of a $650,000 hotel.

Ottawa, Ont.—It is reported that a substantial sum will be voted by the Federal Government, after Christmas, in order that a start may be made on the long-talked-of Georgian Bay Canal.

Port Arthur, Ont.—The Port Arthur Club has decided to erect a new club house on Cameron St., to cost not less than $60,000; J. J. O'Conner, President.

St. Thomas, Ont.—Messrs. Thomas Brothers are considering the enlargement of their factory at on expenditure of $30,000.

St. Thomas, Ont.—The management of the Sterling Diamond Cut Glass Company of Ottawa are negotiating with the council of this municipality regarding the establishment of a factory at this point.

Toronto, Ont.—It is reported that the ice dealers of this city will erect a plant for the artificial manufacture of ice capable of turning out 100 tons per day.

Vancouver, B.C.—Dr. J. W. Powell has taken out a permit for the erection of a $47,000 apartment house.

Victoria, B.C.—It is reported that work will start on the depot of the Great Northern Railway, to be erected at False Creek, in about six months' time. Mr. Hogeland is arranging the preliminary details.

◆

BRIDGES, ROADS AND PAVEMENTS.

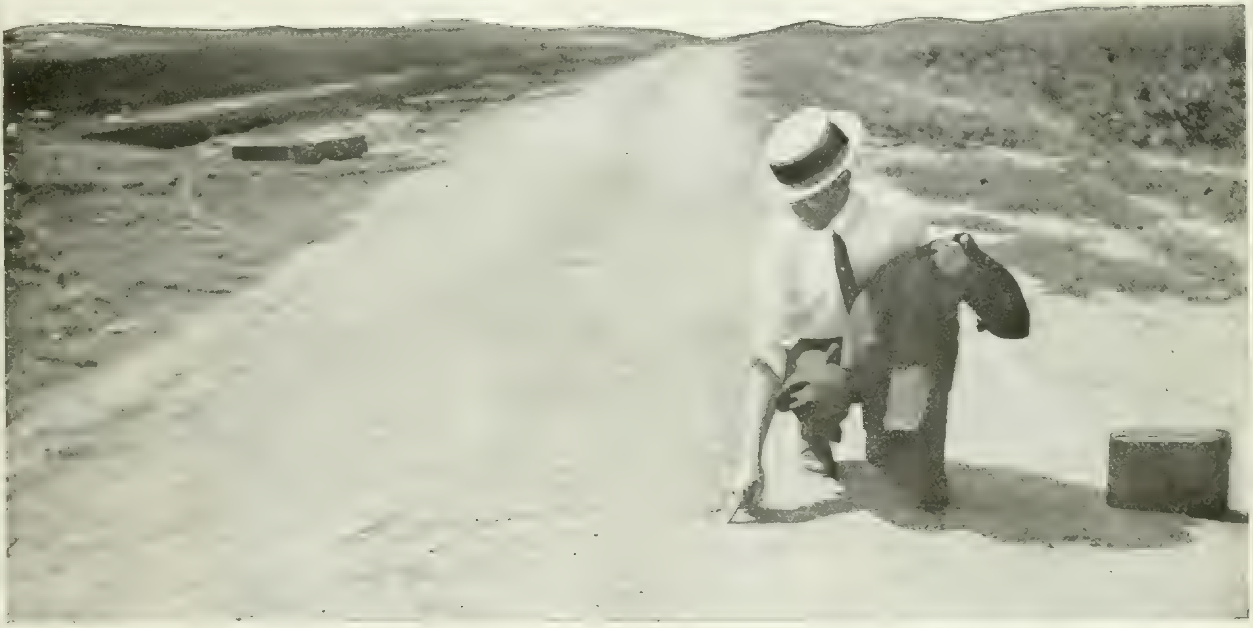
London, Ont.—The Municipal Park Commissioners have adopted a scheme calling for a boulevard drive around the city. Commissioner Hamilton is the originator of the idea.

Port Arthur, Ont.—A representative of the Ontario Department of Lands, Forests and Mines has been in this city preparing a report on the needs of the surrounding country regarding good roads.

Slocan City, B.C.—The provincial government will erect a bridge across the creek at Appledale. J. H. Forde, government engineer.

Tarvia

Preserves Roads
Prevents Dust~



Country Club Road, Greenvil S.C. Built with Tarvia X.

What the Government Found Out About Tarvia

THE Office of Good Roads, U.S. Department of Agriculture, built an experimental road at the country club at Greenville, S.C., in 1909, following very closely our specifications for two-coat penetration work, using "Tarvia X."

After two years the above photograph of the road was taken at a point where it adjoins a stretch of plain macadam. The intention of the Department was to find out just how much difference the Tarvia treatment made.

The picture tells the story. The plain macadam in the foreground is *worn out*. The tarviated surface is in *perfect condition*, and the difference is so great that a clear division line is seen in the above photograph.

This is a typical instance of the success of Tarvia as a road binder. A tarviated road is automobile proof, waterproof, dustless and mudless. It is so much cheaper to maintain that the cost of using Tarvia in the construction is more than compensated for.

Tarvia is made in three grades:

- "Tarvia X" for use in constructing roads and pavements.
- "Tarvia A" for hot surface applications.
- "Tarvia B" (applied cold) for dust prevention and road preservation.

Tarvia Booklet mailed free to anyone interested. Address our nearest office.

THE PATERSON MANUFACTURING COMPANY, LIMITED

CURRENT NEWS.

Calgary, Alta.—The municipal commissioners are considering engaging the services of an electrical expert to supervise the additions to the power plant that are to be made during the next few months, also the services of a water expert to take charge of the municipal supply.

Kincardine, Ont.—In his report to the council the Medical Health Officer, Dr. J. McCrimmon, requests a public abattoir, an isolation hospital, and a municipal system of garbage collection.

New Westminster, B.C.—Actual work on the municipal gas plant will be started in the spring, and before the end of 1913 the city of New Westminster will have municipal water, electric light and gas to supply to its citizens.

◆

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the Office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending December 9th, 1912:—

A North of England firm producing green slates wish to get into touch with firms at Montreal, Toronto, Quebec and Ottawa, having connections with architects, builders and slate merchants, and open to undertake their representation.

A Swedish importer desires to enter into business relations with a Canadian firm of flour millers.

From the branch for city trade inquiries, 73 Basinghall Street, E.C.

A Midlands firm are anxious to get into touch with Canadian shippers of spruce to Bristol, who can quote for their requirements.

An Italian manufacturing association wish for the addresses of first-class Canadian manufacturers' agents who import cotton yarns and cotton tissues.

A Midlands firm manufacturing waterproof motor covers, aprons, and rugs, and also carriage rugs of various descriptions, wish to be placed in communication with Canadian importers.

◆

A NEW REFRACTORY CEMENT THAT WITHSTANDS 3100 DEGREES FAHR.

Until within the last few years, fire-clay has been most generally used for laying up brick walls, cementing joints, patching and lining of furnaces, kilns, retorts, etc., where high temperatures are encountered. In spite of its exceedingly short term of usefulness, and the consequent necessity for repeatedly patching and repairing, founders and furnace men have until recently continued to use this material because there has been no substitute which could be generally used. Oft-times the fire-clay was mixed with certain other materials to serve as "binders." Of course, this "mixing" or compounding entailed considerable trouble and labor, but there had apparently been no alternative than to follow precedent.

[illegible] whose [illegible] known in recent years, has recently put on the market what they term "J M High Temperature Cement No. 31," which it is said can be used practically whenever working temperatures range between 1500° and 3100° Fahr.

This new material is a dry powder mixture composed of asbestos and other materials of secret preparation. It is mixed with water to the proper consistency (say about 18 to 20 lbs. of water to 100 lbs. of powder) for working like mortar or tamping around molds.

When used for setting up fire-brick for boilers and furnaces, lining and roofing furnaces of various kinds, or moulded into door jambs, lining fire doors, repairing side walls of [illegible] mechanical strength. When air dried, it will withstand a crushing strain of 883.5 lbs. per square inch. It vitrifies at the comparatively low temperature of [illegible] Fahr., and has a high melting point (3182° Fahr.). Being semi-acid in character, it can be used with chrome bricks, silica bricks and fire-clay bricks. It is claimed that experiments conducted with this cement show that it can be successfully used in building doors of angle iron framework without backing, or for making one-piece linings for gas or oil burning crucible furnaces.

◆

MERCURY MILLS, LIMITED.

A company of approximately a million dollars capital, has been formed and will manufacture fine hosiery and underwear, which will be sold to the retail trade.

The officials and directors of the company are: Mr. John Penman, the founder of the Penman Company, Paris, Ontario, who retired in 1906 upon the reorganization of the corporation. Mr. Richard Thompson, formerly general manager of the Penman's Limited and Mr. H. G. Smith, who was in charge of the fine hosiery mill of this company.

A four-story and basement brick building on Park Street, North formerly occupied by the Princess Underwear Company, has been purchased from the Eagle Knitting Company. This plant, however, will be of a temporary nature for it is the purpose of the organizers to purchase property and erect a mill embodying the most up-to-date ideas in construction and equipment. They expect to commence operations early in the new year and will employ 100 hands at the start. When the new factory is erected they will employ between 400 and 500 hands.

◆

HAMILTON MALLEABLE IRON COMPANY.

The Hamilton Malleable Iron Company, has been formed with a capital of $600,000 consisting of Toronto, Hamilton and Brantford capital. Although the company has not definitely decided on a site, they have three sites under option in the east and west end of the city. The names of the officials and directors of the company are withheld in the meantime, but Mr. J. E. Hammond, formerly with Pratt and Letchworth Company, Limited, Brantford, for 12 years as manager will be one of the directors and assume management of the plant. The new concern will conduct a general malleable iron business and the output will consist principally of malleable iron castings for railroad, agricultural and miscellaneous work for custom trade. The plant will cost in the neighborhood of ¼ of a million dollars and will employ about 500 hands, a large number of which will be skilled mechanics.

The plant will be in operation by July 1st, 1913, and the temporary office of the company is in the Sun Life Building.

WETTLAUFER MIXERS

are carried in stock in all sizes; if you need a mixer quickly to finish that work before the really cold weather, telephone or telegraph us, and we will place it on your work immediately.

We have manufactured concrete mixers and concrete machinery of all kinds for many years; also previously had taken contracts for concrete work of all kinds, and have had the actual experience of just what a concrete mixer should do. Wettlaufer Mixers are perfect to-day through the help of the hundreds of contractors who purchased the Wettlaufer Mixers in past years. We have gone personally to them and watched these machines working on all classes of work, asked the contractors their opinions, and so have evolved the present perfect mixer.

If you expect ever to purchase a concrete mixer, write now for our catalogue. Compare the simplicity of our mixer with other makes. The main points in favor of our mixer are its thoroughness, simplicity and durability. The Wettlaufer Mixer is of the heart-shaped drum type; this means quick and positive mixing, also the saving of power.

NEW HAVEN-GRAND TRUNK DEAL.

The New Haven-Grand Trunk deal continues to evoke considerable discussion in the United States, and especially in New England. Questions have been put by the Boston Post to Mr. Charles S. Mellen, president of the New Haven. They and the answers thereto are as follow:

Who first suggested the traffic agreement between the New Haven and Grand Trunk, yourself or President Chamberlin of the Grand Trunk? A. I do not recall. Impossible to say.

Did President Chamberlin refuse to sign the agreement? A. Yes.

Is there any secret understanding which does not appear in the text of the agreement made public by the New Haven? A. None whatever, neither now or at any previous time.

Why did you fight so hard to keep the Grand Trunk out of Providence and Boston? A. We never have been opposed to the Grand Trunk extensions. We have only fought to keep the use of our tracks and terminals to ourselves, as they are insufficient for our own business, and to allow another to use them would force us to secure new capital for their accommodation.

Did you suggest that the Grand Trunk should cease work on its New England extensions? A. No, never.

Would you be willing to have the Grand Trunk as an active competitor, owning its own rails to Boston? A. If it will come without taking our tracks and terminals, yes.

Would the Grand Trunk entering Boston on its own rails, give New England better transportation facilities than would be provided by the New Haven-Grand Trunk traffic agreement? A. I do not think it would.

Do you ever think of quitting the fight in Boston? A. I have no fight with the people of Massachusetts. I am fighting for them. I am looking, not to the immediate present, but to the future, when the result of my work will secure their support and approbation.

Commenting upon the Grand Trunk Railway's movements in New England, the New York Journal of Commerce says:—

"At the close of the hearing before the House Rules Committee on the question of investigating the alleged agreement between the New York & New Haven and the Grand Trunk railroads, the text of the alleged agreement was submitted to the committee by the vice-president of the New Haven road. As we have already said, this was a traffic agreement proposed by President Mellen and not accepted by the president of the Grand Trunk, who wished to have some changes made in it. It makes no reference to the abandonment of the independent connections of the Grand Trunk with terminals at Boston and Providence, but it is a fair inference that it had much to do with the sudden suspension of work on the latter, notwithstanding the pretense that this was due to financial reasons. It contains nothing to incriminate Mr. Mellen and takes all force out of his offer to waive any right to immunity in testifying about it, as nothing was accomplished.

"Whatever the effect of the agreement might be if it were to be adopted, there is no violation of law in making the proposal. There is nothing unusual in the terms offered. It was proposed to establish certain through routes, joint rates and through billing by an arrangement for each railroad to run trains over certain lines belonging to the other, which would doubtless be of advantage to both and might under proper regulation be of advantage to the public. It ought to be of advantage to avoid duplication of facilities and expense, and to provide continuous service and through rates on routes belonging to different companies, always provided that the facilities be sufficient, the service adequate and the rates just and reasonable.

"There lies the difficulty. As the two systems through New England lie, there is more or less competition between them, and with the contemplated extensions of the Grand Trunk that competition would be materially increased. If those extensions were completed and an agreement should then be made, whereby the competition was suppressed, there is hardly a doubt that this would be held to be a violation of the anti-trust law. There are plenty of precedents to indicate that. If the proposed agreement were to be effected it would stop such competition as may exist and prevent that which was contemplated by the proposed extensions. There is little doubt that it would prevent the extensions from being made or that such was the intention in proposing it. The exposure caused by the suspension of work on the line to Providence has probably prevented the adoption of an agreement which would have been in violation of law, but we do not see how the Grand Trunk can be compelled to make the extensions and establish a competition which does not now exist."

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

18226—December 5—Recommending to the Governor-in-Council for sanction the Indenture of Lease, dated October 2nd, 1912, between the Alberta Central Railway and the C.P.R. Company.

18227—December 3—Authorizing C.P.R. to construct spur for the Alex. Bremer, Limited, on Lot Cadastral No. 125, Parish of St. Felix de Valois, Co. Joliette, Que., mileage 14.83 from Lanoraie, St. Gabriel Subdivision.

18228—December 4—Approving C.L.O. and W. (C.P.R.) plan 'A' showing details of structure to be constructed across road between Cons. 7 and 8, Tp. Hichinbrooke, near Parham, mileage 32.54.

18229—December 5—Authorizing C.N.R. to construct Craven Northeasterly Line across Eight (8) highways in Saskatchewan

18230—December 5—Authorizing C.N.R. to construct Maryfield Branch across Fourteen (14) highways in Prov. Saskatchewan.

18231—December 5—Authorizing G.T.P. to construct siding for the Dunnville Brick and Tile Company, Tp. Moulton, Co. Haldimand, Ontario.

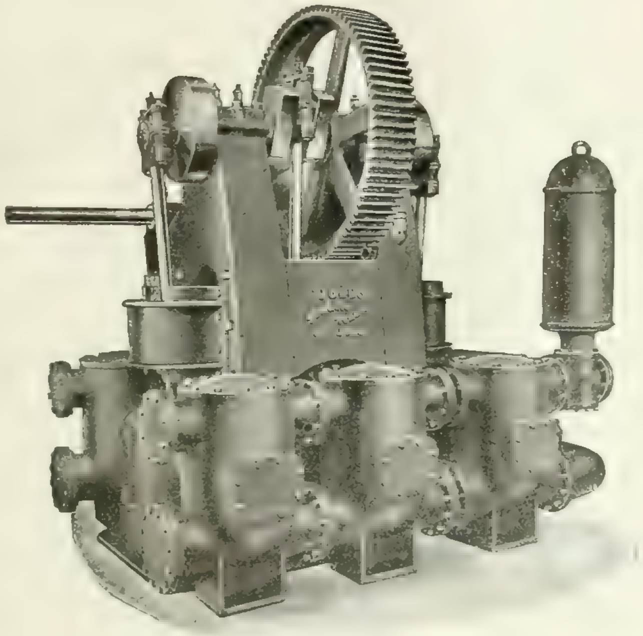
Goulds Fig. 1590 Triplex Pump

For General Water Supply, Fire Protection, Elevator, Condenser and other General Services.



This pump is of the double-acting type and will deliver nearly twice as much water as a single acting pump of the same cylinder diameter and stroke.

It is furnished regularly in capacities ranging from 10,500 to 91,500 gallons per minute, for pressures up to 150 pounds or 350 feet elevation.

It is suitable for all services where large capacities are required.

Our line includes all types of Goulds Single and Double-Acting Triplex Pumps for all services. They are suitable for belt or direct connection to any type of driver.

ASK FOR BULLETINS.
